MEDICINE

Contents

Anaesthesia and Critical Care	22
1. Acute Pain Management	22
2. Anaemia	26
3. Arrhythmias	30
4. Atrial Arrhythmias.....	35
5. Atrial Fibrillation (AF)	40
6. Cardiogenic Shock	44
7. Complete Heart Block (Third-Degree Heart Block)	48
8. Distributive Shock	52
9. Emergence from Anaesthesia	56
10. Essential and Secondary Hypertension	60
11. Evaluation of the Deteriorating Patient.....	64
12. Heart Failure	68
13. Hypovolaemic Shock	72
14. Hypoxia.....	75
15. Induction of Anaesthesia	79
16. Ischaemic Heart Disease	84
17. Maintenance and Monitoring During Anaesthesia	88
18. Multi-Organ Dysfunction Syndrome (MODS)	92
19. Obstructive Shock	97
20. Post-Operative Nausea and Vomiting (PONV)	101
21. Respiratory Arrest.....	106
22. Respiratory Failure.....	109
23. Substance Misuse Disorder	114
24. Valvular Heart Disease.....	118
25. Ventricular Tachycardia (VT)	123
Breast disease	127
26. Breast Abscess and Mastitis	127
27. Breast Cancer	131
28. Breast Cysts	136
29. Fibroadenoma	140
30. Benign Breast Disease	143
Care of the Elderly.....	147
31. Assessment of Needs and Discharge Planning.....	147
32. Blackouts and Faints	151

33.	Breakdown in Social Circumstances	156
34.	Chronic Cognitive Impairment.....	161
35.	Delirium (Acute Confusional State)	166
36.	Dementia	171
37.	Dizziness.....	176
38.	Elder Abuse	181
39.	Faecal Incontinence	186
40.	Falls	191
41.	Fluid and Electrolyte Imbalance	196
42.	Frailty	202
43.	Immobility	207
44.	Infection.....	213
45.	Interface and Community Care	219
46.	Mental Capacity Concerns.....	224
47.	Multifactorial Falls Management	229
48.	Orthogeriatrics	234
49.	Osteoporosis.....	240
50.	Parkinson's Disease – Comprehensive Revision Notes	245
51.	Pressure Sores and Skin Ulcers	250
52.	Sensory Impairment: Hearing Loss and Visual Loss.....	255
53.	Stroke	261
54.	Surgical Liaison	267
55.	Urinary Incontinence	272
56.	Vertigo	278
	Cardiology	284
57.	Angina.....	284
58.	Acute Coronary Syndrome (ACS)	287
59.	Cardiac Arrest	290
60.	Atrial Fibrillation (AF)	293
61.	Atrial Arrhythmias	297
62.	Atrioventricular (AV) Block	300
63.	Ventricular Tachycardia (VT)	303
64.	Acute Heart Failure	308
65.	Chronic Heart Failure.....	311
66.	Hypertension.....	314
67.	Infective Endocarditis	317

68.	Pericardial Disease	320
69.	Cardiac Tamponade	324
70.	Acute Pericarditis	326
71.	Pericardial Effusion.....	329
72.	Constrictive Pericarditis.....	332
73.	Aortic Valve Disease	334
74.	Mitral Valve Disease.....	337
75.	Right Heart Valve Disease	340
76.	Myocarditis	343
77.	Cardiomyopathy	346
	Dermatology.....	350
78.	Atopic Dermatitis (Atopic Eczema	350
79.	Irritant Contact Dermatitis	352
80.	Allergic Contact Dermatitis	355
81.	Erythroderma	358
82.	Other Types of Eczema (Dermatitis).....	361
83.	Melanoma.....	364
84.	Squamous Cell Carcinoma (SCC).....	367
85.	Basal Cell Carcinoma (BCC)	370
86.	Actinic Keratosis (AK)	373
87.	Bowen's Disease	376
88.	Cutaneous Lymphoma.....	379
89.	Melanocytic Naevi (Moles)	383
90.	Seborrhoeic Keratoses.....	385
91.	Impetigo.....	388
92.	Erysipelas	391
93.	Cellulitis.....	394
94.	Necrotizing Fasciitis	397
95.	Folliculitis	401
96.	Herpes Simplex Virus (HSV)	404
97.	Varicella Zoster Virus (VZV)	408
98.	Viral Warts.....	411
99.	Fungal Infections	414
100.	Scabies	418
101.	Head Lice.....	421
102.	Urticaria (Hives).....	424

103.	Stevens-Johnson Syndrome (SJS)	427
104.	Toxic Epidermal Necrolysis (TEN).....	430
105.	Drug Eruptions	433
106.	Dermatomyositis	436
107.	Neurofibromatosis.....	440
108.	Tuberous Sclerosis	444
109.	Cutaneous Manifestations of Malignancy	448
110.	Vasculitis	451
111.	Erythema Nodosum.....	455
112.	Erythema Multiforme	458
113.	Pyoderma Gangrenosum	461
114.	Venous Ulcers	464
115.	Pemphigus Vulgaris	467
116.	Bullous Pemphigoid	470
117.	Rosacea	474
118.	Psoriasis	477
119.	Acne Vulgaris	480
	Endocrine.....	484
120.	Type 1 Diabetes Mellitus	484
121.	Type 2 Diabetes Mellitus	487
122.	Gestational Diabetes Mellitus (GDM).....	490
123.	Pre-Existing Diabetes in Pregnancy.....	492
124.	Diabetic Ketoacidosis (DKA).....	496
125.	Hyperosmolar Hyperglycaemic State (HHS).....	498
126.	Diabetic Nephropathy.....	501
127.	Diabetic Neuropathy.....	504
128.	Diabetic Retinopathy	507
129.	Diabetes Insipidus	510
130.	Hypothyroidism	513
131.	Thyrotoxicosis	516
132.	Thyroid Cancer	519
133.	Thyroid Eye Disease (TED)	522
134.	Thyroid Nodules	525
135.	Addison's Disease	528
136.	Cushing's Syndrome.....	531
137.	Conn's Syndrome (Primary Hyperaldosteronism)	534

138.	Cushing's Disease	537
139.	Pituitary Tumours	540
140.	Hyperparathyroidism	544
141.	Hypoparathyroidism	547
142.	Hypercalcaemia	550
143.	Hypocalcaemia	553
144.	SIADH (Syndrome of Inappropriate Antidiuretic Hormone Secretion)	555
145.	Malignant Hyperpyrexia	558
146.	Poisoning and Overdose	562
147.	Polycystic Ovarian Syndrome (PCOS) and Hirsutism	565
148.	Hyperlipidaemia	569
149.	Obesity	573
ENT		577
150.	Cholesteatoma.....	577
151.	Epiglottitis	581
152.	Epistaxis	586
153.	Foreign Body	590
154.	Head and Neck Carcinoma	595
155.	Infectious Mononucleosis	600
156.	Laryngitis	605
157.	Ménière's Disease	610
158.	Nasal Trauma	614
159.	Otitis Externa.....	619
160.	Otitis Media	623
161.	Pinna Hematoma.....	628
162.	Presbycusis.....	633
163.	Rhinosinusitis and Nasal Polyps.....	639
164.	Tonsillitis and Pharyngitis	648
165.	Vocal Cord Paralysis	654
Gastrointestinal		660
166.	Gastrointestinal (GI) Bleeding.....	660
167.	Colorectal Tumours	663
168.	Inflammatory Bowel Disease (IBD)	665
169.	Diverticular Disease: Comprehensive Revision Notes	669
170.	Malabsorption	672
171.	Coeliac Disease	674

172.	Helicobacter pylori	677
173.	Infectious Colitis	680
174.	Irritable Bowel Syndrome (IBS)	683
175.	Functional Dyspepsia	685
176.	Malnutrition.....	688
177.	Enteral and Parenteral Feeding.....	691
178.	Eating Disorders	694
179.	Gastric Cancer	697
180.	Gastro-Oesophageal Reflux Disease (GORD) and Hiatus Hernia.....	701
181.	Peptic Ulcer Disease (PUD) and Gastritis	704
182.	Oesophageal Cancer	708
183.	Achalasia	711
184.	Eosinophilic Oesophagitis (EoE).....	715
185.	Gallstones and Biliary Colic	718
186.	Acute Pancreatitis	722
187.	Chronic pancreatitis	725
188.	Pancreatic Cancer	729
189.	Acute Hepatic Failure	733
190.	Acute Hepatitis.....	736
191.	Alcoholic Hepatitis	740
192.	Cirrhosis	744
193.	Non-Alcoholic Fatty Liver Disease (NAFLD).....	748
194.	Viral Hepatitis.....	751
195.	Autoimmune Hepatitis.....	755
196.	Drug-Induced Hepatitis.....	759
197.	Ascites.....	763
198.	Haemochromatosis.....	767
199.	Hepatocellular Carcinoma (HCC) and Liver Metastasis	771
200.	Metastatic Disease	776
201.	Appendicitis	781
202.	Cholecystitis	784
203.	Acute Cholangitis	788
204.	Gastrointestinal Perforation	792
205.	Peritonitis.....	796
206.	Intestinal Ischaemia	801
207.	Intestinal Obstruction and Ileus	805

208.	Volvulus	810
209.	Gallstones and Biliary Colic	814
210.	Gastrointestinal Surgery: Hepatobiliary and Pancreatic Surgery.....	818
211.	Hiatus Hernia	823
212.	Colorectal Tumours	827
213.	Inflammatory Bowel Disease (IBD)	832
214.	Anal Fissure.....	836
215.	Haemorrhoids	840
216.	Perianal Abscesses and Fistulae	844
217.	Hernias	849
218.	Abdominal Trauma	853
	Haematology	857
219.	Acquired Factors for Venous Thromboembolism (VTE)	857
220.	Anaemia of Chronic Disease (ACD)	862
221.	Anaemia of Coagulation and Its Disorders	866
222.	Management of an Anticoagulated Patient with Bleeding.....	872
223.	Blood Transfusion	877
224.	Haematological Cancers	883
225.	Chronic Liver Disease and Its Haematological Manifestations	888
226.	Essential Thrombocythemia.....	894
227.	Haemochromatosis and Iron Overload	899
228.	Autoimmune Haemolytic Anaemia (AIHA).....	904
229.	Sickle Cell Disease (SCD) and Haemolytic Anaemia.....	910
230.	Thalassaemia and Haemolytic Anaemia	915
231.	Haemolytic Anaemia	921
232.	Haemolytic Disease of the Newborn (HDN)	926
233.	Haemophilia.....	931
234.	Haemorrhagic Disease of the Newborn (Vitamin K Deficiency Bleeding - VKDB)	936
235.	High INR and Bleeding	941
236.	Hyposplenism and Splenectomy.....	946
237.	Immune Thrombocytopaenia (Gestational).....	951
238.	Neonatal Immune Thrombocytopaenia (NITP).....	956
239.	Infection in Haematology	961
240.	Inherited Thrombophilia.....	966
241.	Leucocytosis	971
242.	Leukaemia	977

243.	Leukemoid Reaction	983
244.	Lymphocytosis, Lymphadenopathy, and Splenomegaly.....	987
245.	Macrocytic Anaemia	993
246.	Microcytic Anaemia	998
247.	Multiple Myeloma	1003
248.	Myeloproliferative and Myelodysplastic Disorders.....	1009
249.	Neutropenia	1016
250.	Neutropenic Sepsis	1021
251.	Pancytopenia	1026
252.	Polycythaemia.....	1032
253.	Pulmonary Embolism (PE) and Deep Vein Thrombosis (DVT).....	1036
254.	Thrombotic Thrombocytopenic Purpura (TTP)	1039
255.	Transfusion Reactions	1043
256.	Von Willebrand's Disorder (VWD)	1048
	Immunology	1052
257.	Autoimmune Diseases.....	1052
258.	Primary and Secondary Immune Deficiency.....	1062
	Infection	1071
259.	Bacterial Vaginosis	1071
260.	Candidiasis	1074
261.	Chlamydia.....	1078
262.	COVID-19	1082
263.	Fungal Infections	1087
264.	Antibiotic Stewardship.....	1095
265.	Genital Tract Infections and Sexually Transmitted Diseases.....	1098
266.	Healthcare Associated Infections.....	1101
267.	Herpes Simplex Virus.....	1107
268.	HIV/AIDS	1113
269.	Human Herpes Viruses	1119
270.	Human Papillomavirus (HPV)	1129
271.	Infections in the Immunocompromised	1135
272.	Influenza	1142
273.	LGV, Donovanosis, and Chancroid.....	1148
274.	Lower Respiratory Tract Infections.....	1154
275.	Lyme Disease	1161
276.	Notifiable Diseases	1166

277.	Pyrexia of Unknown Origin (PUO)	1171
278.	Traveller's Diarrhoea	1178
279.	Tuberculosis (TB)	1185
280.	Vaccination and Immunisation	1195
281.	Viral Hepatitis	1200
Gynaecology		1206
282.	Adenomyosis	1206
283.	Anovulatory Cycles	1212
284.	Atrophic Vaginitis	1218
285.	Bacterial Vaginosis (BV)	1223
286.	Cervical Cancer	1228
287.	Cervical Screening (HPV)	1233
288.	Chlamydia	1237
289.	Congenital Adrenal Hyperplasia (CAH)	1242
290.	Contraception	1247
291.	Dysfunctional Uterine Bleeding (DUB)	1253
292.	Endometrial Cancer	1258
293.	Endometriosis	1262
294.	Fertility and Subfertility	1267
295.	Fibroids (Uterine Leiomyomas)	1273
296.	Hypogonadism	1279
297.	Menopause	1285
298.	Ovarian Cancer	1291
299.	Pelvic Inflammatory Disease (PID)	1296
300.	Polycystic Ovarian Syndrome (PCOS)	1301
301.	Premenstrual Syndrome (PMS)	1306
302.	Toxic Shock Syndrome (TSS)	1311
303.	Unwanted Pregnancy and Termination of Pregnancy	1316
304.	Urinary Incontinence	1321
305.	Urinary Tract Infection (UTI)	1327
306.	Vaginal Prolapse	1332
307.	Vulval and Vaginal Cancer	1338
Obstetrics		1344
308.	Cord Prolapse	1344
309.	Ectopic Pregnancy	1346
310.	Epilepsy	1350

311.	Essential and Secondary Hypertension in Obstetrics	1354
312.	Hydatidiform Mole and Choriocarcinoma	1358
313.	Hyperemesis Gravidarum	1362
314.	Labour	1365
315.	Miscarriage	1369

Anaesthesia and Critical Care

1. Acute Pain Management

1. Detailed Definition of Acute Pain Management

Acute pain is the body's normal response to injury, surgery, or illness and typically lasts for a short duration (up to a few weeks). It serves as a **protective mechanism**, alerting the individual to harm or potential damage. The goal of **acute pain management** is to provide effective pain relief, improve patient comfort, and enable early mobilisation, while minimising the risk of chronic pain development and adverse effects from analgesia.

2. Common Presenting Complaints and Symptoms

a) Pain Characteristics:

Sudden onset of pain following:

Trauma (e.g., fractures, soft tissue injury)

Surgical procedures (post-operative pain)

Acute illness (e.g., pancreatitis, myocardial infarction)

Localized pain:

Acute pain is often well-localized to the area of injury or inflammation.

Sharp, stabbing, or throbbing pain:

Descriptions of pain can vary based on the underlying cause, but acute pain is often described as intense and sharp.

b) Associated Symptoms:

Increased heart rate, blood pressure:

Acute pain may trigger a **sympathetic response**, leading to tachycardia and hypertension.

Anxiety and restlessness:

Patients may feel anxious due to the intensity of pain.

Reduced mobility:

Pain, especially post-operatively, can reduce a patient's ability to move or participate in rehabilitation.

3. First-Line Investigations

a) Clinical Assessment:

Pain history:

Onset, duration, intensity (using pain scales like the **Visual Analogue Scale (VAS)** or **Numeric Rating Scale (NRS)**), **quality**, and **location** of pain.

Physical examination:

Assess the **site of injury**, **range of motion**, and any associated signs like **swelling**, **redness**, or **bruising**.

b) Monitoring Vital Signs:

Heart rate, blood pressure, and respiratory rate:

Check for changes associated with **pain** and **stress response**.

Oxygen saturation:

May need to monitor if the patient is using **opioids** for pain relief, which can cause **respiratory depression**.

4. Explanation of Investigations

Pain scales (e.g., VAS, NRS): Used to quantify the patient's subjective experience of pain, which helps guide treatment and monitor progress.

Vital signs monitoring: Helps assess the impact of pain on the body, especially regarding the **sympathetic response** and the potential effects of pain medication, such as opioids, on **respiration**.

5. Diagnostic Criteria for Acute Pain

Acute pain is diagnosed based on:

Subjective report: Patient-reported symptoms of pain following surgery, trauma, or illness.

Objective signs: Clinical findings such as **tenderness, swelling**, or abnormal **vital signs**.

Pain scale assessment: A **VAS** or **NRS** score of moderate to severe intensity (usually 4 or higher on a 10-point scale).

6. First-Line Therapy According to Guidelines

The management of acute pain is based on the **WHO analgesic ladder**, which provides a stepwise approach to analgesia depending on the severity of pain. The goal is to use the **lowest effective dose** of analgesics and to **individualise treatment** based on the patient's needs and response.

a) Mild Pain (VAS/NRS score 1-3):

Non-opioid analgesics:

Paracetamol (500 mg-1 g every 4-6 hours; maximum 4 g/day) is the first-line treatment for mild pain.

Consider **NSAIDs** (e.g., **ibuprofen 400-600 mg 3 times a day**) if there are no contraindications, such as renal impairment or peptic ulcer disease.

b) Moderate Pain (VAS/NRS score 4-6):

Paracetamol + NSAID:

Combine **paracetamol** with an **NSAID** (e.g., **ibuprofen** or **naproxen**) for more effective pain control.

Weak opioids:

Codeine (30-60 mg every 4-6 hours) or **tramadol** (50-100 mg every 4-6 hours) may be added if pain persists.

c) Severe Pain (VAS/NRS score 7-10):

Strong opioids:

Morphine (2.5-10 mg IV every 2-4 hours) or **oxycodone** for more severe pain. Dosages should be adjusted based on patient response and monitored for side effects like **respiratory depression** and **sedation**.

Patient-controlled analgesia (PCA):

PCA devices allow patients to self-administer opioids, such as **morphine** or **fentanyl**, within prescribed limits.

d) Adjunctive Therapy:

Regional anaesthesia:

Nerve blocks or **epidural analgesia** may be appropriate for post-operative pain or trauma-related pain.

Adjuvant medications:

Consider **gabapentin** or **pregabalin** for **neuropathic pain** components.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

NSAIDs:

Avoid in patients with **renal impairment**, **peptic ulcer disease**, or a history of **gastrointestinal bleeding**.

Opioids:

Use with caution in patients with a history of **substance misuse**, **respiratory conditions**, or **sleep apnoea**, due to the risk of **respiratory depression**.

b) Second-Line Therapy:

Opioid alternatives:

Ketamine (low-dose) may be used in opioid-tolerant patients or as an adjunct to opioids for acute pain management.

Intravenous lidocaine:

Can be considered in patients with **neuropathic pain** or those not responding to traditional therapies.

8. Routine Monitoring and Follow-Up

Pain reassessment: Regularly reassess the patient's pain using a pain scale to adjust treatment as needed.

Monitoring for side effects: Especially for **opioid-related** side effects like **constipation**, **respiratory depression**, or **nausea**.

Vital signs: Continuous monitoring of **respiratory rate**, **oxygen saturation**, and **blood pressure** is essential when using opioids.

9. Complications of Acute Pain Management

Respiratory depression: A serious complication of **opioid use**, especially in patients with **underlying respiratory disease**.

Addiction and tolerance: Prolonged use of opioids can lead to **dependence** and the need for **higher doses** to achieve the same effect.

Gastrointestinal complications: **Constipation** is a common side effect of opioids, and **NSAIDs** can cause **gastritis** or **peptic ulcer disease**.

Chronic pain: Poorly managed acute pain can lead to **chronic pain syndromes**.

Summary of Key Points for Acute Pain Management

Acute pain is a normal response to injury, surgery, or illness and is typically short-lived.

Pain management involves a **stepwise approach** using the **WHO analgesic ladder**, starting with **non-opioids** and escalating to **opioids** if necessary.

Paracetamol and **NSAIDs** are first-line treatments for mild to moderate pain.

Opioids may be required for severe pain, with careful monitoring for adverse effects.

Patient-controlled analgesia (PCA) and **regional anaesthesia** are effective for managing severe post-operative or trauma-related pain.

Regular **pain reassessment** and **monitoring for complications** is essential in managing acute pain effectively.

2. Anaemia

1. Detailed Definition of Anaemia

Anaemia is a condition in which there is a **decrease in the number of red blood cells (RBCs)** or the **haemoglobin (Hb) concentration** in the blood, resulting in reduced oxygen-carrying capacity. Anaemia can be classified based on **mean corpuscular volume (MCV)** into **microcytic**, **normocytic**, or **macrocytic** anaemia, and by underlying aetiology such as **iron deficiency**, **vitamin B12/folate deficiency**, or **chronic disease**.

2. Common Presenting Complaints and Symptoms

a) General Symptoms:

Fatigue and weakness:

The most common symptoms due to reduced oxygen delivery to tissues.

Pallor:

Pale skin or mucous membranes, particularly noticeable in the **conjunctiva**.

Dyspnoea:

Shortness of breath on exertion due to reduced oxygen-carrying capacity.

Dizziness or light-headedness:

Especially when standing up, due to reduced oxygen supply to the brain.

Palpitations:

A result of the heart compensating for reduced oxygen delivery by increasing cardiac output.

b) Specific Symptoms Based on Aetiology:**Iron deficiency anaemia:**

Pica (craving for non-food items like ice or dirt), **brittle nails**, **glossitis**, and **angular cheilitis**.

Vitamin B12 deficiency:

Neurological symptoms such as **paraesthesia** and **cognitive impairment** due to involvement of the nervous system.

Anaemia of chronic disease:

Symptoms related to the underlying chronic condition, such as **inflammatory** or **infectious** diseases.

3. First-Line Investigations**a) Full Blood Count (FBC):****Haemoglobin level:**

Decreased in anaemia, the normal range is typically:

Men: 130-180 g/L

Women: 115-165 g/L

Mean Corpuscular Volume (MCV):

Used to classify anaemia:

Microcytic (< 80 fL): Commonly due to **iron deficiency** or **thalassaemia**.

Normocytic (80-100 fL): May be caused by **acute blood loss**, **anaemia of chronic disease**, or **haemolysis**.

Macrocytic (> 100 fL): Often due to **vitamin B12** or **folate deficiency**.

Red cell distribution width (RDW):

Elevated in **iron deficiency** and **mixed anaemia** (e.g., vitamin B12 and iron deficiency).

b) Additional Blood Tests:

Iron studies:

Serum ferritin: Low in **iron deficiency** anaemia; elevated in **anaemia of chronic disease**.

Serum iron and **total iron-binding capacity (TIBC)** can also help assess iron status.

Vitamin B12 and Folate levels:

Low B12 indicates deficiency due to **pernicious anaemia** or **malabsorption**.

Low folate is commonly caused by **dietary deficiency** or **malabsorption**.

Reticulocyte count:

Elevated in **haemolytic anaemia** or **acute blood loss** as the bone marrow increases RBC production.

c) Bone Marrow Biopsy:

Considered in cases of **unexplained anaemia** or suspected **bone marrow disorders** such as **aplastic anaemia** or **leukaemia**.

4. Explanation of Investigations

MCV: Helps classify the anaemia and narrow down potential causes.

Serum ferritin: Reflects the body's iron stores; low in iron deficiency anaemia but may be normal or high in inflammatory conditions.

Vitamin B12: Important for DNA synthesis; deficiency leads to **megaloblastic anaemia** with macrocytosis.

Reticulocyte count: A measure of bone marrow activity and RBC production.

5. Diagnostic Criteria for Anaemia

Anaemia is diagnosed based on **haemoglobin levels** below the normal reference range:

Men: Hb < 130 g/L

Women: Hb < 115 g/L

Further classification is based on **MCV** and **underlying cause** (e.g., iron deficiency, vitamin B12 deficiency, or anaemia of chronic disease).

6. First-Line Therapy According to Guidelines

Management depends on the **type of anaemia** and its **underlying cause**.

a) Iron Deficiency Anaemia:

Oral iron replacement:

Ferrous sulphate 200 mg tablets (65 mg elemental iron) taken **2-3 times daily** for at least 3-6 months to replenish iron stores. Side effects include **constipation, black stools**, and **abdominal discomfort**.

Ferrous fumarate and **ferrous gluconate** are alternatives with fewer gastrointestinal side effects.

Dietary advice:

Encourage consumption of **iron-rich foods** such as red meat, leafy greens, and iron-fortified cereals.

Parenteral iron:

Consider in patients who cannot tolerate oral iron or have severe malabsorption.

b) Vitamin B12 or Folate Deficiency:

Vitamin B12:

Hydroxocobalamin 1 mg IM injection every 2-3 days for 2 weeks, then maintenance every 2-3 months.

Folic acid:

Folic acid 5 mg once daily for 4 months, particularly in cases of **dietary deficiency**.

c) Anaemia of Chronic Disease:

Treat the underlying cause:

Optimise management of the chronic disease (e.g., rheumatoid arthritis, chronic kidney disease).

Erythropoiesis-stimulating agents (ESAs):

Consider for anaemia due to **chronic kidney disease**.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Iron therapy:

Oral iron should be used cautiously in patients with a history of **gastrointestinal bleeding, peptic ulcers**, or **haemochromatosis**.

Vitamin B12 therapy:

Monitor for **hypokalaemia** during treatment of severe B12 deficiency due to rapid cell turnover.

b) Second-Line Therapy:

Intravenous iron:

Used in cases where **oral iron** is not tolerated or in patients with **malabsorption**.

Blood transfusion:

Reserved for patients with **severe symptomatic anaemia** (Hb < 70 g/L) or acute blood loss.

8. Routine Monitoring and Follow-Up

Regular blood tests: Monitor **haemoglobin**, **MCV**, **iron studies**, or **vitamin B12/folate** levels depending on the type of anaemia.

Iron replacement: Continue for 3-6 months after haemoglobin normalises to replenish iron stores.

9. Complications of Anaemia

Cardiovascular strain: Prolonged anaemia can cause **tachycardia** and **heart failure**, especially in older adults.

Neurological complications: In **vitamin B12 deficiency**, untreated anaemia can lead to **irreversible neurological damage**.

Pregnancy complications: Severe anaemia during pregnancy can result in **preterm delivery** or **low birth weight**.

Summary of Key Points for Anaemia

Anaemia is defined as low **haemoglobin** concentration, with causes classified by **MCV** into **microcytic**, **normocytic**, and **macrocytic** types.

Common symptoms include **fatigue**, **pallor**, **dyspnoea**, and **dizziness**.

Iron deficiency is the most common cause, followed by **vitamin B12/folate deficiency** and **anaemia of chronic disease**.

First-line treatment includes **oral iron** for iron deficiency, **B12 injections** for B12 deficiency, and **folic acid** for folate deficiency.

Monitoring includes **haemoglobin** levels and replenishing iron/B12 stores after correcting the anaemia.

3. Arrhythmias

1. Detailed Definition of Arrhythmias

Arrhythmias refer to any abnormality in the rate, rhythm, or conduction of the heart's electrical impulses. They can cause the heart to beat too fast (**tachyarrhythmias**), too slow

(**bradyarrhythmias**), or irregularly. Arrhythmias can arise from problems in the **sinoatrial node (SA node)**, **atrioventricular node (AV node)**, or the **ventricular conduction system**.

2. Common Presenting Complaints and Symptoms

a) Palpitations:

A common symptom where patients feel an abnormal sensation of their heartbeat, often described as **racing**, **fluttering**, or **thumping**.

b) Dizziness and Syncope:

Due to **impaired cardiac output**, arrhythmias can lead to **light-headedness**, **dizziness**, or even **syncope (fainting)**.

c) Shortness of Breath (Dyspnoea):

Arrhythmias can impair the heart's ability to pump blood efficiently, leading to symptoms of **dyspnoea**, particularly on exertion.

d) Chest Pain or Discomfort:

Ischaemic heart disease or arrhythmias causing rapid heart rates may cause **angina** or chest pain.

e) Fatigue and Weakness:

Due to reduced cardiac output, patients may feel **fatigued** or **lethargic**, especially during physical activities.

3. First-Line Investigations

a) Electrocardiogram (ECG):

The **gold standard** for diagnosing arrhythmias.

Key findings may include:

Atrial fibrillation (AF): Absent P waves, irregularly irregular QRS complexes.

Ventricular tachycardia (VT): Broad, abnormal QRS complexes at a rate > 100 bpm.

Atrioventricular block: Prolonged PR intervals or dropped QRS complexes (in **Mobitz II** or **complete heart block**).

Supraventricular tachycardia (SVT): Narrow QRS complexes with a rapid heart rate.

b) Ambulatory ECG Monitoring:

24-hour Holter monitor or **event monitor** is useful for detecting arrhythmias that are intermittent and not captured on a single ECG.

c) Blood Tests:

Electrolytes: Imbalances in **potassium**, **magnesium**, or **calcium** can precipitate arrhythmias.

Thyroid function tests: Particularly important in patients with **atrial fibrillation** as **hyperthyroidism** is a potential cause.

Cardiac biomarkers (e.g., troponin): May be indicated if myocardial infarction or **myocardial ischaemia** is suspected.

d) Echocardiogram:

Evaluates the structure and function of the heart to assess for **valvular disease**, **cardiomyopathy**, or **heart failure**, which may predispose patients to arrhythmias.

e) Electrophysiology Study (EPS):

A specialised test to map the heart's electrical activity, often used when **ablation therapy** is considered.

4. Explanation of Investigations

ECG: Detects electrical abnormalities, providing a visual representation of arrhythmias.

Ambulatory ECG: Captures transient arrhythmias that may not be present during a short-term ECG.

Echocardiogram: Assesses the mechanical function of the heart and underlying structural abnormalities that may contribute to arrhythmias.

5. Diagnostic Criteria for Common Arrhythmias

a) Atrial Fibrillation (AF):

ECG features:

Absent **P waves**.

Irregularly irregular ventricular rhythm.

Rate may vary (usually 100-180 bpm if uncontrolled).

b) Supraventricular Tachycardia (SVT):

ECG features:

Narrow **QRS complexes**.

Heart rate typically between **150-250 bpm**.

No clear **P waves**, or they are retrograde.

c) Ventricular Tachycardia (VT):

ECG features:

Wide **QRS complexes** (>120 ms).

Monomorphic or **polymorphic** patterns, with rates often > 120 bpm.

d) Atrioventricular (AV) Block:

First-degree block: PR interval > **200 ms** (prolonged).

Second-degree block (Mobitz I/Wenckebach): Progressive prolongation of the PR interval until a **QRS is dropped**.

Second-degree block (Mobitz II): Constant PR interval with **intermittent dropped QRS complexes**.

Third-degree (complete) block: No association between **P waves** and **QRS complexes**.

6. First-Line Therapy According to Guidelines

The management of arrhythmias varies based on the type of arrhythmia, the severity of symptoms, and the risk of complications such as **stroke** or **heart failure**.

a) Atrial Fibrillation (AF):

Rate control:

Beta-blockers (e.g., **bisoprolol** 2.5-10 mg once daily) or **calcium channel blockers** (e.g., **diltiazem**) are first-line agents.

Digoxin is an alternative for patients with heart failure.

Rhythm control:

Antiarrhythmic drugs like **amiodarone** or **flecainide** may be used for patients where rhythm control is preferred.

Electrical cardioversion is an option for rhythm restoration.

Anticoagulation:

To reduce the risk of **stroke**, anticoagulation is recommended based on the **CHA2DS2-VASc score**.

First-line agents include **direct oral anticoagulants (DOACs)** such as **apixaban** or **warfarin** if not suitable for DOACs.

b) Supraventricular Tachycardia (SVT):

Acute management:

Vagal manoeuvres (e.g., **Valsalva** technique) may terminate the arrhythmia.

Adenosine (6 mg IV, then 12 mg if needed) is used to acutely terminate SVT.

Long-term management:

Beta-blockers or **calcium channel blockers** may prevent recurrent episodes.

Catheter ablation can be considered if episodes are frequent or symptomatic.

c) Ventricular Tachycardia (VT):

Acute management:

If the patient is **haemodynamically unstable**, immediate **DC cardioversion** is required.

Amiodarone or **lidocaine** can be used for pharmacological cardioversion.

Long-term management:

Implantable cardioverter-defibrillator (ICD) may be indicated in patients with recurrent VT or underlying heart disease.

Antiarrhythmic medications (e.g., **amiodarone**) for those at risk of recurrent episodes.

d) Bradyarrhythmias (AV Block):

First-degree block: Usually **no treatment** required unless symptomatic.

Mobitz II or complete heart block:

Patients require **permanent pacemaker insertion**, especially if symptomatic or haemodynamically unstable.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:****Beta-blockers:**

Avoid in patients with **asthma** or severe **COPD**.

Calcium channel blockers:

Avoid in patients with **heart failure** with reduced ejection fraction (HFrEF).

Adenosine:

Should be avoided in patients with **Wolff-Parkinson-White syndrome**.

b) Second-Line Therapy:**Catheter ablation:**

May be indicated in recurrent or drug-refractory **AF**, **SVT**, or **VT**.

ICD (Implantable Cardioverter-Defibrillator):

Indicated for high-risk patients with **ventricular arrhythmias** or those with a history of **sudden cardiac arrest**.

8. Routine Monitoring and Follow-Up

ECG monitoring: Regular ECGs to assess response to treatment or recurrence of arrhythmias.

Anticoagulation monitoring: For patients on **warfarin**, regular **INR** monitoring is required.

Drug levels: Monitoring levels of **antiarrhythmic drugs** (e.g., **digoxin**, **amiodarone**) to avoid toxicity.

9. Complications of Arrhythmias

Stroke: Common in patients with **AF** due to **embolisation** of a clot from the atria.

Heart failure: Tachyarrhythmias can cause or exacerbate **heart failure**.

Sudden cardiac arrest: Can occur in patients with **VT** or **ventricular fibrillation (VF)**.

Summary of Key Points for Arrhythmias

Arrhythmias are abnormal heart rhythms that may be classified as **tachyarrhythmias** (fast) or **bradyarrhythmias** (slow).

Common symptoms include **palpitations**, **dizziness**, **syncope**, and **chest pain**.

ECG is the gold standard for diagnosis.

Management involves controlling the **rate** or **rhythm**, and in some cases, **anticoagulation** to reduce stroke risk.

Ablation and **pacemaker** or **ICD** insertion may be required for certain types of arrhythmias.

4. Atrial Arrhythmias

1. Detailed Definition of Atrial Arrhythmias

Atrial arrhythmias are abnormal heart rhythms originating from the atria, the upper chambers of the heart. These include conditions such as **atrial fibrillation (AF)**, **atrial flutter**, and **supraventricular tachycardia (SVT)**. These arrhythmias can cause irregular, rapid heartbeats, leading to impaired blood flow and an increased risk of complications such as **stroke** or **heart failure**.

2. Common Presenting Complaints and Symptoms

a) Palpitations:

Sensation of **irregular, rapid, or pounding heartbeats**, commonly associated with **AF** or **SVT**.

b) Fatigue and Weakness:

Reduced cardiac output may lead to **fatigue**, especially with exertion.

c) Dizziness or Lightheadedness:

Due to **reduced blood flow to the brain**, particularly in patients with **atrial flutter** or **AF** with rapid ventricular response.

d) Shortness of Breath (Dyspnoea):

Especially during exertion, due to reduced **cardiac output** and poor oxygenation.

e) Chest Discomfort or Pain:

Some patients may experience **angina-like chest pain** due to the increased oxygen demand of the heart during rapid rhythms.

f) Syncope or Pre-Syncope:

Rare but can occur if the arrhythmia significantly reduces blood flow, particularly in **paroxysmal SVT** or **AF** with rapid ventricular response.

3. First-Line Investigations

a) Electrocardiogram (ECG):

The **primary diagnostic tool** for identifying atrial arrhythmias.

Atrial fibrillation (AF): Irregularly irregular rhythm, absent P waves.

Atrial flutter: Regular rhythm with characteristic **sawtooth P waves**.

Supraventricular tachycardia (SVT): Narrow QRS complex tachycardia, often with an absent or retrograde P wave.

b) Ambulatory ECG Monitoring (Holter Monitor):

Used to detect **paroxysmal atrial arrhythmias** (e.g., **paroxysmal AF**, **paroxysmal SVT**) if symptoms are intermittent and not present on standard ECG.

c) Blood Tests:

Thyroid function tests: Hyperthyroidism is a common reversible cause of **AF**.

Electrolytes: To detect **hypokalaemia**, **hypomagnesaemia**, or **hypercalcaemia**, which can trigger arrhythmias.

Full blood count (FBC): To rule out infection or anaemia as potential triggers.

d) Echocardiogram:

Assesses the **structure** and **function** of the heart, particularly in patients with **new-onset arrhythmias** or signs of **heart failure**.

Checks for **valvular disease**, **left atrial enlargement**, or **left ventricular dysfunction**.

e) Electrophysiology Study (EPS):

Considered for complex cases or when planning **catheter ablation** to pinpoint the origin of the arrhythmia.

4. Explanation of Investigations

ECG: Detects the **type of atrial arrhythmia** and evaluates rate, rhythm, and conduction.

Holter Monitor: Useful for detecting **intermittent** arrhythmias, especially in **paroxysmal AF** or **SVT**.

Thyroid function tests: Hyperthyroidism can precipitate atrial arrhythmias.

Echocardiogram: Assesses **structural abnormalities** and cardiac function, which may contribute to arrhythmia development.

5. Diagnostic Criteria for Atrial Arrhythmias

a) Atrial Fibrillation (AF):

ECG findings:

Irregularly irregular ventricular response.

Absent **P waves**.

Fibrillatory waves (seen in some leads).

AF can be classified as **paroxysmal**, **persistent**, or **permanent**.

b) Atrial Flutter:

ECG findings:

Regular rhythm with characteristic **sawtooth** flutter waves.

Atrial rate typically around **300 beats per minute**, with ventricular rate around **150 bpm** (2:1 block).

c) Supraventricular Tachycardia (SVT):

ECG findings:

Narrow QRS complex with **absent or retrograde P waves**.

Heart rate often between **150-250 bpm**.

6. First-Line Therapy According to Guidelines

The management of atrial arrhythmias depends on the **type of arrhythmia**, its **symptom burden**, and the presence of **associated complications** such as heart failure or thromboembolism.

a) Atrial Fibrillation (AF):

Rate Control:

Beta-blockers (e.g., **bisoprolol** 2.5-10 mg once daily) or **calcium channel blockers** (e.g., **diltiazem**) are first-line treatments.

Digoxin can be used for rate control, especially in patients with **heart failure**.

Rhythm Control:

Consider **antiarrhythmic drugs** (e.g., **amiodarone**, **flecainide**) for rhythm control.

Electrical cardioversion may be used for rhythm restoration in patients with recent-onset AF.

Anticoagulation:

Anticoagulation is essential to reduce the risk of **thromboembolism** in AF. The **CHA2DS2-VASc** score is used to guide anticoagulation decisions.

Preferred anticoagulants include **direct oral anticoagulants (DOACs)** (e.g., **apixaban**, **rivaroxaban**) or **warfarin** if a DOAC is contraindicated.

b) Atrial Flutter:

Rate Control:

Similar to AF, **beta-blockers** or **calcium channel blockers** are used for rate control.

Rhythm Control:

Catheter ablation is often preferred for long-term rhythm control, as atrial flutter has a high rate of recurrence.

Anticoagulation:

Patients with atrial flutter are also at risk of thromboembolism and should be anticoagulated using the **CHA2DS2-VASc score**.

c) Supraventricular Tachycardia (SVT):

Acute Management:

Vagal manoeuvres (e.g., Valsalva) are the first-line non-pharmacological approach.

Adenosine (6 mg IV bolus, repeat with 12 mg if necessary) is the drug of choice for acute termination of SVT.

Long-Term Management:

Beta-blockers or **calcium channel blockers** can be used to prevent recurrent episodes.

Catheter ablation is often considered for patients with recurrent or symptomatic SVT.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Beta-blockers:

Avoid in patients with **asthma** or **severe COPD**.

Calcium channel blockers:

Avoid in patients with **heart failure** with reduced ejection fraction (HFrEF).

Adenosine:

Contraindicated in patients with **Wolff-Parkinson-White syndrome (WPW)** due to the risk of ventricular fibrillation.

b) Second-Line Therapy:

Catheter Ablation:

For **AF**, **atrial flutter**, or **SVT**, ablation can offer long-term rhythm control and reduce the need for ongoing antiarrhythmic medications.

Amiodarone:

Used as a second-line antiarrhythmic for rhythm control in **AF** or **atrial flutter**, especially in patients with **structural heart disease**.

8. Routine Monitoring and Follow-Up

ECG monitoring: Regular ECGs to assess for arrhythmia recurrence or treatment effectiveness.

Anticoagulation monitoring: For patients on **warfarin**, regular **INR monitoring** is required. DOACs do not require regular monitoring but should be reviewed periodically.

Drug levels: **Amiodarone** levels should be monitored for long-term therapy to avoid **toxicity**.

9. Complications of Atrial Arrhythmias

Thromboembolism: Particularly in **AF** and **atrial flutter**, with increased risk of **stroke** and **systemic embolism**.

Heart failure: Rapid arrhythmias can lead to **tachycardia-induced cardiomyopathy** or exacerbate existing heart failure.

Syncope or sudden death: Uncontrolled or untreated **SVT** or **atrial fibrillation** can occasionally lead to collapse or sudden death.

Summary of Key Points for Atrial Arrhythmias

Atrial arrhythmias include **AF**, **atrial flutter**, and **SVT**, with palpitations, fatigue, and dyspnoea being common symptoms.

ECG is essential for diagnosis, and additional tests like **ambulatory monitoring**, **blood tests**, and **echocardiograms** help identify underlying causes.

Management depends on the arrhythmia type and involves **rate control**, **rhythm control**, and **anticoagulation** in high-risk patients.

Catheter ablation is a long-term treatment option for some patients with **AF**, **flutter**, or **SVT**.

Regular **ECG** monitoring and appropriate **anticoagulation** help prevent complications like **stroke** and **heart failure**.

5. Atrial Fibrillation (AF)

1. Detailed Definition of Atrial Fibrillation

Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia, characterised by rapid and irregular electrical activity in the atria, leading to an **irregularly irregular pulse** and often resulting in rapid heart rates. The atria do not contract effectively, leading to compromised blood flow and an increased risk of **thromboembolism**, particularly **stroke**.

2. Common Presenting Complaints and Symptoms

a) Palpitations:

Patients often report a sensation of **irregular, rapid heartbeats** or **fluttering** in their chest.

b) Fatigue and Weakness:

Reduced cardiac output due to ineffective atrial contraction can result in **fatigue** and **exercise intolerance**.

c) Dyspnoea (Shortness of Breath):

Patients may experience breathlessness, particularly on exertion, due to poor oxygen delivery from an irregular and rapid heart rate.

d) Dizziness or Lightheadedness:

Due to reduced cerebral blood flow during periods of rapid ventricular response.

e) Chest Discomfort:

Angina-like chest pain may occur, especially in patients with underlying coronary artery disease.

f) Syncope:

Rare, but severe cases of **tachycardia** or **bradycardia** can cause fainting due to insufficient blood flow to the brain.

3. First-Line Investigations

a) Electrocardiogram (ECG):

The **gold standard** for diagnosing atrial fibrillation.

Key features include:

Absent P waves.

Irregularly irregular QRS complexes.

Ventricular rate is often rapid, depending on AV nodal conduction.

b) Blood Tests:

Thyroid function tests: **Hyperthyroidism** is a common precipitant of AF.

Electrolytes: Low **potassium** or **magnesium** levels can trigger or exacerbate AF.

Renal function and **liver function tests** should be monitored in patients on certain anticoagulants and antiarrhythmics.

c) Echocardiogram:

Used to assess for structural heart disease, such as **valvular heart disease**, **left atrial enlargement**, or **left ventricular dysfunction**.

It also helps identify underlying causes such as **cardiomyopathy** or **heart failure**.

d) Holter Monitor or Event Recorder:

If **paroxysmal atrial fibrillation** (intermittent episodes) is suspected but not captured on a standard ECG, ambulatory ECG monitoring may be used.

4. Explanation of Investigations

ECG: A definitive diagnostic tool for detecting AF by observing irregular rhythm and the absence of P waves.

Echocardiogram: Identifies structural abnormalities that may contribute to the development of AF and helps guide management, such as the need for anticoagulation.

5. Diagnostic Criteria for Atrial Fibrillation

a) Key ECG Criteria for AF:

Irregularly irregular ventricular rhythm.

Absence of P waves and presence of **fibrillatory waves** (best seen in leads V1 or V2).

Atrial rate can range from 300-600 beats per minute, but not all impulses are transmitted to the ventricles.

b) Classification of Atrial Fibrillation:

Paroxysmal AF: Self-terminating episodes that last < 7 days (often < 24 hours).

Persistent AF: AF that lasts longer than 7 days and requires pharmacological or electrical cardioversion to restore sinus rhythm.

Permanent AF: AF that is accepted as a long-term rhythm control strategy and will not be treated with rhythm control attempts.

6. First-Line Therapy According to Guidelines

Management of AF involves a combination of **rate control**, **rhythm control**, and **stroke prevention** with anticoagulation. The choice of therapy depends on the patient's **symptoms**, **comorbidities**, and **thromboembolic risk**.

a) Rate Control:

Beta-blockers (e.g., **bisoprolol** 2.5-10 mg once daily) or **calcium channel blockers** (e.g., **diltiazem**) are first-line for controlling the ventricular rate.

These agents slow conduction through the AV node, preventing excessively rapid ventricular rates.

Digoxin: Can be considered, especially in patients with **heart failure** or those who are sedentary, but is less effective during exertion.

b) Rhythm Control:

Electrical Cardioversion:

Used to restore sinus rhythm in patients with **persistent AF** or symptomatic **paroxysmal AF**.

Pharmacological Cardioversion:

Flecainide or **amiodarone** may be used in selected patients to restore sinus rhythm, particularly in **young, structurally normal hearts**.

Catheter Ablation:

Recommended for patients with **paroxysmal AF** or those with symptomatic AF refractory to drug therapy. Ablation targets the **pulmonary vein foci**, where AF often originates.

c) Anticoagulation:

Stroke prevention is essential in patients with AF due to the increased risk of **thromboembolism**. The **CHA2DS2-VASc** score is used to stratify stroke risk.

Patients with a score of **2 or more** should receive anticoagulation.

Direct oral anticoagulants (DOACs) such as **apixaban**, **rivaroxaban**, or **dabigatran** are preferred over warfarin for most patients.

Warfarin is an alternative if DOACs are contraindicated, but regular **INR** monitoring is required.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Beta-blockers: Should be avoided in patients with **severe asthma** or **acute heart failure**.

Calcium channel blockers: Contraindicated in patients with **heart failure** with reduced ejection fraction (HFrEF).

DOACs: Not suitable for patients with **severe renal impairment** (use **warfarin** instead).

b) Second-Line Therapy:

Catheter Ablation:

Indicated for patients with **paroxysmal AF** or **persistent AF** who fail medical therapy or cannot tolerate antiarrhythmic drugs.

Amiodarone:

A second-line antiarrhythmic drug, especially for patients with structural heart disease or heart failure. It is associated with **multiple side effects** and requires close monitoring.

8. Routine Monitoring and Follow-Up

ECG Monitoring: Repeat ECGs to assess for recurrence of AF or new arrhythmias.

Anticoagulation Monitoring: Regular **INR monitoring** for patients on warfarin; routine monitoring is not needed for DOACs but should be reviewed periodically.

Renal and Liver Function: Monitoring in patients on DOACs and antiarrhythmics like **amiodarone**.

Electrolytes: Monitoring potassium and magnesium levels is essential in patients on certain antiarrhythmics.

9. Complications of Atrial Fibrillation

Stroke: The most serious complication, particularly in patients who are not anticoagulated.

Heart Failure: Rapid AF can lead to **tachycardia-induced cardiomyopathy** and exacerbate existing heart failure.

Thromboembolism: Clots formed in the atria can embolise, leading to strokes, systemic embolism, or **pulmonary embolism**.

Syncope or Sudden Death: Rare but can occur if AF is associated with other severe arrhythmias or bradycardia.

Summary of Key Points for Atrial Fibrillation

AF is the most common sustained arrhythmia and is associated with significant risks, including **stroke** and **heart failure**.

Diagnosis is based on an **ECG** showing an **irregularly irregular rhythm** and absent **P waves**.

Treatment includes **rate control** (e.g., beta-blockers, calcium channel blockers), **rhythm control** (e.g., electrical or pharmacological cardioversion), and **stroke prevention** with anticoagulation.

The **CHA2DS2-VASc score** is used to assess the risk of thromboembolism and guide the need for anticoagulation.

Long-term management may include **catheter ablation** for rhythm control in symptomatic or refractory cases.

Routine follow-up includes monitoring **ECG**, **anticoagulation**, and electrolyte levels.

6. Cardiogenic Shock

1. Detailed Definition of Cardiogenic Shock

Cardiogenic shock is a life-threatening condition where the heart is unable to pump sufficient blood to meet the body's metabolic demands, resulting in inadequate tissue perfusion and organ dysfunction. It most commonly occurs as a complication of acute myocardial infarction (AMI), but can also result from other conditions that impair cardiac function.

2. Common Presenting Complaints and Symptoms

a) Hypotension:

Systolic blood pressure <90 mmHg for more than 30 minutes despite adequate fluid resuscitation.

b) Cold and Clammy Skin:

Due to **peripheral vasoconstriction** as the body attempts to maintain blood pressure.

c) Tachycardia:

The body compensates by increasing heart rate to improve cardiac output.

d) Shortness of Breath (Dyspnoea):

Often due to **pulmonary oedema** as a result of left ventricular failure.

e) Chest Pain:

If the underlying cause is **acute myocardial infarction (AMI)**, chest pain may be present.

f) Oliguria:

Reduced urine output (oliguria) due to decreased renal perfusion.

g) Altered Mental Status:

Confusion, agitation, or drowsiness may occur due to **poor cerebral perfusion**.

3. First-Line Investigations

a) Electrocardiogram (ECG):

Used to assess for **acute myocardial infarction (AMI)** or other arrhythmias contributing to cardiogenic shock.

Look for **ST-elevation, new left bundle branch block (LBBB)**, or other signs of ischaemia.

b) Blood Tests:

Cardiac troponins: Raised in the setting of myocardial infarction, useful to confirm AMI.

BNP (B-type natriuretic peptide): Often elevated in cardiogenic shock due to heart failure.

Lactate: Increased in shock states due to anaerobic metabolism.

Arterial blood gases (ABG): Shows **metabolic acidosis**, hypoxia, and possibly elevated lactate.

c) Echocardiogram:

A critical tool for assessing **left ventricular function**, **wall motion abnormalities**, **valvular dysfunction**, or **cardiac tamponade**.

Identifies the underlying cause of shock (e.g., **severe LV dysfunction**, **mitral regurgitation**, **aortic dissection**).

d) Chest X-ray:

May show **pulmonary oedema** or **cardiomegaly**, indicative of heart failure or fluid overload.

e) Haemodynamic Monitoring:

Pulmonary artery catheter (Swan-Ganz catheter) to measure cardiac output and pulmonary artery pressures can be useful in managing complex cases.

4. Explanation of Investigations

ECG: Detects **myocardial ischaemia**, which is the most common cause of cardiogenic shock.

Echocardiogram: Assesses **cardiac function** and helps identify structural problems like valve rupture or **ventricular dysfunction**.

BNP: A hormone produced by the heart in response to pressure overload and stretching; elevated levels suggest heart failure as a cause of shock.

Lactate: Elevated in all shock states, it indicates **tissue hypoperfusion** and poor oxygen delivery.

5. Diagnostic Criteria for Cardiogenic Shock

Systolic BP <90 mmHg for at least 30 minutes.

Reduced cardiac output with **increased systemic vascular resistance (SVR)** and signs of **end-organ hypoperfusion** (e.g., cold extremities, oliguria, altered mental status).

Pulmonary capillary wedge pressure >15 mmHg (suggesting left-sided heart failure).

6. First-Line Therapy According to Guidelines

The management of cardiogenic shock focuses on **improving cardiac output**, **correcting underlying causes**, and ensuring **adequate perfusion** to vital organs. Early identification and management in **intensive care settings** is crucial.

a) General Measures:

Oxygenation:

Provide **high-flow oxygen** or initiate **mechanical ventilation** if needed to improve oxygenation and reduce the work of breathing.

Inotropes:

Noradrenaline (initial dose: 0.05-0.5 µg/kg/min) is often used to maintain blood pressure.

Dobutamine (initial dose: 2-20 µg/kg/min) is used to improve cardiac output by increasing **contractility** and **heart rate**.

Vasopressors:

Noradrenaline is the vasopressor of choice to maintain **mean arterial pressure (MAP) >65 mmHg**.

b) Management of Underlying Cause:

Acute Myocardial Infarction (AMI):

Percutaneous coronary intervention (PCI) is the preferred treatment for AMI-related cardiogenic shock, and should be performed within 90 minutes of diagnosis.

Thrombolysis can be considered if PCI is not immediately available.

Mechanical Support:

Intra-aortic balloon pump (IABP): Temporarily increases coronary perfusion and reduces afterload, particularly useful in patients with AMI or severe left ventricular dysfunction.

Left ventricular assist devices (LVADs) or **extracorporeal membrane oxygenation (ECMO)**: Considered in severe cases or when conventional treatments fail.

c) Fluid Management:

Careful fluid administration is necessary, as **fluid overload** can exacerbate **pulmonary oedema**. Monitor for signs of overload while ensuring adequate **renal perfusion**.

d) Antithrombotic Therapy:

In cases of AMI, **aspirin** (300 mg loading dose) and **clopidogrel** or **ticagrelor** should be administered to prevent further thrombus formation.

Heparin or other anticoagulants should be given during PCI.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Inotropes (e.g., dobutamine): Use with caution in patients with **tachyarrhythmias**, as these agents can worsen arrhythmias.

Volume overload: Avoid aggressive fluid resuscitation in patients with **acute pulmonary oedema** or **heart failure**.

b) Second-Line Therapy:

Mechanical Circulatory Support (e.g., ECMO):

Can be considered for patients in **refractory cardiogenic shock** when medical therapy and standard mechanical interventions (e.g., IABP) fail.

Ventricular Assist Devices (VADs):

May be required for long-term support in patients awaiting **heart transplantation**.

8. Routine Monitoring and Follow-Up

Haemodynamic monitoring: Continuous **arterial blood pressure** and **central venous pressure (CVP)** monitoring are essential to guide fluid therapy and vasoactive medication dosing.

Electrolyte monitoring: Frequent monitoring of **potassium**, **magnesium**, and **sodium** levels is necessary, especially with inotropes and diuretics.

Renal function: Assess **urine output** and serum **creatinine** to monitor for **acute kidney injury**.

Cardiac biomarkers: Regular monitoring of **troponin** and **BNP** levels to assess ongoing myocardial injury and heart failure status.

9. Complications of Cardiogenic Shock

Multiorgan failure: Prolonged shock leads to **renal failure**, **hepatic failure**, and **cerebral hypoperfusion**, causing irreversible organ damage.

Arrhythmias: Cardiogenic shock can cause **ventricular arrhythmias**, which may further compromise cardiac output.

Death: Despite optimal treatment, **cardiogenic shock** has a high mortality rate, particularly if **early revascularisation** (in cases of AMI) is not performed.

Summary of Key Points for Cardiogenic Shock

Cardiogenic shock is a critical condition characterised by **impaired cardiac output**, leading to **hypoperfusion** and **organ dysfunction**.

ECG, **echocardiography**, and **blood tests** (including cardiac biomarkers and lactate) are key to diagnosis.

Management includes **inotropes**, **vasopressors**, and **early revascularisation** (e.g., **PCI**) in cases of myocardial infarction.

Mechanical support, such as **intra-aortic balloon pump (IABP)** or **ECMO**, may be necessary in refractory cases.

Close monitoring of haemodynamic status, electrolytes, and end-organ function is critical to guide treatment.

7. Complete Heart Block (Third-Degree Heart Block)

1. Detailed Definition of Complete Heart Block

Complete heart block (third-degree atrioventricular (AV) block) occurs when there is no conduction of electrical impulses from the atria to the ventricles. As a result, the atria and ventricles beat independently of each other, with the ventricles relying on a slower, intrinsic escape rhythm to maintain cardiac output. This often leads to **bradycardia** and poor perfusion.

2. Common Presenting Complaints and Symptoms

a) Bradycardia:

Slow heart rate, typically 30-40 beats per minute, depending on the origin of the ventricular escape rhythm.

b) Fatigue and Weakness:

Due to the reduced cardiac output, patients may feel unusually **tired** or **weak** even with minimal exertion.

c) Syncope (Stokes-Adams Attacks):

Fainting episodes or loss of consciousness caused by prolonged periods of **asystole** or severe bradycardia before the escape rhythm takes over.

d) Dizziness or Lightheadedness:

Often caused by poor **cerebral perfusion** due to bradycardia.

e) Dyspnoea (Shortness of Breath):

Shortness of breath may occur due to poor oxygen delivery from reduced cardiac output.

f) Chest Pain:

In some cases, chest discomfort or **angina-like pain** may be present due to poor coronary perfusion, particularly in patients with co-existing coronary artery disease.

3. First-Line Investigations

a) Electrocardiogram (ECG):

Key diagnostic tool to confirm complete heart block.

Features include:

P waves present, but they are not related to QRS complexes (atria and ventricles beat independently).

Regular P-P intervals and **regular R-R intervals**, but with no association between the P waves and the QRS complexes.

Ventricular rate is usually slow (escape rhythm), typically 30-40 beats per minute.

b) Blood Tests:

Electrolytes: Check for **hyperkalaemia**, **hypokalaemia**, and **hypomagnesaemia**, which can cause or exacerbate heart block.

Cardiac biomarkers: Elevated **troponins** may suggest myocardial infarction as the underlying cause of complete heart block.

Thyroid function tests: Hypothyroidism can cause **bradycardia** and contribute to heart block.

c) Echocardiogram:

Performed to assess for structural heart disease, including **left ventricular function**, valvular abnormalities, or **cardiomyopathy**, which may be contributing to the development of heart block.

d) Chest X-ray:

Used to assess for evidence of heart failure (e.g., **pulmonary oedema**, **cardiomegaly**) or lung pathology that might be contributing to cardiovascular instability.

e) Holter Monitor:

Ambulatory ECG monitoring may be used if the heart block is intermittent and not captured on an initial ECG.

4. Explanation of Investigations

ECG: The definitive diagnostic test for complete heart block, showing **no relationship between atrial (P waves) and ventricular (QRS complexes) activity**.

Blood tests: Check for metabolic causes of heart block, including electrolyte imbalances and **thyroid dysfunction**.

Echocardiogram: Assesses for any underlying structural abnormalities that may contribute to heart block, such as **valvular disease** or **cardiomyopathy**.

5. Diagnostic Criteria for Complete Heart Block

Complete heart block is diagnosed based on **ECG findings**:

No conduction from the atria to the ventricles, resulting in a **dissociation between P waves and QRS complexes**.

Ventricular escape rhythm is present, often at a slow rate (30-40 bpm).

P-P intervals and **R-R intervals** remain regular, but there is no relationship between them.

6. First-Line Therapy According to Guidelines

Management of complete heart block focuses on restoring adequate cardiac output and ensuring haemodynamic stability. **Permanent pacemaker implantation** is usually required for long-term management.

a) Initial Stabilisation:

Atropine:

0.5 mg IV, can be repeated every 3-5 minutes (up to a total dose of 3 mg).

Atropine works by blocking the **vagal tone** on the heart, potentially improving heart rate in bradyarrhythmic conditions, though it is often ineffective in complete heart block.

Temporary Pacing:

Transcutaneous pacing can be used as an emergency measure until a **temporary transvenous pacemaker** can be inserted.

Temporary pacing is required for symptomatic bradycardia, particularly in patients with **syncope** or **haemodynamic instability**.

Isoprenaline (Isoproterenol):

Consider **IV isoprenaline** infusion in unstable patients who are awaiting permanent pacing.

Dose: 0.02-0.06 mg IV bolus, then 0.02-0.06 mg/min infusion titrated to response. Isoprenaline stimulates **beta-adrenergic receptors**, increasing heart rate.

b) Permanent Pacemaker Implantation:

Dual-chamber pacemaker:

Long-term treatment is almost always **pacemaker implantation**.

Dual-chamber pacemakers (with leads in both the atrium and ventricle) are preferred to maintain **AV synchrony** and improve overall cardiac function.

c) Management of Underlying Cause:

Myocardial infarction:

PCI (percutaneous coronary intervention) or **thrombolysis** may be required if the complete heart block is secondary to acute MI.

Electrolyte Correction:

Correct any electrolyte disturbances, such as **hyperkalaemia**, which may be contributing to heart block.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Atropine:

May be ineffective in complete heart block since it primarily works on the **AV node**, which is not conducting impulses in third-degree block.

Isoprenaline:

Avoid in patients with **myocardial ischaemia** as it increases **myocardial oxygen demand** and may worsen ischaemia.

b) Second-Line Therapy:

Permanent Pacemaker:

The definitive treatment for complete heart block in most cases, and generally the next step if medications (such as atropine or isoprenaline) are ineffective.

Temporary Transvenous Pacing:

Used as a bridge to **permanent pacemaker implantation** for patients who are acutely unstable and need immediate support.

8. Routine Monitoring and Follow-Up

ECG monitoring: Continuous ECG monitoring in acute settings to detect changes in heart rhythm.

Pacemaker follow-up: After pacemaker insertion, regular follow-up is needed to ensure the device is functioning correctly and appropriately managing the heart rate.

Electrolyte monitoring: Regular monitoring of **potassium, magnesium, and calcium** levels, particularly if there is an electrolyte disturbance contributing to heart block.

Renal function tests: Monitoring is necessary, especially in patients on **isoprenaline** or those with heart failure.

9. Complications of Complete Heart Block

Syncope: Due to the inadequate cardiac output from slow ventricular escape rhythms.

Sudden Cardiac Arrest: If the ventricular escape rhythm fails, the patient may suffer from **asystole**.

Heart Failure: Prolonged bradycardia and poor cardiac output can lead to the development or worsening of heart failure.

Thromboembolism: If heart failure develops, patients are at higher risk for **thromboembolic events**, such as **stroke**.

Summary of Key Points for Complete Heart Block

Complete heart block is characterised by **no conduction** between the atria and ventricles, leading to independent atrial and ventricular rhythms.

The primary symptom is **bradycardia**, leading to **syncope**, **fatigue**, and **dizziness**.

Diagnosis is based on **ECG** findings, showing no relationship between P waves and QRS complexes.

Treatment includes **immediate stabilisation** with **temporary pacing** or **medications**, followed by **permanent pacemaker implantation**.

Regular follow-up with **pacemaker monitoring** and management of any underlying causes (e.g., MI or electrolyte disturbances) is essential to prevent complications.

8. Distributive Shock

1. Detailed Definition of Distributive Shock

Distributive shock is a type of shock where there is a **failure of vascular tone**, leading to **abnormal distribution of blood flow** and inadequate tissue perfusion, despite normal or elevated cardiac output. The most common cause of distributive shock is **sepsis**, but other causes include **anaphylaxis**, **neurogenic shock**, and **adrenal crisis**.

2. Common Presenting Complaints and Symptoms

a) Hypotension:

Systolic BP < 90 mmHg or a significant drop from baseline. This is often the first sign in all types of shock, particularly in septic shock.

b) Warm and Flushed Skin:

Due to **peripheral vasodilation** (especially in early septic or neurogenic shock), the skin may feel **warm** and look **flushed**.

c) Tachycardia:

A **compensatory increase in heart rate** to maintain cardiac output in response to hypotension.

d) Altered Mental Status:

Confusion, agitation, or drowsiness due to poor **cerebral perfusion**.

e) Oliguria (Low Urine Output):

Poor renal perfusion may result in **oliguria** or **anuria**.

f) Fever:

In **septic shock**, patients often present with **fever**, although **hypothermia** can also be seen in severe cases.

3. First-Line Investigations

a) Blood Cultures:

Essential in **septic shock** to identify the causative organism and guide antimicrobial therapy.

b) Lactate Levels:

Lactate is a marker of **tissue hypoperfusion** and anaerobic metabolism, elevated in all types of shock.

c) Full Blood Count (FBC):

Look for signs of **infection** (e.g., raised **white cell count**) in septic shock, or **eosinophilia** in anaphylactic shock.

d) Coagulation Studies:

Disseminated intravascular coagulation (DIC) is a common complication in severe septic shock, making coagulation profiles (PT, APTT, fibrinogen) important.

e) Arterial Blood Gas (ABG):

Check for **metabolic acidosis** (raised lactate) and **hypoxaemia**, which indicate tissue hypoperfusion.

f) Imaging:

Chest X-ray may reveal pneumonia or other sources of infection in **septic shock**.

CT/MRI of the spine in **neurogenic shock** secondary to trauma.

4. Explanation of Investigations

Blood cultures: Used to identify the pathogen causing **septic shock**.

Lactate levels: Elevated in all shock types, indicating poor tissue oxygenation.

Coagulation studies: Useful in diagnosing **DIC**, a life-threatening complication of septic shock.

ABG: Identifies **acidosis** and evaluates overall respiratory and metabolic status.

5. Diagnostic Criteria for Distributive Shock

Septic Shock:

Hypotension despite adequate fluid resuscitation.

Serum lactate > 2 mmol/L.

Requirement for **vasopressors** to maintain **mean arterial pressure (MAP)** > 65 mmHg.

Neurogenic Shock:

Hypotension and **bradycardia** following spinal cord injury.

Warm skin due to loss of **sympathetic tone**.

Anaphylactic Shock:

Hypotension with a history of exposure to allergens, along with **bronchospasm**, **rash**, and **angioedema**.

6. First-Line Therapy According to Guidelines

a) Septic Shock:

Fluid Resuscitation:

Crystalloids (e.g., **0.9% sodium chloride**) are the first-line fluids. Initial bolus of **30 mL/kg** is recommended to maintain perfusion.

Continue fluids based on the patient's response and haemodynamic monitoring.

Antibiotics:

Administer **broad-spectrum antibiotics** within **1 hour** of recognition of sepsis (e.g., **piperacillin-tazobactam + gentamicin**).

Narrow the antibiotic therapy once cultures return.

Vasopressors:

If hypotension persists after fluid resuscitation, **noradrenaline** (starting at 0.05-0.5 µg/kg/min) is the vasopressor of choice to maintain **MAP > 65 mmHg**.

Adrenaline or **vasopressin** can be added if noradrenaline is insufficient.

b) Anaphylactic Shock:

Adrenaline:

IM adrenaline (0.5 mg, 1:1000) is the immediate treatment for anaphylaxis.

Repeat every 5 minutes as needed if symptoms persist.

Fluids:

Aggressive fluid resuscitation with **crystalloids** is required to counter the profound vasodilation.

Antihistamines and Steroids:

Chlorphenamine (10 mg IV) and **hydrocortisone** (200 mg IV) help reduce ongoing allergic responses but should be used **after** adrenaline.

c) Neurogenic Shock:

Fluids:

Initial management includes **IV fluids** to maintain blood pressure.

Vasopressors:

Noradrenaline or **dopamine** may be required to maintain **MAP > 65 mmHg**, particularly if the injury is above **T6**, leading to loss of sympathetic tone.

Bradycardia Management:

Atropine (0.5 mg IV) or temporary **pacing** if bradycardia is severe.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Excessive fluids in patients with **pulmonary oedema** or cardiac dysfunction can worsen outcomes.

Beta-blockers in anaphylactic shock, as they can block the action of adrenaline.

b) Second-Line Therapy:

Inotropes (e.g., **dobutamine**) may be required in **septic shock** if myocardial dysfunction is present.

Corticosteroids in septic shock: **Hydrocortisone** (200 mg/day) may be considered in patients who do not respond to fluids and vasopressors.

8. Routine Monitoring and Follow-Up

Haemodynamic monitoring: Continuous blood pressure, heart rate, and oxygen saturation.

Lactate clearance: Monitor lactate levels to assess response to therapy.

Renal function: Monitor urine output and serum **creatinine** for early signs of acute kidney injury.

ABG monitoring: Assess for acidosis and respiratory failure.

9. Complications of Distributive Shock

Multiple Organ Dysfunction Syndrome (MODS): Failure of multiple organs due to poor perfusion.

Acute Respiratory Distress Syndrome (ARDS): Often seen in **septic shock**, where fluid overload and pulmonary inflammation impair gas exchange.

Death: High mortality rate if not promptly recognised and treated.

Summary of Key Points for Distributive Shock

Distributive shock is caused by **failure of vascular tone**, leading to **hypotension** and poor tissue perfusion, despite adequate cardiac output.

The most common form is **septic shock**, followed by **anaphylactic** and **neurogenic shock**.

Treatment includes **fluid resuscitation**, **vasopressors**, and addressing the underlying cause (e.g., **antibiotics** for sepsis, **adrenaline** for anaphylaxis).

Monitoring lactate levels, haemodynamics, and end-organ perfusion is essential for guiding therapy.

Complications include **multiple organ dysfunction syndrome (MODS)** and **acute respiratory distress syndrome (ARDS)**, which can be fatal if not treated aggressively.

9. Emergence from Anaesthesia

1. Detailed Definition of Emergence from Anaesthesia

Emergence from anaesthesia refers to the process of regaining consciousness and the return of protective reflexes following the cessation of general anaesthesia. It is a critical phase of the perioperative period that requires close monitoring to ensure the patient transitions smoothly from the anaesthetised state to wakefulness without complications. Emergence can be classified into **three phases: early, intermediate, and late**.

2. Common Presenting Complaints and Symptoms

During emergence from anaesthesia, patients may experience various physiological and psychological responses. Common issues include:

a) Agitation or Delirium:

Emergence delirium is a transient state of confusion and disorientation that may occur in some patients.

Patients may thrash around, pull at IV lines or oxygen masks, or become combative.

b) Pain:

As the effects of anaesthesia wear off, patients may experience **postoperative pain** in the surgical area.

c) Nausea and Vomiting:

Postoperative nausea and vomiting (PONV) is common during the emergence phase, especially in patients predisposed to motion sickness or those receiving opioid analgesics.

d) Shivering (Post-Anaesthetic Shivering):

Patients may develop **shivering** due to **hypothermia** or as a thermoregulatory response post-anaesthesia.

e) Airway Compromise:

There is a risk of **airway obstruction**, especially in patients with residual neuromuscular blockade, obesity, or pre-existing respiratory conditions.

Aspiration of gastric contents may occur in patients who have not regained their protective airway reflexes.

f) Hypoxia:

Inadequate ventilation or oxygenation during the emergence phase can lead to **hypoxia**, necessitating supplemental oxygen and close monitoring.

3. First-Line Investigations

a) Pulse Oximetry:

Continuous monitoring of oxygen saturation (SpO₂) is essential during emergence to detect hypoxia early.

b) End-Tidal CO₂ (Capnography):

Provides real-time monitoring of **ventilation status** and ensures the patient is breathing adequately after the removal of the endotracheal tube.

c) Electrocardiogram (ECG):

ECG monitoring helps detect any arrhythmias or cardiovascular instability during the emergence phase.

d) Blood Pressure Monitoring:

Non-invasive blood pressure (NIBP) should be regularly monitored to detect **hypotension** or **hypertension** as the patient regains consciousness.

e) Neuromuscular Monitoring:

Train-of-four (TOF) monitoring ensures the **adequate reversal of neuromuscular blockade**, which is critical for preventing respiratory compromise.

4. Explanation of Investigations

Pulse oximetry: Essential for monitoring oxygenation and detecting **hypoxia**.

Capnography: Ensures proper ventilation, especially during the period of **extubation**.

ECG: Identifies any **cardiac arrhythmias** or changes in heart rate that could indicate complications during emergence.

Neuromuscular monitoring: Confirms full recovery from any **residual paralysis** caused by neuromuscular blocking agents.

5. Diagnostic Criteria for Complications During Emergence

Hypoxia: SpO₂ < 92% on room air.

Emergence delirium: Agitation, disorientation, or restlessness during emergence.

Airway obstruction: Stridor, snoring, or absent breath sounds with inadequate chest rise.

Shivering: Involuntary shaking or trembling.

Nausea and vomiting: Active vomiting or retching during the emergence period.

6. First-Line Therapy According to Guidelines

a) Management of Airway and Breathing:

Airway management is critical to ensure patency and prevent **aspiration**.

Supplemental oxygen: Administer oxygen via a **face mask** or **nasal cannula** to maintain SpO₂ > 94%.

Suctioning: Use suction to clear the airway of secretions or vomitus.

Airway adjuncts: If airway obstruction is present, consider using a **nasopharyngeal** or **oropharyngeal airway**.

Positive pressure ventilation: If spontaneous breathing is inadequate, provide positive pressure ventilation using a **bag-valve mask (BVM)** or reapply mechanical ventilation.

b) Reversal of Neuromuscular Blockade:

If residual paralysis is detected, administer **neostigmine** (0.04–0.08 mg/kg) with **glycopyrrolate** (0.2 mg per 1 mg of neostigmine) or use **sugammadex** (for aminosteroid-based neuromuscular blockers like rocuronium) to reverse neuromuscular blockade.

c) Management of Pain:

IV opioids (e.g., **morphine 2-5 mg IV**) for pain relief if the patient is haemodynamically stable.

Consider **non-opioid analgesics** (e.g., **paracetamol**, **NSAIDs**) or regional anaesthesia techniques to minimise opioid-related side effects.

d) Management of Nausea and Vomiting:

Ondansetron (4 mg IV) or other antiemetics (e.g., **dexamethasone** 4 mg IV) to manage PONV.

Position the patient in the **lateral recovery position** to prevent aspiration of vomit.

e) Management of Emergence Delirium:

Reassurance and **calm environments** can help manage mild emergence delirium.

For severe agitation, consider administering **midazolam** (1-2 mg IV) or **propofol** (small doses) to calm the patient.

f) Management of Shivering:

Treat shivering with **warming blankets** or drugs like **pethidine (meperidine)** (25 mg IV), which can reduce the shivering response.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Opioids: Use cautiously in patients at risk for **respiratory depression**.

Neostigmine: Use cautiously in patients with **bradycardia**, as neostigmine may exacerbate this.

b) Second-Line Therapy:

Sugammadex: For rapid and complete reversal of **steroid-based neuromuscular blockade** in cases of residual paralysis (rocuronium, vecuronium).

Dexmedetomidine: For severe **emergence delirium**, consider low-dose **dexmedetomidine** infusion for sedation without respiratory depression.

8. Routine Monitoring and Follow-Up

Oxygen saturation (SpO₂) and **capnography** should be monitored continuously during emergence.

Blood pressure and **heart rate** should be checked every 5 minutes until the patient is fully awake and stable.

Neuromuscular monitoring to ensure complete reversal of paralysis.

Pain assessments: Regular pain scores should be recorded to assess the effectiveness of analgesia.

9. Complications During Emergence

Airway Obstruction: Due to residual anaesthesia, **obesity**, or **laryngospasm**, necessitating airway management.

Respiratory depression: Caused by residual opioid effects or neuromuscular blockade, requiring respiratory support.

Hypotension or Hypertension: Blood pressure instability due to anaesthesia effects, pain, or pre-existing conditions.

Delayed Emergence: Prolonged recovery from anaesthesia, which can occur in cases of drug overdose, hypothermia, or metabolic derangements.

Summary of Key Points for Emergence from Anaesthesia

Emergence from anaesthesia involves the recovery of consciousness, airway reflexes, and physiological stability.

Airway management is critical to prevent **aspiration** and **hypoxia**.

Postoperative nausea and vomiting (PONV), **pain**, and **emergence delirium** are common issues that need to be managed appropriately.

Monitoring oxygen saturation, capnography, and neuromuscular function is essential to ensure safe emergence.

In cases of **delayed emergence** or complications, consider underlying causes such as drug overdose or **metabolic abnormalities**.

10. Essential and Secondary Hypertension

1. Detailed Definition of Hypertension

Hypertension is defined as a persistent elevation in blood pressure (BP). It is classified into two main categories:

Essential (primary) hypertension: This accounts for **90-95% of cases** and has no identifiable secondary cause. It is thought to arise from a combination of genetic and environmental factors.

Secondary hypertension: Hypertension with a **known underlying cause**, such as renal disease, endocrine disorders, or medications.

2. Common Presenting Complaints and Symptoms

Most patients with **hypertension** are **asymptomatic** and diagnosed during routine screening. However, in more severe or long-standing cases, the following symptoms may occur:

a) Asymptomatic:

The majority of patients with hypertension have **no symptoms**.

b) Headache:

Severe hypertension (especially if diastolic BP > 120 mmHg) may cause **morning headaches**.

c) Dizziness or Visual Disturbances:

Blurring of vision or **dizziness** can occur in hypertensive crises or prolonged poorly controlled hypertension.

d) Shortness of Breath (Dyspnoea):

May result from left ventricular dysfunction caused by long-term hypertension leading to **heart failure**.

e) Chest Pain:

Angina or **chest discomfort** due to increased workload on the heart in chronic hypertension.

f) Palpitations:

Some patients report **awareness of heartbeats** or palpitations, often due to hypertensive heart disease or arrhythmias.

3. First-Line Investigations

a) Blood Pressure Measurement:

Clinic BP reading: A persistent systolic BP ≥ 140 mmHg or diastolic BP ≥ 90 mmHg indicates hypertension. For accurate diagnosis, the use of **ambulatory blood pressure monitoring (ABPM)** or **home blood pressure monitoring (HBPM)** is recommended:

Stage 1 hypertension: ABPM or HBPM $\geq 135/85$ mmHg.

Stage 2 hypertension: ABPM or HBPM $\geq 150/95$ mmHg.

b) Urinalysis:

Urine dipstick to check for **proteinuria** or **haematuria**, which may indicate underlying renal disease.

c) Blood Tests:

Renal function tests: Serum urea and electrolytes (to detect renal causes of hypertension such as chronic kidney disease).

Fasting glucose: To assess for **diabetes**, which is commonly associated with hypertension.

Lipid profile: Elevated **cholesterol** levels are often found in patients with hypertension.

d) Electrocardiogram (ECG):

To check for **left ventricular hypertrophy (LVH)**, arrhythmias, or evidence of **ischaemic heart disease**.

e) Echocardiogram:

Performed if there is evidence of left ventricular hypertrophy or suspected hypertensive heart disease to assess cardiac function.

4. Explanation of Investigations

ABPM or HBPM: Essential for diagnosing **hypertension** and avoiding "white coat hypertension" (elevated BP in clinical settings but normal at home).

Urinalysis: Detects kidney involvement or secondary causes such as **glomerulonephritis**.

Blood tests: Assess for **diabetes**, dyslipidaemia, and kidney function, which are important in the management and assessment of cardiovascular risk.

5. Diagnostic Criteria for Hypertension

According to **NICE guidelines (2019)**, the diagnostic criteria for hypertension are:

Stage 1 Hypertension: Clinic BP $\geq 140/90$ mmHg, confirmed by ABPM or HBPM $\geq 135/85$ mmHg.

Stage 2 Hypertension: Clinic BP $\geq 160/100$ mmHg, confirmed by ABPM or HBPM $\geq 150/95$ mmHg.

Severe Hypertension: Clinic systolic BP ≥ 180 mmHg or diastolic BP ≥ 120 mmHg.

6. First-Line Therapy According to Guidelines

The management of hypertension is guided by **NICE guidelines** (updated 2019), with therapy based on **age, ethnicity**, and the presence of **comorbidities**.

a) Lifestyle Modifications:

Dietary changes: Low-salt diet, high-fibre foods, and regular intake of fruits and vegetables.

Weight reduction: Aim for a **5-10% weight loss** in overweight patients.

Smoking cessation and reduction in **alcohol** and **caffeine** intake.

Exercise: Encourage regular physical activity (30 minutes of moderate exercise daily).

b) Pharmacological Therapy:

Step 1:

Patients < 55 years old: **ACE inhibitor (e.g., ramipril 2.5 mg once daily)** or **angiotensin receptor blocker (ARB)** if ACE inhibitors are not tolerated.

Patients ≥ 55 years or of African or Caribbean origin: **Calcium channel blocker (e.g., amlodipine 5 mg once daily)**.

Step 2:

ACE inhibitor/ARB + Calcium channel blocker (e.g., ramipril + amlodipine).

Step 3:

Add a **thiazide-like diuretic** (e.g., indapamide 1.5 mg once daily).

Step 4 (Resistant Hypertension):

Add **spironolactone** (if potassium < 4.5 mmol/L) or an **alpha-blocker** or **beta-blocker** (if potassium > 4.5 mmol/L).

Refer to a specialist if BP remains uncontrolled.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

ACE inhibitors: Contraindicated in **pregnancy** and patients with **bilateral renal artery stenosis** or **hyperkalaemia**.

Beta-blockers: Not recommended as first-line treatment in hypertensive patients unless there is a specific indication, such as **heart failure** or **post-myocardial infarction**.

b) Second-Line Therapy:

Angiotensin receptor blockers (ARBs): Used if **ACE inhibitors** cause a **persistent cough**.

Alpha-blockers: Can be used for resistant hypertension or in patients with **benign prostatic hyperplasia**.

Beta-blockers: Considered in younger patients or those with **ischaemic heart disease**.

8. Routine Monitoring and Follow-Up

Blood pressure monitoring: Every **4-6 weeks** until BP is controlled, then every **6-12 months**.

Renal function tests: Monitor **serum creatinine** and **electrolytes** regularly, especially if the patient is on ACE inhibitors or diuretics.

Cardiovascular risk factors: Regular checks for **diabetes** and **hyperlipidaemia** as part of ongoing management.

ECG and echocardiography: Repeat if there are concerns about **left ventricular function** or new cardiovascular symptoms.

9. Complications of Hypertension

Stroke: Chronic hypertension is a leading risk factor for **ischaemic** and **haemorrhagic strokes**.

Myocardial infarction: Increased risk of coronary artery disease.

Heart failure: Long-standing hypertension can lead to **left ventricular hypertrophy** and eventual heart failure.

Chronic kidney disease (CKD): Hypertension is both a cause and a consequence of CKD.

Hypertensive retinopathy: Chronic hypertension can lead to damage to the **retinal blood vessels**, causing vision problems.

Summary of Key Points for Essential and Secondary Hypertension

Hypertension is classified into **essential** and **secondary** forms, with **essential hypertension** accounting for 90-95% of cases.

Diagnosis is based on **blood pressure measurements** using **ABPM** or **HBPM**.

Management involves **lifestyle modifications** and **pharmacotherapy**, with the choice of drugs guided by **age**, **ethnicity**, and comorbidities.

First-line medications include **ACE inhibitors** for younger patients and **calcium channel blockers** for older or African/Caribbean patients.

Regular monitoring of **blood pressure**, **renal function**, and **cardiovascular risk factors** is essential for long-term management.

11. Evaluation of the Deteriorating Patient

1. Detailed Definition of a Deteriorating Patient

A **deteriorating patient** refers to an individual whose clinical condition is worsening, often indicated by abnormal physiological parameters. This could lead to severe complications or death if not identified and managed promptly. Recognising early signs of deterioration is critical in preventing cardiorespiratory arrest or multiple organ failure.

2. Common Presenting Complaints and Symptoms

Signs of deterioration are often subtle at first and may develop over time. Early recognition is crucial for effective intervention.

a) Respiratory Symptoms:

Tachypnoea (Respiratory rate > 20 breaths per minute) is an early marker of deterioration.

Dyspnoea (shortness of breath) or **hypoxia** (SpO₂ < 94%) may indicate respiratory compromise.

Cyanosis may occur in more severe cases.

b) Cardiovascular Symptoms:

Hypotension (Systolic BP < 90 mmHg or > 40 mmHg drop from baseline) may suggest shock.

Tachycardia (Heart rate > 100 bpm) or **bradycardia** (< 60 bpm) may indicate cardiovascular instability.

Chest pain could indicate myocardial ischaemia or infarction.

c) Neurological Symptoms:

Altered mental status such as confusion, agitation, or reduced consciousness (e.g., reduced Glasgow Coma Scale score).

Seizures or new-onset **focal neurological deficits**.

d) Renal Symptoms:

Oliguria (Urine output < 0.5 mL/kg/h) or **anuria** may indicate poor perfusion or acute kidney injury.

e) Gastrointestinal Symptoms:

Abdominal pain, nausea, or vomiting may suggest gastrointestinal pathology or metabolic derangement.

3. First-Line Investigations

a) Vital Signs Monitoring:

Respiratory rate: Early marker of deterioration.

Heart rate and blood pressure: Assesses cardiovascular stability.

Oxygen saturation (SpO₂): Identifies hypoxia requiring oxygen therapy.

Temperature: May indicate infection or sepsis.

b) Arterial Blood Gas (ABG):

Used to evaluate **oxygenation**, **ventilation**, and **acid-base status**. It helps to detect **hypoxia**, **hypercapnia**, or **metabolic acidosis**.

c) Full Blood Count (FBC):

Identifies **infection** (raised white cell count), **anaemia**, or other haematological abnormalities.

d) Electrolytes and Renal Function:

Check for **electrolyte imbalances** (e.g., potassium, sodium) and **renal impairment** (raised creatinine, urea).

e) Lactate Levels:

Elevated **lactate** is a marker of tissue hypoperfusion, often seen in **septic shock** or other states of hypoxia.

f) Electrocardiogram (ECG):

Detects **cardiac arrhythmias**, **ischaemia**, or **myocardial infarction**.

g) Chest X-ray:

Assesses **lung pathology** such as pneumonia, pulmonary oedema, or pneumothorax.

4. Explanation of Investigations

Arterial Blood Gas (ABG): Detects **respiratory failure**, **metabolic acidosis**, or **hypoxaemia**.

Lactate levels: Elevated in **shock states**, indicating poor tissue perfusion.

Full blood count: Helps identify **infection**, **bleeding**, or **inflammatory states**.

ECG: Essential to detect **cardiac arrhythmias** or myocardial injury that may contribute to deterioration.

5. Diagnostic Criteria for the Deteriorating Patient

Respiratory rate: > 20 breaths per minute or < 8 breaths per minute.

Oxygen saturation (SpO₂): < 94% on room air.

Heart rate: > 100 bpm or < 60 bpm.

Systolic blood pressure: < 90 mmHg or a drop > 40 mmHg from baseline.

Altered mental status: Confusion, drowsiness, or a drop in Glasgow Coma Scale (GCS) score.

Urine output: < 0.5 mL/kg/h.

Elevated lactate: > 2 mmol/L, indicating hypoperfusion.

6. First-Line Therapy According to Guidelines

The **ABCDE** approach is recommended for managing deteriorating patients:

a) Airway:

Assess airway patency: If obstructed, use airway manoeuvres (e.g., **chin lift**, **jaw thrust**), and consider airway adjuncts (e.g., **nasopharyngeal** or **oropharyngeal airway**).

Prepare for possible **intubation** if the airway is compromised.

b) Breathing:

Administer **high-flow oxygen** (e.g., **15 L/min via a non-rebreather mask**) if SpO₂ < 94%.

Consider **non-invasive ventilation** (e.g., CPAP, BiPAP) if the patient has respiratory failure.

Treat underlying causes, such as **pneumonia**, **pulmonary embolism**, or **pneumothorax**.

c) Circulation:

Insert **IV access** and administer **IV fluids** (e.g., 500 mL of normal saline over 15 minutes) for hypotension.

Consider **inotropic support** (e.g., **noradrenaline**) if the patient remains hypotensive despite fluid resuscitation.

Treat any identified arrhythmias or myocardial ischaemia (e.g., **aspirin**, **beta-blockers**, **nitroglycerine**).

d) Disability:

Assess **consciousness** using the **AVPU** or **GCS** scale.

Administer **glucose** if hypoglycaemia is suspected (e.g., **50 mL of 20% glucose IV**).

Monitor for signs of **seizures** or stroke and take appropriate action (e.g., **anticonvulsants**, **thrombolysis**).

e) Exposure:

Examine the patient fully for any signs of trauma, infection (e.g., rashes, cellulitis), or other abnormalities.

Ensure the patient is kept warm and manage the underlying cause of deterioration.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

High-flow oxygen should be used with caution in patients with **chronic obstructive pulmonary disease (COPD)**, as it may worsen hypercapnia.

IV fluids should be administered cautiously in patients with **heart failure** or **renal failure** to avoid fluid overload.

b) Second-Line Therapy:

Inotropic support (e.g., **noradrenaline**) may be required if fluid resuscitation fails to correct hypotension in shock.

Non-invasive ventilation (NIV): Use **CPAP** or **BiPAP** in respiratory failure due to conditions such as heart failure or COPD exacerbations.

8. Routine Monitoring and Follow-Up

Continuous monitoring of vital signs: Respiratory rate, oxygen saturation, heart rate, blood pressure, and temperature.

Repeat ABGs to monitor for correction of acidosis and improved oxygenation.

Fluid balance: Monitor **urine output** hourly in patients with acute kidney injury or sepsis.

Neurological monitoring: Regular assessment of **GCS** in patients with altered mental status.

9. Complications in the Deteriorating Patient

Cardiopulmonary arrest: Without early recognition and intervention, patients may progress to cardiac or respiratory arrest.

Acute kidney injury: Hypoperfusion may lead to **renal failure**.

Sepsis: Delayed recognition and treatment of sepsis can result in **multi-organ failure** and death.

Hypoxic brain injury: Prolonged hypoxia due to respiratory failure may lead to permanent neurological damage.

Summary of Key Points for the Evaluation of a Deteriorating Patient

Early recognition and intervention are critical to improving outcomes in the deteriorating patient.

Use the **ABCDE approach** for systematic evaluation and management.

Investigations such as **ABG**, **lactate**, and **ECG** help identify the underlying cause and guide treatment.

First-line therapy includes **airway management**, **oxygen supplementation**, **IV fluid resuscitation**, and treatment of the underlying cause (e.g., antibiotics for sepsis).

Continuous monitoring of vital signs and physiological parameters is essential to assess response to treatment and prevent further deterioration.

12. Heart Failure

1. Detailed Definition of Heart Failure

Heart failure is a clinical syndrome characterized by the heart's inability to pump sufficient blood to meet the body's metabolic needs. It is a result of structural or functional cardiac disorders that impair the filling of the ventricles (diastolic heart failure) or the ejection of blood from the heart (systolic heart failure). Heart failure can be classified as:

Heart failure with reduced ejection fraction (HFrEF): Ejection fraction < 40%.

Heart failure with preserved ejection fraction (HFpEF): Ejection fraction ≥ 50%.

2. Common Presenting Complaints and Symptoms

Patients with heart failure often present with a combination of **cardiac, respiratory, and systemic symptoms**:

a) Respiratory Symptoms:

Dyspnoea: Shortness of breath on exertion or at rest, commonly worsening at night (orthopnoea, paroxysmal nocturnal dyspnoea).

Cough: May be productive of frothy, pink sputum, especially in acute heart failure (pulmonary oedema).

b) Cardiovascular Symptoms:

Fatigue: Due to inadequate perfusion of tissues and organs.

Palpitations: Resulting from arrhythmias.

Chest pain: Often seen in heart failure due to coronary artery disease.

c) Fluid Retention Symptoms:

Peripheral oedema: Swelling of the lower limbs due to fluid accumulation.

Ascites: Abdominal swelling due to fluid buildup in the peritoneal cavity.

Elevated Jugular Venous Pressure (JVP): Reflecting elevated central venous pressure.

3. First-Line Investigations

According to **NICE guidelines**, first-line investigations to assess heart failure include:

a) N-terminal Pro-B-type Natriuretic Peptide (NT-proBNP):

High levels (> 2000 pg/mL) indicate a high probability of heart failure, and echocardiography should be arranged within 2 weeks.

Raised levels (400-2000 pg/mL) suggest heart failure but require further assessment.

b) Transthoracic Echocardiography:

Provides structural and functional information about the heart, including **left ventricular ejection fraction (LVEF)**.

Helps to distinguish between **HFrEF** and **HFpEF**.

c) Electrocardiogram (ECG):

Detects **arrhythmias**, **ischaemia**, or **left ventricular hypertrophy (LVH)**, which are common in heart failure.

d) Full Blood Count (FBC):

To rule out anaemia, which can exacerbate heart failure.

e) Urea and Electrolytes (U&Es):

Assess renal function and electrolyte disturbances, particularly **hyponatraemia** or **hyperkalaemia**.

f) Chest X-ray:

May show evidence of **pulmonary congestion**, **cardiomegaly**, or **pleural effusions**.

4. Explanation of Investigations

NT-proBNP: Released by the heart in response to **increased wall stress**. Higher levels correlate with worse prognosis and severity.

Echocardiography: Evaluates **cardiac structure** and **ejection fraction**, essential in differentiating types of heart failure.

ECG: Detects underlying **ischaemic heart disease** or arrhythmias.

Chest X-ray: Detects **pulmonary oedema** and **cardiomegaly**, indicating fluid overload and heart failure.

5. Diagnostic Criteria for Heart Failure

Diagnosis of heart failure requires:

Symptoms (e.g., dyspnoea, fatigue) and **signs** (e.g., elevated JVP, peripheral oedema).

Evidence of **cardiac dysfunction** on investigations, especially **echocardiography** (reduced ejection fraction or structural heart changes).

Elevated NT-proBNP levels: > 400 pg/mL.

6. First-Line Therapy According to Guidelines

Management of heart failure depends on whether the patient has **HFrEF** or **HFpEF**. According to **NICE guidelines (2018)**, the key treatments include:

a) Heart Failure with Reduced Ejection Fraction (HFrEF):

Angiotensin-Converting Enzyme (ACE) Inhibitors:

Ramipril (initial dose 2.5 mg once daily, titrated to 10 mg daily).

Mechanism: Reduces **afterload** and improves cardiac output by blocking the formation of angiotensin II.

Beta-Blockers:

Bisoprolol (initial dose 1.25 mg once daily, titrated to 10 mg daily).

Mechanism: Reduces heart rate and myocardial oxygen demand, improving systolic function.

Mineralocorticoid Receptor Antagonists (MRA):

Spirolactone (25-50 mg once daily).

Mechanism: Reduces fluid retention by inhibiting aldosterone action.

Sodium-Glucose Cotransporter-2 (SGLT-2) Inhibitors:

Dapagliflozin (10 mg once daily).

Mechanism: Reduces blood glucose levels and provides additional heart failure benefits by promoting **natriuresis** and reducing **cardiac workload**.

b) Heart Failure with Preserved Ejection Fraction (HFpEF):

Diuretics:

Furosemide (initial dose 20-40 mg once daily).

Mechanism: Helps manage symptoms of fluid overload (e.g., pulmonary oedema, peripheral oedema) by increasing urinary output.

Lifestyle Management:

Weight management, salt reduction, and regular physical activity are recommended to improve symptoms and outcomes.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

ACE Inhibitors:

Contraindicated in patients with **bilateral renal artery stenosis** or **pregnancy**.

Monitor for **hyperkalaemia** and **renal dysfunction**.

Beta-Blockers:

Contraindicated in **severe asthma** or **heart block**.

b) Second-Line Therapy:

Angiotensin Receptor Neprilysin Inhibitor (ARNI):

Sacubitril/Valsartan is recommended in patients with **HFrEF** who remain symptomatic despite optimal doses of an ACE inhibitor and beta-blocker.

Ivabradine:

Reduces heart rate in patients with **sinus rhythm** and a heart rate > 75 bpm who are still symptomatic on maximum tolerated beta-blocker dose.

8. Routine Monitoring and Follow-Up

Renal function and electrolytes should be monitored every **1-2 weeks** after starting or increasing the dose of **ACE inhibitors** or **diuretics**.

Blood pressure and **heart rate** should be checked regularly to ensure therapy is effective and well-tolerated.

NT-proBNP levels may be monitored periodically to assess response to treatment.

Regular **weight monitoring** to detect signs of fluid overload.

9. Complications of Heart Failure

Acute pulmonary oedema: Life-threatening complication of acute heart failure, characterized by severe breathlessness and frothy sputum production.

Arrhythmias: Patients with heart failure are at increased risk of atrial fibrillation and ventricular arrhythmias.

Renal impairment: Worsening renal function due to poor cardiac output and overuse of diuretics.

Cardiogenic shock: Severe reduction in cardiac output leading to end-organ failure.

Summary of Key Points for Heart Failure

Heart failure is characterized by symptoms such as **dyspnoea**, **fatigue**, and **fluid retention**, and is confirmed by **echocardiography** and elevated **NT-proBNP**.

HFrEF management includes **ACE inhibitors**, **beta-blockers**, and **MRAs**, while **diuretics** are used in both **HFrEF** and **HFpEF** for fluid overload.

Close monitoring of **renal function**, **blood pressure**, and **electrolytes** is essential to avoid complications from therapy.

Routine follow-up is critical to assess the patient's response to therapy and modify treatment as necessary.

13. Hypovolaemic Shock

1. Detailed Definition of Hypovolaemic Shock

Hypovolaemic shock is a life-threatening condition resulting from a significant loss of intravascular fluid volume, leading to decreased **tissue perfusion** and **organ dysfunction**. It occurs when there is a critical reduction in circulating blood volume, which impairs the heart's ability to pump blood effectively, causing reduced **cardiac output** and **oxygen delivery** to tissues.

It can be caused by:

Haemorrhage (trauma, gastrointestinal bleeding, surgery)

Non-haemorrhagic causes (vomiting, diarrhoea, burns, excessive diuresis)

2. Common Presenting Complaints and Symptoms

Patients in hypovolaemic shock typically present with signs and symptoms related to **poor perfusion** and **compensatory mechanisms** attempting to maintain circulation.

a) Cardiovascular Symptoms:

Tachycardia: A compensatory increase in heart rate to maintain cardiac output.

Hypotension: As fluid loss continues, blood pressure falls.

Weak, thready pulse: Reflects decreased stroke volume and reduced perfusion.

b) Respiratory Symptoms:

Tachypnoea: Increased respiratory rate due to acidosis or compensatory mechanisms.

c) Signs of Poor Perfusion:

Pale, cool, clammy skin: Due to vasoconstriction and redirection of blood flow to vital organs.

Delayed capillary refill (> 2 seconds): Indicates poor peripheral perfusion.

Reduced urine output (oliguria): Due to poor renal perfusion.

d) Neurological Symptoms:

Altered mental status: Confusion, agitation, or drowsiness due to hypoperfusion of the brain.

Lethargy or **unconsciousness** in severe cases.

3. First-Line Investigations

a) Full Blood Count (FBC):

Assesses **haemoglobin** levels to detect anaemia or blood loss.

Elevated **haematocrit** may indicate haemoconcentration in non-haemorrhagic shock.

b) Urea and Electrolytes (U&Es):

Monitors for **electrolyte imbalances** and **renal function**. Hypovolaemia can lead to acute kidney injury.

c) Blood Gas Analysis (Arterial/venous):

Identifies **metabolic acidosis**, which reflects poor perfusion and tissue oxygenation. **Lactate** levels are used to assess the severity of shock.

d) Coagulation Profile:

Prothrombin time (PT) and **activated partial thromboplastin time (APTT)** help assess coagulation status, especially in haemorrhagic shock.

e) Cross-match:

Essential in cases of haemorrhage to prepare for possible **blood transfusion**.

f) Ultrasound/Focused Assessment with Sonography in Trauma (FAST):

A rapid ultrasound examination to identify sources of internal bleeding, especially in trauma.

g) Central Venous Pressure (CVP) Measurement:

Assesses **fluid status** and guides fluid resuscitation.

4. Explanation of Investigations

Blood gas analysis and lactate: Elevated lactate indicates **tissue hypoxia** and is a marker of the severity of shock.

FAST ultrasound: Used to identify free fluid in the abdomen, indicating internal bleeding.

Full blood count: Identifies **anaemia** from haemorrhage or **haemoconcentration** in fluid loss.

5. Diagnostic Criteria for Hypovolaemic Shock

Stages of Hypovolaemic Shock (Based on Blood Loss Percentage):

Class I: < 15% blood loss (750 mL in a 70 kg adult) – Usually asymptomatic, slight tachycardia.

Class II: 15-30% blood loss (750-1500 mL) – Tachycardia, tachypnoea, mild hypotension.

Class III: 30-40% blood loss (1500-2000 mL) – Marked hypotension, tachycardia, confusion.

Class IV: > 40% blood loss (> 2000 mL) – Severe hypotension, tachycardia, altered consciousness, anuria.

6. First-Line Therapy According to Guidelines

The primary goal of managing hypovolaemic shock is **volume replacement** and **stabilisation of circulation**. **NICE guidelines** recommend the following approach:

a) Fluid Resuscitation:

Crystalloids (e.g., **0.9% saline** or **Ringer's lactate**): Used initially for **fluid replacement**. Start with **500 mL bolus** over 15 minutes and reassess.

Colloids (e.g., Gelofusine) may be used in some cases but have fallen out of favour due to risks of coagulopathy and renal dysfunction.

b) Blood Transfusion (for haemorrhagic shock):

Packed red blood cells should be given if there is significant blood loss. Start with **cross-matched blood** if available, or use **O-negative** in emergencies.

Fresh frozen plasma (FFP) and **platelets** may also be required to maintain clotting function.

c) Vasopressors (e.g., noradrenaline):

Only used if fluid resuscitation fails to maintain perfusion. They increase **vascular tone** and improve **blood pressure**, but must be used cautiously as they can worsen tissue perfusion if intravascular volume is inadequate.

d) Oxygen Therapy:

Administer **high-flow oxygen** (15 L/min via non-rebreather mask) to improve tissue oxygenation.

e) Treat Underlying Cause:

Stop bleeding: Apply direct pressure to wounds, use **tourniquets** if necessary, or perform **surgery** to control internal haemorrhage.

Antiemetics or **antidiarrhoeals** in cases of non-haemorrhagic fluid loss.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Excessive fluid administration in patients with **heart failure** can lead to fluid overload, pulmonary oedema, and worsening of the condition.

Colloids are contraindicated in patients with **renal dysfunction** and have been associated with higher risks of acute kidney injury.

b) Second-Line Therapy:

Vasopressors (e.g., **noradrenaline**): Used when fluid resuscitation fails, especially in patients with **cardiogenic** or **mixed shock**.

Inotropes (e.g., **dobutamine**): May be considered in patients with concurrent **cardiac dysfunction**.

8. Routine Monitoring and Follow-Up

Vital signs monitoring: Continuous monitoring of **blood pressure**, **heart rate**, **respiratory rate**, and **oxygen saturation**.

Urine output monitoring: To assess for **renal perfusion** and recovery of adequate circulation.

Repeat blood gases: To monitor **lactate levels** and guide resuscitation efforts.

Regular haemoglobin checks: Especially in patients receiving transfusions.

9. Complications of Hypovolaemic Shock

Acute kidney injury: Due to poor perfusion of the kidneys.

Multi-organ failure: Resulting from prolonged hypoperfusion to vital organs.

Cardiac arrest: Due to inadequate circulation and oxygen delivery to the heart.

Coagulopathy: Especially in massive haemorrhage, where dilutional coagulopathy or disseminated intravascular coagulation (DIC) can occur.

Hypothermia: Rapid fluid resuscitation, especially with cold fluids or in trauma, can exacerbate hypothermia.

Summary of Key Points for Hypovolaemic Shock

Hypovolaemic shock is caused by significant fluid loss, either from **haemorrhage** or **non-haemorrhagic causes** (e.g., vomiting, diarrhoea).

Fluid resuscitation with crystalloids is the first-line treatment, and **blood transfusion** is essential in cases of haemorrhagic shock.

Vasopressors are used only if fluid replacement fails, and oxygen therapy is necessary to maintain adequate tissue oxygenation.

Regular monitoring of vital signs, blood gases, and urine output is critical to guide treatment and avoid complications such as **acute kidney injury** or **multi-organ failure**.

14. Hypoxia

1. Detailed Definition of Hypoxia

Hypoxia refers to a state in which the body or a region of the body is deprived of adequate oxygen supply at the tissue level. It can result from a variety of causes, including respiratory failure, reduced oxygen-carrying capacity of the blood, or impaired circulation. If left untreated, hypoxia can lead to cell damage, organ dysfunction, and death.

Types of hypoxia include:

Hypoxic hypoxia: Inadequate oxygen in the blood (e.g., respiratory failure).

Anaemic hypoxia: Decreased oxygen-carrying capacity (e.g., anaemia).

Stagnant hypoxia: Impaired circulation (e.g., heart failure).

Histotoxic hypoxia: Cells unable to use oxygen (e.g., cyanide poisoning).

2. Common Presenting Complaints and Symptoms

Symptoms of hypoxia can vary depending on the severity and duration but generally include:

a) Respiratory Symptoms:

Dyspnoea: Shortness of breath, especially on exertion.

Tachypnoea: Rapid breathing as a compensatory mechanism.

b) Cardiovascular Symptoms:

Tachycardia: Increased heart rate to compensate for low oxygen levels.

Arrhythmias: In severe hypoxia, due to poor oxygenation of cardiac tissue.

c) Neurological Symptoms:

Confusion: Disorientation or agitation due to cerebral hypoxia.

Headache: Often a result of inadequate oxygen to the brain.

Cyanosis: Bluish discolouration of the skin, lips, and extremities due to low oxygen saturation.

d) Systemic Symptoms:

Fatigue: Generalised weakness and tiredness due to lack of oxygen to the tissues.

Altered mental status: Lethargy or, in severe cases, unconsciousness.

3. First-Line Investigations

The primary goal of investigating hypoxia is to assess oxygenation, underlying causes, and potential complications. First-line investigations as per **NICE guidelines** include:

a) Arterial Blood Gas (ABG) Analysis:

Provides a direct measure of **oxygen (PaO₂)**, **carbon dioxide (PaCO₂)**, and **acid-base balance (pH)**.

Hypoxia is defined as **PaO₂ < 8 kPa (60 mmHg)** on room air.

b) Pulse Oximetry:

SpO₂ < 94% indicates hypoxia. In critically ill patients, **SpO₂ < 90%** is a red flag.

Used for continuous non-invasive monitoring.

c) Chest X-ray:

Identifies causes of hypoxia such as **pneumonia**, **pulmonary oedema**, **pneumothorax**, or **pleural effusions**.

d) Full Blood Count (FBC):

Assesses **haemoglobin** levels to rule out anaemia, which may cause or exacerbate hypoxia.

e) Electrocardiogram (ECG):

Used to assess for **arrhythmias**, **ischaemia**, or **right heart strain** (e.g., in pulmonary embolism).

f) Echocardiography:

Assesses **cardiac function** and may detect heart failure or right ventricular strain in conditions like **pulmonary embolism**.

4. Explanation of Investigations

ABG analysis: A definitive tool to measure **arterial oxygen** and assess for **respiratory failure** (e.g., hypoxaemic or hypercapnic).

Pulse oximetry: A simple, non-invasive method to monitor **oxygen saturation** continuously.

Chest X-ray: Identifies pulmonary causes of hypoxia, such as **consolidation**, **effusion**, or **pneumothorax**.

5. Diagnostic Criteria for Hypoxia

Hypoxia is diagnosed based on **arterial oxygen levels** and **clinical signs**:

Mild hypoxia: PaO₂ 8.0-10.6 kPa (60-80 mmHg).

Moderate hypoxia: PaO₂ 5.3-7.9 kPa (40-60 mmHg).

Severe hypoxia: PaO₂ < 5.3 kPa (40 mmHg).

Clinical signs include:

Cyanosis (SpO₂ < 85%).

Tachycardia, **confusion**, and **dyspnoea**.

6. First-Line Therapy According to Guidelines

The treatment of hypoxia focuses on oxygen supplementation and addressing the underlying cause. **NICE guidelines** recommend:

a) Oxygen Therapy:

Administer **high-flow oxygen** (15 L/min via a non-rebreather mask) in critically ill patients.

Target SpO₂ of 94-98% for most patients.

Target SpO₂ of 88-92% in patients with **COPD** or other conditions at risk of hypercapnic respiratory failure.

b) Non-Invasive Ventilation (NIV):

Consider for patients with **type 2 respiratory failure** (e.g., COPD exacerbations with hypercapnia).

CPAP or **BiPAP** is often used to improve ventilation.

c) Invasive Ventilation:

If oxygenation cannot be maintained with NIV, or if the patient is unconscious or uncooperative, **intubation** and **mechanical ventilation** may be required.

d) Treatment of Underlying Cause:

Antibiotics for pneumonia.

Diuretics for pulmonary oedema.

Anticoagulation for pulmonary embolism.

Chest drain for pneumothorax.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

High-flow oxygen should be used cautiously in patients with **COPD** due to the risk of **CO₂ retention** and **hypercapnic respiratory failure**.

b) Second-Line Therapy:

Non-invasive ventilation (NIV): For patients with **hypercapnic respiratory failure**, such as those with COPD or obesity hypoventilation syndrome.

Intubation and mechanical ventilation: If NIV fails or in cases of severe hypoxia or respiratory failure requiring airway protection.

8. Routine Monitoring and Follow-Up

Continuous monitoring of **SpO₂** using pulse oximetry.

ABG analysis to monitor for improvements in oxygenation and to assess acid-base balance.

Electrolytes and renal function to monitor for complications related to treatment, especially if diuretics or invasive ventilation is used.

Daily chest X-rays in patients requiring mechanical ventilation to assess for complications such as pneumothorax.

9. Complications of Hypoxia

Cardiac arrhythmias: Prolonged hypoxia can cause arrhythmias such as **atrial fibrillation** or **ventricular tachycardia**.

Hypoxic brain injury: Severe or prolonged hypoxia can lead to irreversible brain damage.

Pulmonary hypertension: Chronic hypoxia can lead to pulmonary hypertension and right heart failure.

Multi-organ failure: In severe cases, lack of oxygen to vital organs can lead to **renal failure**, **hepatic dysfunction**, and **shock**.

Summary of Key Points for Hypoxia

Hypoxia is characterised by low tissue oxygenation and can be caused by respiratory, cardiovascular, or haematological problems.

ABG analysis and **pulse oximetry** are crucial tools for diagnosing and monitoring hypoxia.

Treatment involves **oxygen therapy**, **ventilatory support**, and addressing the **underlying cause** (e.g., infection, heart failure, pneumothorax).

Careful monitoring is essential to prevent complications such as **hypercapnia** in at-risk patients, and to ensure improvement in oxygenation and tissue perfusion.

15. Induction of Anaesthesia

1. Detailed Definition of Induction of Anaesthesia

Induction of anaesthesia refers to the process of transitioning a patient from a conscious state to an unconscious, anaesthetised state before surgery or a medical procedure. This phase is critical in ensuring patient comfort, amnesia, analgesia, and suppression of autonomic responses to surgical stimuli. Induction is usually achieved by administering a combination of intravenous and/or inhalational anaesthetic agents.

2. Common Presenting Complaints and Symptoms in Induction Reactions

During the induction of anaesthesia, patients may experience or display the following reactions:

a) Respiratory Symptoms:

Apnoea: Temporary cessation of breathing immediately following the administration of anaesthetic agents.

Airway obstruction: Due to muscle relaxation and loss of protective airway reflexes.

Bronchospasm: Sudden constriction of the airway, especially in patients with asthma or other respiratory conditions.

b) Cardiovascular Symptoms:

Hypotension: Drop in blood pressure due to the vasodilatory effects of anaesthetic agents.

Bradycardia: Decreased heart rate, particularly with some agents like propofol.

Tachycardia: Sometimes seen due to inadequate anaesthetic depth or surgical stimulation.

c) Neurological Symptoms:

Loss of consciousness: The intended effect, with complete amnesia of the procedure.

Involuntary movements: Such as muscle twitching or jerking, particularly with the use of some intravenous anaesthetic agents.

3. First-Line Investigations Prior to Induction

Prior to the induction of anaesthesia, a comprehensive pre-operative assessment is required to identify potential risks and underlying conditions. The following investigations are commonly performed:

a) Full Blood Count (FBC):

Assesses **haemoglobin** levels to ensure adequate oxygen-carrying capacity.

Platelet count is checked to rule out any bleeding tendencies.

b) Electrolyte Levels (U&Es):

Measures **sodium**, **potassium**, and other electrolytes to ensure metabolic stability before induction.

c) Coagulation Profile:

Prothrombin time (PT) and **activated partial thromboplastin time (APTT)** are evaluated in patients with bleeding disorders or on anticoagulants.

d) Electrocardiogram (ECG):

Evaluates heart rhythm and function, especially in patients with cardiac disease, to anticipate any potential arrhythmias during induction.

e) Chest X-ray (if indicated):

Performed in patients with known respiratory conditions or a history of smoking to check for **pulmonary pathology**.

4. Explanation of Investigations

FBC: Ensures that the patient has adequate **red cell mass** and no bleeding risks.

U&Es: Detects any electrolyte imbalances, which could be critical during anaesthesia (e.g., hypokalaemia or hyperkalaemia leading to arrhythmias).

ECG: Screens for **arrhythmias**, **ischaemia**, or **conduction defects** that may complicate induction.

5. Diagnostic Criteria and Assessment Before Induction

The decision to induce anaesthesia is based on the following assessments:

ASA Classification (American Society of Anesthesiologists Physical Status Classification):

ASA I: A normal healthy patient.

ASA II: A patient with mild systemic disease.

ASA III: A patient with severe systemic disease.

ASA IV: A patient with severe systemic disease that is a constant threat to life.

ASA V: A moribund patient who is not expected to survive without the operation.

Airway Assessment:

Mallampati classification: A scoring system used to predict the ease of endotracheal intubation.

Thyromental distance and **neck mobility** are assessed to anticipate any difficulty in securing the airway.

Vital signs:

Blood pressure, heart rate, and oxygen saturation are measured to establish a baseline before anaesthetic administration.

6. First-Line Therapy (Anaesthetic Agents)

The choice of agents for the induction of anaesthesia depends on the patient's clinical condition, the procedure, and the anaesthetic plan. Common first-line agents include:

a) Intravenous Anaesthetic Agents:

Propofol:

Dose: 1.5–2.5 mg/kg for adults.

Mechanism: Acts on GABA receptors to induce loss of consciousness.

Adverse effects: Hypotension, bradycardia, and apnoea are common.

Thiopental:

Dose: 3–5 mg/kg.

Mechanism: Barbiturate that enhances GABA activity, causing rapid loss of consciousness.

Adverse effects: Myocardial depression, hypotension, and respiratory depression.

Ketamine:

Dose: 1–2 mg/kg.

Mechanism: NMDA receptor antagonist that induces dissociative anaesthesia.

Adverse effects: Hypertension, tachycardia, and increased salivation. However, it preserves airway reflexes and is useful in patients with **asthma** or **hypovolaemia**.

b) Inhalational Anaesthetic Agents:

Sevoflurane:

Commonly used for inhalational induction, especially in **paediatrics** or **uncooperative patients**.

Mechanism: GABA receptor agonist leading to loss of consciousness.

Adverse effects: Can cause hypotension and respiratory depression.

Nitrous Oxide (N₂O):

Often used as a **supplement** to other anaesthetic agents due to its analgesic properties.

Adverse effects: Can cause nausea, vomiting, and diffusion hypoxia if not adequately oxygenated during emergence.

c) Muscle Relaxants (Facilitates Intubation):**Succinylcholine (Suxamethonium):**

Dose: 1–1.5 mg/kg.

Mechanism: Depolarising muscle relaxant that binds to acetylcholine receptors at the neuromuscular junction.

Adverse effects: Hyperkalaemia, malignant hyperthermia, and bradycardia.

Rocuronium:

Dose: 0.6–1 mg/kg.

Mechanism: Non-depolarising muscle relaxant that blocks acetylcholine receptors.

Adverse effects: Prolonged paralysis if higher doses are used.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:****Propofol:**

Contraindicated in patients with **egg allergy**.

Use with caution in patients with **hypotension** or **heart failure** due to its myocardial depressive effects.

Thiopental:

Contraindicated in patients with **porphyria**.

Succinylcholine:

Contraindicated in patients with **hyperkalaemia**, **burn injuries**, or a history of **malignant hyperthermia**.

b) Second-Line Therapy:**Etomidate:**

Dose: 0.3 mg/kg.

Mechanism: GABA receptor agonist with minimal cardiovascular effects, making it useful for patients with **haemodynamic instability**.

Adverse effects: Adrenal suppression.

Midazolam:

Dose: 0.1–0.3 mg/kg.

Used in cases where deeper sedation is needed prior to anaesthesia or in anxious patients.

8. Routine Monitoring and Follow-Up

Continuous monitoring of the patient's **vital signs**, including **heart rate**, **blood pressure**, **respiratory rate**, and **oxygen saturation**, throughout induction.

Capnography: Measures **end-tidal CO₂** to confirm correct placement of the endotracheal tube.

Neuromuscular monitoring: If muscle relaxants are used, monitors the depth of muscle relaxation and the degree of paralysis.

ECG monitoring: Continuous to detect arrhythmias during induction.

9. Complications of Induction of Anaesthesia

Airway obstruction: Due to loss of airway tone or inadequate ventilation.

Aspiration: If the patient has a full stomach or an unprotected airway, gastric contents can be aspirated into the lungs.

Haemodynamic instability: Hypotension or bradycardia due to the vasodilatory effects of anaesthetic agents.

Malignant hyperthermia: A rare but life-threatening condition triggered by **succinylcholine** or inhalational agents.

Summary of Key Points for Induction of Anaesthesia

Induction of anaesthesia involves transitioning a patient from consciousness to an anaesthetised state using **intravenous** or **inhalational** agents.

Pre-operative assessment is critical, including airway evaluation and risk stratification using the **ASA classification**.

Common agents include **propofol**, **thiopental**, and **sevoflurane**, with adjuncts such as **muscle relaxants** to facilitate intubation.

Monitoring throughout the induction phase is essential to avoid complications like **aspiration**, **hypotension**, or **airway obstruction**.

16. Ischaemic Heart Disease

1. Detailed Definition of Ischaemic Heart Disease (IHD)

Ischaemic Heart Disease (IHD), also known as **coronary artery disease (CAD)**, refers to a condition where there is a **reduction of blood supply to the heart muscle** due to narrowing or blockage of the coronary arteries. This is commonly caused by **atherosclerosis** and can lead to symptoms like angina and, in more severe cases, myocardial infarction (heart attack).

IHD can manifest as:

Stable Angina: Chest pain that occurs predictably with exertion and resolves with rest.

Unstable Angina: Chest pain that occurs unpredictably or at rest.

Myocardial Infarction: Complete blockage of a coronary artery causing death of the heart muscle.

2. Common Presenting Complaints and Symptoms

a) Chest Pain:

Central chest pain or discomfort, often described as **tightness, heaviness, or pressure**.

Can radiate to the **jaw, neck, back, or left arm**.

Stable angina: Occurs on exertion, relieved by rest or **glyceryl trinitrate (GTN)**.

Unstable angina: Occurs at rest or with minimal exertion, lasts longer, and is not relieved by GTN.

b) Associated Symptoms:

Dyspnoea: Shortness of breath, especially with exertion.

Palpitations: Awareness of abnormal or fast heartbeats.

Dizziness or light-headedness.

Fatigue: Especially during physical activity.

Sweating, nausea, and vomiting in acute cases (e.g., myocardial infarction).

3. First-Line Investigations

The main aim of investigations in IHD is to assess the extent of coronary artery disease, confirm the diagnosis, and stratify risk.

a) Electrocardiogram (ECG):

Resting ECG: Detects ischaemic changes like **ST-segment depression**, **T-wave inversion**, or **pathological Q waves** in myocardial infarction.

Stress ECG: Performed during exercise to detect ischaemic changes under exertion.

b) Blood Tests:

Troponin levels: Elevated in myocardial infarction due to heart muscle damage.

Lipid profile: To assess cholesterol levels as a risk factor for atherosclerosis.

Blood glucose/HbA1c: To detect diabetes, a significant risk factor for IHD.

Full Blood Count (FBC): To rule out anaemia, which can exacerbate ischaemic symptoms.

c) Coronary Angiography:

Gold standard investigation for diagnosing **coronary artery disease**. It visualises the coronary arteries and identifies blockages.

d) Cardiac Stress Test (Exercise Tolerance Test):

Assesses the heart's ability to function under stress and detect **exercise-induced ischaemia**.

e) Echocardiogram:

Assesses heart structure and function, detects wall motion abnormalities caused by ischaemia or infarction.

4. Explanation of Investigations

ECG: Shows **ischaemic changes** like ST depression or **pathological Q waves** in myocardial infarction.

Troponin: A highly specific marker of **myocardial injury**. Elevated troponin levels indicate heart muscle damage.

Coronary angiography: Direct visualisation of the coronary arteries, used to identify blockages requiring stenting or bypass surgery.

5. Diagnostic Criteria for Ischaemic Heart Disease

The diagnosis of IHD is based on a combination of clinical history, physical examination, and investigations.

Stable Angina:

Typical exertional chest pain relieved by rest or **GTN**.

Confirmed by **stress testing** or **angiography**.

Acute Coronary Syndrome (ACS):

Unstable Angina: Angina occurring at rest or with minimal exertion, lasting > 20 minutes.

Myocardial Infarction:

STEMI: ST-segment elevation on ECG with elevated troponins.

NSTEMI: Non-ST-segment elevation on ECG with elevated troponins.

NICE Guidelines recommend a combination of clinical assessment, ECG, and troponin levels for diagnosing acute coronary syndromes.

6. First-Line Therapy According to Guidelines

The management of IHD aims to relieve symptoms, prevent progression, and reduce the risk of major cardiovascular events such as myocardial infarction.

a) Lifestyle Modification:

Smoking cessation, weight loss, exercise, and a **Mediterranean diet** (rich in vegetables, fruits, whole grains, and olive oil).

b) Medical Therapy:

Antiplatelet Therapy:

Aspirin 75 mg once daily: Prevents platelet aggregation and reduces the risk of coronary thrombosis.

Clopidogrel (or other P2Y₁₂ inhibitors like ticagrelor) may be added in ACS or in patients who cannot tolerate aspirin.

Statins:

Atorvastatin 80 mg daily to lower cholesterol and stabilise atherosclerotic plaques.

Beta-Blockers:

Bisoprolol 5-10 mg daily: Reduces heart rate and myocardial oxygen demand, first-line for angina relief.

ACE Inhibitors (e.g., ramipril):

Reduces blood pressure, protects against further heart damage, particularly in patients with diabetes or heart failure.

Nitrates:

Glyceryl trinitrate (GTN): Relieves angina by dilating coronary vessels. Used sublingually for acute episodes.

Calcium Channel Blockers:

Amlodipine 5-10 mg daily, especially in patients who cannot tolerate beta-blockers.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Beta-blockers: Contraindicated in **asthma** or **severe bradycardia**.

Aspirin: Should be avoided in patients with active **peptic ulcer disease** or those with a known allergy to NSAIDs.

b) Second-Line Therapy:

Calcium channel blockers (e.g., diltiazem) can be used as alternatives to beta-blockers.

Long-acting nitrates (e.g., isosorbide mononitrate): Used for persistent angina when beta-blockers are contraindicated or insufficient.

Ivabradine: Used in patients with chronic stable angina who cannot tolerate beta-blockers or calcium channel blockers.

8. Routine Monitoring and Follow-Up

ECG monitoring for ongoing ischaemia or new arrhythmias.

Regular lipid profile and **renal function tests** to monitor the efficacy and safety of statins and ACE inhibitors.

Blood pressure and **heart rate** monitoring to ensure adequate control.

HbA1c and **blood glucose** monitoring in patients with diabetes.

9. Complications of Ischaemic Heart Disease

Myocardial infarction: Complete occlusion of a coronary artery leading to heart muscle death.

Heart failure: Due to chronic ischaemia or myocardial infarction resulting in reduced cardiac output.

Arrhythmias: Such as atrial fibrillation or ventricular tachycardia due to ischaemic damage to the heart's electrical system.

Sudden cardiac death: Due to ventricular fibrillation or severe myocardial infarction.

Left ventricular aneurysm: Following a large myocardial infarction.

Summary of Key Points for Ischaemic Heart Disease

Ischaemic Heart Disease (IHD) results from reduced blood flow to the heart due to **coronary artery narrowing** or blockage.

It presents as **stable angina**, **unstable angina**, or **myocardial infarction**.

Diagnosis involves **ECG**, **troponin measurement**, and **coronary angiography**.

Management includes **lifestyle changes**, **antiplatelet agents** (e.g., aspirin), **beta-blockers**, **statins**, and sometimes **nitrates** or **ACE inhibitors**.

Regular monitoring of **lipid profiles**, **ECG**, and **blood pressure** is important to prevent complications like **myocardial infarction** or **heart failure**.

17. Maintenance and Monitoring During Anaesthesia

1. Detailed Definition of Maintenance and Monitoring During Anaesthesia

Maintenance of anaesthesia refers to the phase following induction where the patient's unconscious state is sustained to allow a surgical or diagnostic procedure to continue. It involves using anaesthetic agents to maintain the desired depth of anaesthesia, provide analgesia, and prevent movement in response to surgical stimuli. This phase is managed through a combination of **inhalational agents**, **intravenous agents**, and **analgesics**.

Monitoring during anaesthesia involves continuous assessment of physiological parameters to ensure patient safety and detect any complications early. Monitoring includes **vital signs**, **depth of anaesthesia**, **oxygenation**, **ventilation**, and **haemodynamic status**.

2. Common Goals During Maintenance of Anaesthesia

The primary goals during the maintenance phase include:

Ensure unconsciousness: Maintain adequate depth of anaesthesia to prevent awareness.

Provide analgesia: Control pain both intraoperatively and postoperatively.

Prevent movement: Maintain muscle relaxation and immobility.

Support vital functions: Ensure stable cardiovascular and respiratory function.

Avoid side effects: Minimise risks of hypotension, bradycardia, and hypoventilation.

3. First-Line Investigations and Monitoring During Anaesthesia

According to **NICE guidelines** and the **Association of Anaesthetists of Great Britain and Ireland (AAGBI)**, essential monitoring tools during the maintenance of anaesthesia include:

a) Electrocardiogram (ECG):

Continuous ECG monitoring provides information on heart rate and rhythm, detecting arrhythmias, myocardial ischaemia, or electrolyte disturbances.

b) Pulse Oximetry:

Measures **oxygen saturation (SpO₂)**, ensuring adequate oxygenation. Hypoxia is detected early when SpO₂ falls below 94%.

c) Blood Pressure Monitoring:

Can be **non-invasive** (using a cuff) or **invasive** (arterial line) for real-time monitoring.

Ensures stable perfusion pressure, typically aiming for systolic BP > 90 mmHg.

d) Capnography:

Measures **end-tidal carbon dioxide (EtCO₂)** to assess ventilation. Normal values are 35-45 mmHg.

Key for monitoring mechanical ventilation and detecting **hypoventilation, hyperventilation**, or equipment malfunction.

e) Temperature Monitoring:

Prevents **hypothermia**, which can increase bleeding risk and cause arrhythmias.

Methods include **skin probes, oesophageal probes, or nasopharyngeal probes**.

f) Depth of Anaesthesia Monitoring:

Bispectral index (BIS) monitoring or **EEG-based devices** are used to assess the depth of anaesthesia.

A BIS value of **40-60** is usually targeted during surgery to ensure unconsciousness.

g) Neuromuscular Monitoring:

Train-of-four (TOF) monitoring assesses the degree of muscle relaxation when neuromuscular blockers are used.

Ensures adequate relaxation and helps guide the timing of additional doses or reversal.

h) Urine Output:

Monitoring via a urinary catheter is essential, particularly in prolonged surgeries or cases of significant blood loss, to assess renal perfusion and fluid status.

4. Explanation of Monitoring Investigations

ECG: Detects **arrhythmias** or **myocardial ischaemia** in real-time, crucial for early intervention.

Capnography: Reflects the effectiveness of ventilation and the patient's CO₂ levels, helping prevent **respiratory acidosis** or **hypercapnia**.

Pulse oximetry: Monitors oxygenation to prevent **hypoxia**, especially during airway management or surgical procedures with increased oxygen demand.

5. Diagnostic Criteria for Safe Anaesthesia Maintenance

The diagnosis of potential complications during anaesthesia is based on deviations from normal physiological parameters:

Hypoxia:

SpO₂ < 94%.

EtCO₂ significantly below or above the normal range (35-45 mmHg) indicates hypoventilation or hyperventilation.

Hypotension:

Systolic BP < 90 mmHg or a **drop in mean arterial pressure (MAP) > 30%** from baseline.

Arrhythmias:

Any deviations from normal sinus rhythm detected on ECG (e.g., atrial fibrillation, ventricular tachycardia).

Inadequate anaesthesia:

BIS score > 60 may indicate insufficient depth of anaesthesia, risking awareness.

6. First-Line Therapy and Anaesthetic Agents During Maintenance

Several classes of drugs are used to maintain anaesthesia during the procedure. The choice depends on the patient's condition, surgical needs, and duration of the procedure.

a) Inhalational Anaesthetics:

Sevoflurane:

Mechanism: GABA receptor agonist, causing unconsciousness and sedation.

Dose: Delivered via vaporisers, commonly used at concentrations of 1-2%.

Adverse effects: Hypotension, respiratory depression.

Isoflurane:

Mechanism: Similar to sevoflurane, used in longer procedures.

Adverse effects: Can increase heart rate and cause bronchospasm in some patients.

Desflurane:

Mechanism: Short-acting, ideal for rapid recovery after surgery.

Adverse effects: Can cause tachycardia and airway irritation, so used cautiously in patients with respiratory conditions.

b) Intravenous Anaesthetic Agents:

Propofol (continuous infusion):

Mechanism: Acts on GABA receptors.

Dose: Infusion rate 4-12 mg/kg/hr.

Adverse effects: Hypotension, respiratory depression.

Remifentanyl (used as analgesia):

Mechanism: Ultra-short-acting opioid, used to provide analgesia and suppress autonomic responses to surgery.

Adverse effects: Bradycardia, hypotension.

c) Muscle Relaxants:

Rocuronium or Vecuronium:

Used for muscle relaxation during surgery.

Dose: Bolus followed by continuous infusion based on the degree of muscle relaxation required.

d) Reversal Agents (for Neuromuscular Blockers):

Neostigmine + Glycopyrrolate:

Reverses non-depolarising neuromuscular blockers at the end of surgery.

Dose: Neostigmine 0.05 mg/kg, Glycopyrrolate 0.01 mg/kg.

Sugammadex:

A specific reversal agent for rocuronium or vecuronium. Rapidly reverses muscle relaxation.

Dose: Depends on the degree of blockade (e.g., 2-4 mg/kg).

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Inhalational agents:

Sevoflurane may not be suitable in patients with a history of **malignant hyperthermia**.

Desflurane is contraindicated in patients with **severe asthma** due to the risk of bronchospasm.

Propofol:

Avoid in patients with **egg or soy allergy**.

b) Second-Line Therapy:

Total Intravenous Anaesthesia (TIVA): For patients with contraindications to inhalational agents, TIVA using **propofol and remifentanyl** can be used.

Ketamine: Can be considered for patients with **hypotension** or when **haemodynamic stability** is required.

8. Routine Monitoring and Follow-Up

During anaesthesia, continuous monitoring of vital signs is critical to ensure patient safety:

ECG: Continuous monitoring for arrhythmias or ischaemia.

Pulse oximetry: Continuous SpO₂ monitoring to avoid hypoxia.

Capnography: To monitor end-tidal CO₂ levels and ventilation.

Neuromuscular monitoring: For the appropriate use and reversal of muscle relaxants.

Temperature: Ensure normothermia throughout the procedure to prevent hypothermia-related complications.

Postoperatively:

Monitor the patient in the **post-anaesthesia care unit (PACU)** for respiratory function, haemodynamic stability, and full recovery from neuromuscular blockade.

Pain control: Assessment and administration of analgesics as needed.

9. Complications of Maintenance of Anaesthesia

Hypotension: Caused by vasodilation and myocardial depression from anaesthetic agents.

Bradycardia: Often seen with opioids like remifentanyl or during vagal stimulation.

Airway complications: Hypoventilation, obstruction, or accidental extubation.

Hypothermia: From prolonged exposure in the operating theatre, increasing the risk of **postoperative infections**.

Awareness under anaesthesia: Rare but serious, detected via inadequate monitoring of anaesthetic depth (e.g., high BIS values).

Summary of Key Points for Maintenance and Monitoring During Anaesthesia

Maintenance of anaesthesia aims to keep the patient unconscious, analgesic, and immobile during surgery.

Inhalational agents (e.g., sevoflurane) or **intravenous agents (e.g., propofol)** are used for maintenance.

Continuous **monitoring** of ECG, capnography, blood pressure, oxygen saturation, and neuromuscular blockade is essential for patient safety.

Depth of anaesthesia is monitored using devices like **BIS**, and **neuromuscular blockade** is monitored using **train-of-four**.

Common complications include **hypotension**, **bradycardia**, and **airway obstruction**.

18. Multi-Organ Dysfunction Syndrome (MODS)

1. Detailed Definition of Multi-Organ Dysfunction Syndrome (MODS)

Multi-Organ Dysfunction Syndrome (MODS) is a severe, life-threatening condition in which multiple organ systems fail to function properly due to an overwhelming systemic response to illness or injury. MODS is typically a progression from **systemic inflammatory response syndrome (SIRS)**, often triggered by **sepsis**, trauma, or severe burns. MODS can affect critical

organs such as the **heart, lungs, liver, kidneys, gastrointestinal tract**, and **brain**, leading to a high mortality rate if not managed effectively.

2. Common Presenting Complaints and Symptoms

MODS typically develops in critically ill patients and involves a combination of systemic signs and symptoms related to the failure of two or more organ systems. Symptoms are dependent on the organs affected but may include:

a) Respiratory Failure:

Dyspnoea and **hypoxia**, often progressing to **acute respiratory distress syndrome (ARDS)**.

Hypoxaemia despite supplemental oxygen.

Tachypnoea (rapid breathing).

b) Cardiovascular Dysfunction:

Hypotension: Often resistant to fluid resuscitation.

Tachycardia: Increased heart rate as a compensatory mechanism.

Poor capillary refill and **cold extremities** due to poor perfusion.

c) Renal Dysfunction:

Oliguria (decreased urine output) or **anuria** (no urine output).

Increased creatinine and **blood urea nitrogen (BUN)** levels, indicating **acute kidney injury (AKI)**.

d) Hepatic Dysfunction:

Jaundice, elevated **liver enzymes** (ALT, AST).

Coagulopathy (due to impaired production of clotting factors by the liver).

e) Gastrointestinal Dysfunction:

Ileus: Decreased bowel motility.

Malabsorption, gastrointestinal bleeding.

f) Neurological Dysfunction:

Altered mental status, confusion, agitation, or **coma**.

Seizures in severe cases.

g) Haematological Dysfunction:

Thrombocytopenia, **disseminated intravascular coagulation (DIC)**.

Bleeding or **bruising** easily.

3. First-Line Investigations

The following investigations are essential to assess organ function, identify the underlying cause, and guide management:

a) Blood Tests:

Full Blood Count (FBC): To assess for infection (raised white cell count) and anaemia.

Urea & Electrolytes (U&E): To monitor renal function and electrolyte imbalance.

Liver Function Tests (LFTs): To assess hepatic function.

Arterial Blood Gas (ABG): To assess for respiratory failure and metabolic acidosis.

Coagulation Profile: To check for coagulopathies such as DIC.

b) Imaging:

Chest X-ray (CXR): To assess for pulmonary oedema or **acute respiratory distress syndrome (ARDS)**.

Ultrasound: To check for hepatosplenomegaly, renal dysfunction, or fluid accumulation.

c) Microbiological Tests:

Blood cultures, urine cultures, and sputum cultures to identify infectious causes such as **sepsis**.

d) Electrocardiogram (ECG):

To assess for cardiac arrhythmias or myocardial ischaemia.

e) Urine Output Monitoring:

A key marker of renal function, with oliguria (< 0.5 ml/kg/hr) or anuria indicating acute kidney injury.

4. Explanation of Investigations

ABG: Measures oxygenation, carbon dioxide levels, and acid-base status. In MODS, **metabolic acidosis** or **respiratory failure** is often seen.

FBC: Detects **leucocytosis** or **thrombocytopenia**, which may indicate sepsis or DIC.

LFTs: Raised **ALT**, **AST**, and **bilirubin** indicate liver dysfunction.

5. Diagnostic Criteria for Multi-Organ Dysfunction Syndrome (MODS)

The diagnosis of MODS is clinical and based on the presence of dysfunction in two or more organ systems. Common diagnostic criteria include:

Respiratory Dysfunction:

PaO₂/FiO₂ ratio < 200 (indicating ARDS).

Cardiovascular Dysfunction:

Persistent **hypotension** requiring vasopressor support (e.g., noradrenaline).

Renal Dysfunction:

Creatinine > 2 mg/dL or urine output < 0.5 mL/kg/h for more than 12 hours.

Hepatic Dysfunction:

Bilirubin > 2 mg/dL, or raised liver enzymes.

Neurological Dysfunction:

Glasgow Coma Scale (GCS) < 10 without sedation.

Haematological Dysfunction:

Platelet count < 100,000 or **evidence of DIC**.

NICE Guidelines recommend early recognition and management of organ dysfunction in critically ill patients, particularly in those with sepsis.

6. First-Line Therapy According to Guidelines

The management of MODS is largely supportive and aims to restore and maintain organ perfusion, manage the underlying cause (e.g., infection in sepsis), and prevent further organ damage.

a) Haemodynamic Support:**Fluid Resuscitation:**

Initial therapy with **crystalloids** (e.g., **0.9% saline** or **Ringer's lactate**) to maintain intravascular volume and ensure adequate perfusion.

Vasopressors:

Noradrenaline (norepinephrine) is the first-line vasopressor if hypotension persists despite fluid resuscitation.

Adrenaline or **dobutamine** may be used if there is poor cardiac output.

b) Respiratory Support:**Oxygen Therapy:**

Provide supplemental oxygen or **non-invasive ventilation** to maintain SpO₂ > 94%.

Mechanical Ventilation:

For patients with **ARDS** or severe hypoxia, mechanical ventilation with low tidal volumes may be necessary.

c) Renal Support:

In severe cases of renal failure, **renal replacement therapy (e.g., haemodialysis)** may be required.

d) Antibiotics and Source Control:

If sepsis is suspected, initiate **broad-spectrum antibiotics** (e.g., **piperacillin-tazobactam** or **meropenem**) early, tailored according to microbiological findings.

Surgical intervention may be necessary for infections like **peritonitis** or **abscesses**.

e) Blood Products:

In the case of DIC or thrombocytopenia, **platelet transfusion** or **fresh frozen plasma (FFP)** may be required.

f) Glucose Control:

Maintain blood glucose levels between **6-10 mmol/L** using **insulin** infusions if necessary to prevent complications from hyperglycaemia.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Excessive fluid resuscitation in patients with ARDS or cardiogenic shock, as it can worsen pulmonary oedema.

Beta-blockers should be avoided in patients with severe hypotension or shock.

b) Second-Line Therapy:

Corticosteroids (e.g., hydrocortisone) may be used in patients with septic shock who are unresponsive to fluid resuscitation and vasopressors.

Extracorporeal membrane oxygenation (ECMO): In patients with severe refractory ARDS, ECMO may be used to support oxygenation.

8. Routine Monitoring and Follow-Up

Patients with MODS require continuous monitoring in an intensive care setting:

Haemodynamic Monitoring: Including invasive blood pressure monitoring and cardiac output assessment.

ECG Monitoring: Continuous ECG to detect arrhythmias.

Arterial Line: To monitor arterial blood gases and blood pressure in real time.

Urine Output Monitoring: To assess kidney function and response to therapy.

Blood Tests: Regular monitoring of electrolytes, liver and renal function, coagulation profile, and full blood count.

Nutritional Support: Enteral feeding is preferred, with parenteral nutrition if enteral is not feasible.

9. Complications of Multi-Organ Dysfunction Syndrome

Septic shock: Persistent hypotension despite fluid resuscitation, leading to multi-organ failure.

Acute Respiratory Distress Syndrome (ARDS): Life-threatening respiratory failure.

Acute Kidney Injury (AKI): May require dialysis and increase the risk of mortality.

Coagulopathy and DIC: Uncontrolled bleeding due to impaired clotting factors.

Liver Failure: Leading to jaundice, hepatic encephalopathy, and coagulopathy.

Death: MODS has a high mortality rate, especially in elderly or immunocompromised patients.

Summary of Key Points for Multi-Organ Dysfunction Syndrome (MODS)

MODS is a critical condition involving dysfunction of multiple organ systems, typically due to severe infection (sepsis), trauma, or burns.

Symptoms include dyspnoea, hypotension, oliguria, jaundice, and altered mental status, depending on the organs affected.

Investigations include blood tests (FBC, LFTs, U&E), ABG, and imaging to assess the extent of organ failure.

Management involves fluid resuscitation, vasopressors (noradrenaline), mechanical ventilation, renal replacement therapy, and antibiotics for sepsis.

Close **monitoring** of haemodynamics, oxygenation, renal function, and liver function is crucial in critically ill patients.

19. Obstructive Shock

1. Detailed Definition of Obstructive Shock

Obstructive shock occurs when there is a physical obstruction in the circulatory system that prevents adequate blood flow and oxygen delivery to the tissues, leading to tissue hypoperfusion and organ dysfunction. Unlike other forms of shock (e.g., cardiogenic or hypovolaemic shock), obstructive shock is primarily caused by an impediment to blood flow in the circulatory system rather than a failure of the heart or a loss of circulating volume.

Common causes of obstructive shock include:

Pulmonary embolism (PE): A blood clot in the pulmonary arteries obstructs blood flow through the lungs, leading to right heart strain and shock.

Tension pneumothorax: Air trapped in the pleural space increases pressure on the heart and lungs, impeding venous return and cardiac output.

Cardiac tamponade: Accumulation of fluid in the pericardium compresses the heart, preventing it from filling properly and reducing cardiac output.

2. Common Presenting Complaints and Symptoms

Patients with obstructive shock typically present with symptoms of shock and signs related to the underlying cause. General symptoms include:

Hypotension: A hallmark of shock, caused by reduced cardiac output.

Tachycardia: A compensatory response to hypotension.

Cold, clammy skin: Due to poor perfusion.

Oliguria or anuria: Decreased urine output due to reduced renal perfusion.

Altered mental status: Due to cerebral hypoperfusion.

Cause-Specific Symptoms:

Pulmonary Embolism (PE):

Sudden onset **dyspnoea** (shortness of breath).

Pleuritic chest pain.

Hypoxaemia and **tachypnoea** (rapid breathing).

Jugular venous distension due to right heart strain.

Tension Pneumothorax:

Sudden onset **unilateral pleuritic chest pain.**

Severe respiratory distress.

Tracheal deviation towards the opposite side.

Absent breath sounds on the affected side.

Cardiac Tamponade:

Beck's triad: Hypotension, raised jugular venous pressure (JVP), and muffled heart sounds.

Pulsus paradoxus: An exaggerated drop in systolic blood pressure during inspiration.

3. First-Line Investigations

Investigations aim to identify the underlying cause of obstructive shock and guide management.

a) Pulmonary Embolism (PE):

CT Pulmonary Angiography (CTPA): The gold standard for diagnosing PE, showing the location and size of the embolus.

ECG: May show **sinus tachycardia, right heart strain, or S1Q3T3 pattern.**

D-dimer: Elevated in cases of PE, although non-specific.

Arterial Blood Gas (ABG): May show hypoxaemia and respiratory alkalosis.

b) Tension Pneumothorax:

Chest X-ray (CXR): Shows a collapsed lung, tracheal deviation, and hyperlucency (increased air space) on the affected side.

Clinical Diagnosis: Often diagnosed clinically based on symptoms, especially in emergency settings.

c) Cardiac Tamponade:

Echocardiogram: The gold standard for diagnosing tamponade, showing pericardial effusion and signs of cardiac compression (e.g., right atrial collapse).

ECG: May show low-voltage QRS complexes or **electrical alternans.**

Chest X-ray: May show an enlarged, globular-shaped heart due to pericardial effusion.

4. Explanation of Investigations

CTPA: Directly visualises a pulmonary embolus obstructing the pulmonary arteries.

Echocardiogram: Detects the accumulation of fluid around the heart in tamponade and evaluates cardiac function.

Chest X-ray: Essential for diagnosing pneumothorax, showing lung collapse and mediastinal shift.

5. Diagnostic Criteria for Obstructive Shock

Obstructive shock is diagnosed based on the clinical presentation of shock (hypotension, tachycardia, poor perfusion) along with evidence of an underlying obstructive cause. Specific diagnostic criteria include:

Pulmonary Embolism: Confirmed by **CT pulmonary angiography** showing a clot in the pulmonary arteries.

Tension Pneumothorax: Diagnosed clinically by symptoms (e.g., unilateral chest pain, tracheal deviation, absent breath sounds) and confirmed by **chest X-ray.**

Cardiac Tamponade: Diagnosed by **echocardiography** showing pericardial effusion and signs of heart compression.

6. First-Line Therapy According to Guidelines

The management of obstructive shock focuses on treating the underlying cause while supporting circulation and oxygenation.

a) Pulmonary Embolism:

Anticoagulation: Start **low-molecular-weight heparin (LMWH)** or **unfractionated heparin** immediately in suspected cases.

Dose: LMWH **1 mg/kg** subcutaneously twice daily.

Thrombolysis: Indicated in massive PE with haemodynamic instability.

Agents: **Alteplase** 10 mg bolus, followed by 90 mg infusion over 2 hours.

Oxygen therapy: To maintain SpO₂ > 94%.

Fluids: Careful fluid resuscitation to maintain blood pressure.

b) Tension Pneumothorax:

Immediate needle decompression: Insert a large-bore needle into the **2nd intercostal space** in the **midclavicular line** to relieve pressure.

Chest tube insertion: After decompression, insert a **chest drain** into the **5th intercostal space** in the **midaxillary line**.

c) Cardiac Tamponade:

Pericardiocentesis: Urgent drainage of pericardial fluid via a needle to relieve pressure on the heart.

Fluids: Intravenous fluids to maintain preload and support cardiac output until pericardiocentesis is performed.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Thrombolysis: Contraindicated in patients with recent major surgery, stroke, or active bleeding.

Excessive fluid resuscitation: In cases of cardiac tamponade, large volumes of fluid can worsen the situation by increasing pressure on the heart.

b) Second-Line Therapy:

Surgical embolectomy: May be necessary in massive PE if thrombolysis fails or is contraindicated.

Thoracic surgery: Required for **definitive treatment** of a recurrent pneumothorax or large air leak.

Surgical pericardial window: Performed if recurrent tamponade occurs after pericardiocentesis.

8. Routine Monitoring and Follow-Up

Patients with obstructive shock require close monitoring in an intensive care setting:

ECG monitoring: Continuous monitoring for arrhythmias and heart rate changes.

Pulse oximetry: To ensure adequate oxygenation.

Arterial blood pressure: Continuous monitoring, often through an arterial line, to track blood pressure and guide fluid and vasopressor therapy.

Serial imaging: Chest X-rays or echocardiograms to assess the resolution of pneumothorax or tamponade.

9. Complications of Obstructive Shock

If not treated promptly, obstructive shock can lead to:

Cardiac arrest: Due to prolonged hypoperfusion and organ failure.

Multiorgan failure: Resulting from sustained hypotension and poor tissue oxygenation.

Recurrent episodes: Such as recurrent pulmonary embolism or pneumothorax.

Respiratory failure: Particularly in cases of large pulmonary embolism or tension pneumothorax.

Summary of Key Points for Obstructive Shock

Obstructive shock is caused by a mechanical obstruction in the circulation, leading to reduced blood flow and organ perfusion.

Common causes include **pulmonary embolism**, **tension pneumothorax**, and **cardiac tamponade**.

Diagnosis is made based on clinical signs of shock and specific investigations such as **CT pulmonary angiography**, **echocardiography**, and **chest X-ray**.

Treatment involves addressing the underlying cause (e.g., thrombolysis for PE, needle decompression for pneumothorax) and supportive care to maintain circulation and oxygenation.

20. Post-Operative Nausea and Vomiting (PONV)

1. Detailed Definition of Post-Operative Nausea and Vomiting (PONV)

Post-Operative Nausea and Vomiting (PONV) refers to nausea and/or vomiting that occurs after surgery, usually within the first 24 hours post-operatively. It is a common complication of anaesthesia and surgery, affecting approximately 20-30% of all surgical patients, but the incidence can be as high as 80% in high-risk individuals. PONV is unpleasant for patients, can

prolong hospital stay, and may increase the risk of other complications such as **aspiration** or **dehydration**.

2. Common Presenting Complaints and Symptoms

Patients experiencing PONV typically present with the following:

a) Nausea:

A **subjective sensation of the urge to vomit** or queasiness.

Often reported within the first few hours post-surgery but can persist for up to 24 hours or more.

b) Vomiting:

Emesis or actual vomiting occurs, where the contents of the stomach are expelled through the mouth.

Retching (dry heaving) may also be present without the production of vomit.

c) Other associated symptoms:

Abdominal discomfort.

Dizziness or **lightheadedness**.

Fatigue or **malaise** due to fluid loss or electrolyte imbalances.

3. First-Line Investigations

PONV is generally a clinical diagnosis based on patient history and presentation. However, investigations may be necessary to rule out other causes of nausea and vomiting if symptoms are prolonged or severe. First-line investigations might include:

a) Serum Electrolytes:

To assess for electrolyte imbalances such as **hypokalaemia** or **hyponatraemia** caused by vomiting.

b) Blood Glucose Levels:

To rule out hyperglycaemia or hypoglycaemia as potential causes of nausea and vomiting.

c) Renal Function Tests:

To evaluate for dehydration or **acute kidney injury** (AKI) due to prolonged vomiting.

d) Imaging (if indicated):

Abdominal X-ray or **ultrasound** to rule out post-operative ileus or other gastrointestinal complications.

4. Explanation of Investigations

Serum Electrolytes: Prolonged vomiting can lead to significant fluid and electrolyte loss, particularly of potassium, sodium, and chloride, causing imbalances that need to be corrected.

Renal Function Tests: Ensure that the kidneys are functioning properly and that dehydration is not causing a secondary renal complication.

5. Diagnostic Criteria for Post-Operative Nausea and Vomiting (PONV)

PONV is diagnosed clinically based on the presence of nausea, vomiting, or retching within the first 24-48 hours post-operatively. The **Apfel Score** is a commonly used tool to assess the risk of PONV and helps guide prophylactic measures:

Risk factors in the Apfel Score:

Female gender.

Non-smoker.

History of PONV or motion sickness.

Use of postoperative opioids.

Each risk factor scores 1 point, and the higher the score (out of 4), the higher the risk of developing PONV:

0-1 points: Low risk (10-20%).

2 points: Moderate risk (30-40%).

3 points: High risk (50-60%).

4 points: Very high risk (up to 80%).

6. First-Line Therapy According to Guidelines

a) Prophylaxis:

To prevent PONV in patients identified as being at moderate-to-high risk, **NICE guidelines** recommend administering **prophylactic antiemetics** at the time of induction. The choice of antiemetic depends on patient factors and the type of surgery.

5-HT₃ Antagonists (e.g., **ondansetron**):

Dose: 4 mg IV.

Mechanism: Blocks serotonin receptors in the chemoreceptor trigger zone (CTZ) and gastrointestinal tract.

Dexamethasone:

Dose: 4-8 mg IV at induction.

Mechanism: Corticosteroid with anti-inflammatory and antiemetic properties.

Use: Effective in combination with other antiemetics.

Droperidol:

Dose: 0.625-1.25 mg IV.

Mechanism: Dopamine receptor antagonist in the CTZ.

Cyclizine:

Dose: 50 mg IV/IM.

Mechanism: Antihistamine with antiemetic properties via blockade of histamine and muscarinic receptors.

Metoclopramide:

Dose: 10 mg IV.

Mechanism: Dopamine antagonist that enhances gastrointestinal motility.

b) Treatment of Established PONV:

For patients who develop PONV post-operatively, the following treatments are recommended:

Ondansetron: 4 mg IV.

First-line treatment for established nausea and vomiting post-operatively.

Dexamethasone: 4 mg IV.

Can be added if symptoms persist after initial treatment.

Combination Therapy:

Using more than one antiemetic from different classes (e.g., **ondansetron + dexamethasone**) is more effective than single-agent therapy.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:**

Ondansetron: Use with caution in patients with **prolonged QT syndrome** due to the risk of arrhythmias.

Droperidol: Contraindicated in patients with a history of **extrapyramidal reactions** or **prolonged QT interval**.

Metoclopramide: Contraindicated in patients with a history of **epilepsy** or **gastrointestinal obstruction**.

b) Second-Line Therapy:

If PONV is refractory to first-line agents, second-line options include:

Aprepitant (NK1 receptor antagonist):

Dose: 40 mg orally preoperatively.

Often used in high-risk patients or as a rescue therapy.

Scopolamine patch:

A transdermal patch that can be applied preoperatively for longer-lasting antiemetic effects.

Commonly used in patients undergoing procedures that increase the risk of PONV (e.g., abdominal or ear surgery).

8. Routine Monitoring and Follow-Up

Monitoring during the post-operative period involves regular assessment of:

Nausea and Vomiting Episodes:

Frequency of vomiting and intensity of nausea using subjective scales (e.g., **Visual Analogue Scale for Nausea**).

Electrolyte Levels:

Monitor if vomiting is persistent or severe, with particular attention to **sodium, potassium, and chloride** levels.

Hydration Status:

Assess for signs of dehydration such as dry mucous membranes, poor skin turgor, and reduced urine output.

Ongoing Risk of Aspiration:

Especially in patients with ongoing vomiting or reduced consciousness.

9. Complications of Post-Operative Nausea and Vomiting

If not managed appropriately, PONV can lead to serious complications:

Aspiration Pneumonia:

Inhalation of gastric contents into the lungs, particularly in patients with compromised airway reflexes.

Dehydration and Electrolyte Imbalance:

Prolonged vomiting can lead to **hypokalaemia, hyponatraemia, and metabolic alkalosis**.

Delayed Recovery and Prolonged Hospital Stay:

Uncontrolled nausea and vomiting can delay mobilisation and oral intake, increasing the length of stay.

Surgical Wound Dehiscence:

Persistent retching and vomiting can increase intra-abdominal pressure, leading to wound dehiscence in abdominal surgeries.

Summary of Key Points for Post-Operative Nausea and Vomiting

PONV is a common and unpleasant complication of surgery and anaesthesia, often requiring prophylactic treatment in high-risk patients.

The **Apfel Score** helps stratify risk and guide prophylactic antiemetic therapy.

First-line treatment includes **ondansetron**, **dexamethasone**, and **droperidol**; combination therapy is often more effective.

Persistent PONV can lead to complications such as **aspiration**, **dehydration**, and **electrolyte imbalance**.

Regular monitoring of **nausea episodes**, **electrolytes**, and **hydration status** is essential to ensure patient safety post-operatively.

21. Respiratory Arrest

1. Detailed Definition of Respiratory Arrest

Respiratory arrest refers to the complete cessation of respiratory effort, resulting in an absence of effective breathing. It is a life-threatening condition that, without prompt intervention, leads to inadequate oxygenation and carbon dioxide removal. This condition can rapidly progress to hypoxia, hypercapnia, and cardiac arrest. Respiratory arrest may be the result of various causes, including trauma, drug overdose, airway obstruction, or severe respiratory conditions such as asthma or chronic obstructive pulmonary disease (COPD).

2. Common Presenting Complaints and Symptoms

Patients experiencing respiratory arrest typically present with the following:

a) **Apnea (Absence of Breathing):**

Complete lack of chest movement or breathing sounds.

b) **Cyanosis:**

Bluish discolouration of the skin, lips, or extremities due to severe hypoxia.

c) **Unconsciousness:**

Loss of consciousness occurs within minutes due to cerebral hypoxia.

d) **Bradycardia or Asystole:**

A slow heart rate (bradycardia) or absence of electrical activity in the heart (asystole) as oxygen levels drop.

e) **Hypotension:**

Low blood pressure often accompanies the absence of respiration as the circulation becomes compromised.

3. First-Line Investigations

Respiratory arrest is primarily a clinical diagnosis requiring immediate resuscitative efforts. However, the following investigations are conducted alongside or after stabilisation:

a) Arterial Blood Gas (ABG) Analysis:

Used to assess oxygen (PaO₂), carbon dioxide (PaCO₂), and pH levels to gauge respiratory failure.

b) Pulse Oximetry:

Measures oxygen saturation (SpO₂) to quickly assess oxygenation levels in the blood.

c) Electrocardiogram (ECG):

Used to assess cardiac rhythm and detect arrhythmias that may co-occur with respiratory arrest.

d) Chest X-ray:

May be performed after stabilisation to assess for structural causes such as pneumothorax or other thoracic pathologies.

e) Electrolyte Panel (U&Es):

Evaluates for electrolyte imbalances such as hyperkalemia that may exacerbate respiratory or cardiac arrest.

4. Explanation of Investigations

a) Arterial Blood Gas (ABG):

Measures the levels of oxygen and carbon dioxide in the blood as well as pH, reflecting the body's acid-base balance. In respiratory arrest, ABG will show severe hypoxemia and hypercapnia.

b) Pulse Oximetry:

Non-invasive measurement of the percentage of haemoglobin bound to oxygen (SpO₂). Low readings (<90%) indicate hypoxia.

c) Electrolyte Panel (U&Es):

Assesses levels of key electrolytes (e.g., sodium, potassium, bicarbonate) that are vital for maintaining heart and respiratory function. Imbalances such as hyperkalemia can contribute to cardiac arrest.

5. Diagnostic Criteria for Respiratory Arrest

Respiratory arrest is a clinical diagnosis confirmed by the absence of breathing (apnea), severe hypoxemia, and often unconsciousness. Diagnostic tests such as ABG can confirm the severity of respiratory failure:

PaO₂: <60 mmHg (8 kPa) indicates hypoxemia.

PaCO₂: >45 mmHg (6 kPa) indicates hypercapnia.

NICE guidelines: The **NICE Guidelines on Resuscitation (CG50)** recommend immediate recognition and intervention in cases of respiratory arrest, with diagnostic tests playing a secondary role to clinical management.

6. First-Line Therapy According to Guidelines

a) Immediate Interventions:

Basic Life Support (BLS): Open the airway (head tilt/chin lift), provide rescue breaths, and begin chest compressions if necessary.

Advanced Life Support (ALS):

Bag-Valve-Mask Ventilation: Administer 100% oxygen to restore oxygen levels.

Endotracheal Intubation: Secure the airway to facilitate mechanical ventilation and protect against aspiration.

b) Medications:

Oxygen: Administer 100% oxygen via bag-valve mask or mechanical ventilation.

Mechanical Ventilation: Tidal volumes of 6-8 mL/kg and a respiratory rate of 10-12 breaths per minute are typically used based on ABG results and patient response.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Pneumothorax: In the presence of a tension pneumothorax, positive-pressure ventilation can worsen the condition, requiring decompression (needle thoracostomy) first.

Inability to Secure the Airway: If endotracheal intubation fails, consider alternative methods.

b) Second-Line Therapy:

Cricothyrotomy:

Dose: Emergency procedure.

Mechanism of action: Creates an airway by puncturing the cricothyroid membrane when other methods fail.

8. Routine Monitoring and Follow-Up

Monitoring is crucial during and after the resolution of respiratory arrest:

a) Arterial Blood Gases (ABG):

Regular ABGs to monitor oxygenation, carbon dioxide levels, and acid-base balance.

b) Pulse Oximetry:

Continuous SpO₂ monitoring to ensure adequate oxygenation.

c) End-tidal CO₂ (ETCO₂):

Monitors the effectiveness of ventilation by measuring exhaled carbon dioxide.

d) **Cardiac Monitoring:**

Continuous ECG to detect arrhythmias or other complications post-resuscitation.

9. Complications of Respiratory Arrest

Without prompt management, respiratory arrest can lead to:

a) **Hypoxic Brain Injury:**

Due to prolonged oxygen deprivation, leading to long-term neurological deficits.

b) **Aspiration Pneumonia:**

Inhalation of gastric contents during resuscitation or if the airway is not protected.

c) **Cardiac Arrest:**

Untreated respiratory arrest will ultimately result in cardiac arrest.

Summary of Key Points for Respiratory Arrest

Respiratory arrest is a critical condition requiring immediate life-saving interventions.

Diagnosis is clinical, with investigations like ABGs and pulse oximetry confirming the severity.

First-line therapy focuses on airway management and oxygenation through mechanical ventilation.

Ongoing monitoring of oxygenation, ventilation, and cardiac function is essential after the acute phase.

Complications include hypoxic brain injury and aspiration, necessitating swift and appropriate management.

This guide follows the **NICE Resuscitation Guidelines (CG50)** and **Resuscitation Council UK** protocols for the management of respiratory arrest.

22. Respiratory Failure

1. Detailed Definition of Respiratory Failure

Respiratory failure occurs when the respiratory system is unable to maintain adequate gas exchange, resulting in either hypoxemia (low oxygen levels in the blood) or hypercapnia (high carbon dioxide levels). Respiratory failure can be classified into two types:

Type 1 (Hypoxemic Respiratory Failure): Characterised by low PaO₂ (<8 kPa or 60 mmHg) with normal or low PaCO₂. It is often due to diseases affecting the lungs' ability to oxygenate the blood, such as pneumonia, pulmonary oedema, or pulmonary embolism.

Type 2 (Hypercapnic Respiratory Failure): Characterised by high PaCO₂ (>6.5 kPa or 50 mmHg) due to inadequate alveolar ventilation. This may be caused by conditions that affect the muscles or nervous system, such as COPD, neuromuscular diseases, or sedative overdose.

2. Common Presenting Complaints and Symptoms

Patients with respiratory failure may present with the following:

a) **Dyspnoea (Shortness of Breath):**

A subjective feeling of breathlessness, often worsened with activity.

b) **Cyanosis:**

Blue discolouration of the lips or extremities, indicating hypoxemia.

c) **Tachypnoea:**

Increased respiratory rate as a compensatory mechanism to improve oxygenation.

d) **Confusion or Altered Mental State:**

Hypoxia or hypercapnia can affect brain function, leading to agitation, confusion, or drowsiness.

e) **Use of Accessory Muscles:**

Laboured breathing with the use of neck and chest muscles to assist in respiration.

f) **Fatigue:**

Respiratory muscles may tire due to the increased effort required for breathing, especially in chronic respiratory failure.

3. First-Line Investigations

The following investigations are essential to assess the cause and severity of respiratory failure:

a) **Arterial Blood Gas (ABG) Analysis:**

What it measures: PaO₂, PaCO₂, pH, and bicarbonate (HCO₃⁻) levels.

Purpose: Identifies hypoxemia and hypercapnia, assesses the severity of respiratory failure, and determines whether it is type 1 or type 2.

b) **Chest X-ray:**

What it examines: Assesses the lungs for signs of pneumonia, pulmonary oedema, or pneumothorax.

Purpose: Identifies structural lung abnormalities that may contribute to respiratory failure.

c) **Pulmonary Function Tests (PFTs):**

What it measures: Forced expiratory volume in 1 second (FEV₁), vital capacity (VC), and other lung function parameters.

Purpose: Helps differentiate between obstructive and restrictive lung diseases.

d) **Blood Tests (FBC, U&Es, CRP):**

What they measure: Full blood count (FBC), urea and electrolytes (U&Es), and C-reactive protein (CRP).

Purpose: Identifies anaemia, infection, or electrolyte imbalances that may exacerbate respiratory failure.

e) **ECG and Echocardiogram:**

What they examine: Electrical activity and function of the heart.

Purpose: Detects co-existing heart conditions, such as heart failure or arrhythmias, which can exacerbate respiratory failure.

4. Explanation of Investigations

a) **Arterial Blood Gas (ABG):**

Evaluates oxygen (PaO₂) and carbon dioxide (PaCO₂) levels in the blood, along with pH and bicarbonate (HCO₃⁻) levels to assess acid-base balance. It helps classify the type of respiratory failure and its severity.

b) **Chest X-ray:**

Provides imaging of the lungs and thoracic cavity, helping to identify causes such as infections (pneumonia), fluid overload (pulmonary oedema), or air leaks (pneumothorax).

c) **Pulmonary Function Tests (PFTs):**

Quantify lung capacity and airflow to distinguish between obstructive (e.g., COPD) and restrictive (e.g., pulmonary fibrosis) patterns of lung disease.

5. Diagnostic Criteria for Respiratory Failure

Respiratory failure is diagnosed based on ABG results:

Type 1 Respiratory Failure (Hypoxemic):

PaO₂: <8 kPa (60 mmHg)

PaCO₂: Normal or low (<6 kPa or 45 mmHg)

This indicates failure to oxygenate despite normal ventilation, typically caused by lung pathology.

Type 2 Respiratory Failure (Hypercapnic):

PaO₂: <8 kPa (60 mmHg)

PaCO₂: >6.5 kPa (50 mmHg)

This indicates hypoventilation, usually caused by impaired respiratory muscle function, airway obstruction, or central depression of respiration.

NICE guidelines for managing respiratory failure follow similar diagnostic criteria, with emphasis on ABG interpretation to guide treatment.

6. First-Line Therapy According to Guidelines

a) **Oxygen Therapy:**

Target oxygen saturation: 88-92% for patients with chronic hypercapnia (e.g., COPD), and >94% for others.

Mode: Administered via nasal cannula, face mask, or non-rebreather mask, depending on severity.

NICE Guidance: Recommends cautious oxygen therapy in COPD to avoid worsening hypercapnia.

b) Non-Invasive Ventilation (NIV):

Indication: Type 2 respiratory failure (e.g., COPD exacerbation) with hypercapnia.

Mechanism: Provides positive pressure ventilation via a face mask to support breathing and reduce the work of respiratory muscles.

Dosage: Pressure settings are individualised based on ABG results and patient response.

c) Mechanical Ventilation (if NIV fails or in severe cases):

Indication: Severe hypoxemia or hypercapnia unresponsive to non-invasive methods.

Mechanism: Intubation and mechanical support to control ventilation and oxygenation.

d) Bronchodilators (for COPD-related respiratory failure):

Salbutamol: 2.5-5 mg nebulised every 4 hours.

Mechanism: Beta-2 agonist that relaxes bronchial smooth muscle, improving airflow in obstructive lung diseases.

e) Corticosteroids (for COPD or asthma exacerbations):

Prednisolone: 30-40 mg orally once daily for 5-7 days.

Mechanism: Reduces airway inflammation and improves respiratory function.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Oxygen therapy in chronic hypercapnia: In patients with COPD, excessive oxygen can depress respiratory drive, leading to worsening hypercapnia and acidosis.

Non-invasive ventilation (NIV): Contraindicated in patients with altered mental status or inability to protect the airway.

b) Second-Line Therapy:

Invasive Mechanical Ventilation:

Indication: Respiratory failure unresponsive to NIV or in patients with altered consciousness.

Mechanism: Intubation and ventilatory support, allowing control over oxygenation and ventilation.

Dosage: Ventilator settings are based on ABG results and individual needs.

IV Antibiotics (if infection is suspected):

Amoxicillin-clavulanate: 1.2 g IV every 8 hours for pneumonia or other bacterial infections.

Mechanism: Kills bacteria responsible for respiratory infections that may be exacerbating respiratory failure.

8. Routine Monitoring and Follow-Up

a) Arterial Blood Gas (ABG) Monitoring:

Regular ABG checks to monitor oxygenation, carbon dioxide levels, and acid-base balance, especially during oxygen or ventilation therapy.

b) Pulse Oximetry:

Continuous monitoring of oxygen saturation (SpO₂) to ensure appropriate oxygen delivery.

c) Electrolyte Monitoring:

Frequent checks of potassium, sodium, and bicarbonate levels to manage electrolyte disturbances, especially in hypercapnic respiratory failure.

d) Chest X-rays:

To monitor the progression of lung pathology or detect complications such as pneumonia or pneumothorax.

9. Complications of Respiratory Failure

a) Hypoxic Brain Injury:

Prolonged oxygen deprivation can lead to irreversible brain damage.

b) Respiratory Acidosis:

In type 2 respiratory failure, hypercapnia can lead to respiratory acidosis, which may worsen organ function.

c) Cardiac Arrest:

Severe hypoxemia or hypercapnia can precipitate cardiac arrest, especially in acute respiratory failure.

d) Pulmonary Hypertension:

Chronic hypoxemia can lead to increased pressure in the pulmonary circulation, eventually causing right heart failure.

Summary of Key Points for Respiratory Failure

Respiratory failure is defined by the inability of the lungs to maintain adequate oxygenation or ventilation, classified as type 1 (hypoxemic) or type 2 (hypercapnic).

First-line therapy includes oxygen supplementation, non-invasive ventilation, and mechanical ventilation for severe cases.

Regular monitoring of ABG, oxygen saturation, and lung imaging is essential in managing respiratory failure.

Complications of untreated respiratory failure include hypoxic brain injury, respiratory acidosis, and cardiac arrest.

This guide is based on **NICE** guidelines and other UK-based protocols for managing respiratory failure in both acute and chronic settings.

23. Substance Misuse Disorder

1. Detailed Definition of Substance Misuse Disorder

Substance Misuse Disorder (SMD), also known as substance use disorder, refers to a condition where the recurrent use of drugs (legal or illegal) leads to clinically significant impairment or distress. This disorder encompasses both dependence and addiction, characterised by an inability to control the consumption of substances despite adverse consequences. Substance misuse can involve alcohol, prescription medications (e.g., opioids, benzodiazepines), and illicit drugs (e.g., heroin, cocaine). The disorder often leads to physical, psychological, and social harm, with a high risk of comorbid mental and physical health conditions.

2. Common Presenting Complaints and Symptoms

Patients with substance misuse disorder may present with the following symptoms:

a) **Physical Dependence:**

A state where the body has adapted to the presence of the drug, leading to tolerance and withdrawal symptoms if the substance is not taken.

b) **Psychological Dependence:**

A compulsive craving for the substance, often linked to emotional or psychological needs.

c) **Withdrawal Symptoms:**

Symptoms depend on the substance but may include anxiety, tremors, sweating, nausea, vomiting, seizures (for alcohol or benzodiazepines), and restlessness.

d) **Impaired Control:**

Inability to reduce or stop substance use despite knowing its harmful consequences.

e) **Social and Occupational Dysfunction:**

Problems at work, school, or in personal relationships due to substance use.

f) **Risky Behaviour:**

Engaging in dangerous activities while under the influence or to obtain the substance (e.g., needle sharing, driving while intoxicated).

3. First-Line Investigations

The diagnosis of substance misuse disorder is mainly clinical, based on history and symptoms. However, the following investigations may be used to assess the effects of substance misuse and guide management:

a) **Urine Drug Screening:**

What it measures: Detects the presence of illicit drugs or prescription medications.

Purpose: Confirms recent substance use and helps guide treatment.

b) **Blood Alcohol Levels** (if alcohol misuse is suspected):

What it measures: Measures the concentration of alcohol in the bloodstream.

Purpose: Determines the severity of alcohol intoxication or chronic misuse.

c) **Liver Function Tests (LFTs):**

What it measures: Assesses the health of the liver, including enzymes (ALT, AST), bilirubin, and albumin levels.

Purpose: Detects liver damage, commonly seen with alcohol or certain drug misuse.

d) **Full Blood Count (FBC):**

What it measures: Assesses red blood cells, white blood cells, and platelets.

Purpose: Identifies anaemia, infection, or other blood disorders that may result from chronic substance misuse.

e) **Electrolyte Panel (U&Es):**

What it measures: Levels of sodium, potassium, chloride, bicarbonate, and creatinine.

Purpose: Identifies electrolyte imbalances, dehydration, or kidney dysfunction secondary to substance misuse.

4. Explanation of Investigations

a) **Urine Drug Screening:**

Provides a snapshot of recent substance use, helping clinicians confirm or refute suspicions of misuse and aiding in treatment planning.

b) **Liver Function Tests (LFTs):**

Liver enzymes such as ALT and AST are often elevated in individuals with alcohol misuse or other hepatotoxic substance use, indicating liver damage.

c) **Electrolyte Panel (U&Es):**

Chronic drug or alcohol use can lead to dehydration or renal impairment, both of which will alter electrolyte and renal function test results.

5. Diagnostic Criteria for Substance Misuse Disorder

Substance misuse disorder is diagnosed using the **DSM-5 criteria**, which require the presence of at least two of the following symptoms within a 12-month period:

Using larger amounts or for longer than intended.

Inability to cut down or control use.

Spending a great deal of time obtaining, using, or recovering from substance use.

Craving or a strong desire to use.

Recurrent use resulting in failure to meet obligations at work, school, or home.

Continued use despite social or interpersonal problems.

Giving up important activities because of use.

Using in physically hazardous situations.

Continued use despite knowledge of physical or psychological problems caused by the substance.

Tolerance (needing more to achieve the same effect).

Withdrawal symptoms when not using the substance.

NICE guidelines recommend a comprehensive assessment, including these criteria, alongside an evaluation of the social, psychological, and physical impacts of substance misuse.

6. First-Line Therapy According to Guidelines

a) Psychosocial Interventions:

Cognitive Behavioural Therapy (CBT):

Helps patients recognise the triggers for substance use and develop coping strategies to prevent relapse.

Motivational Interviewing:

A client-centred counselling approach designed to enhance motivation to change by helping patients resolve ambivalence towards their substance use.

b) Pharmacological Therapy (depending on the substance):

Opioid Dependence:

Methadone: 20-30 mg orally once daily initially, then titrated according to patient response.

Mechanism: A long-acting opioid agonist that reduces withdrawal symptoms and cravings by stabilising opioid receptors.

Buprenorphine: 4-8 mg sublingually once daily.

Mechanism: A partial opioid agonist, which reduces cravings and withdrawal symptoms while having a lower risk of overdose compared to methadone.

Alcohol Dependence:

Chlordiazepoxide: For alcohol withdrawal syndrome, usually 10-30 mg every 6-8 hours, tapering over several days.

Mechanism: A benzodiazepine that prevents withdrawal symptoms by reducing the hyperactivity of the central nervous system.

Acamprosate: 666 mg orally three times a day.

Mechanism: Restores the balance between excitatory and inhibitory neurotransmission in the brain, reducing cravings in abstinent patients.

Nicotine Dependence:

Nicotine Replacement Therapy (NRT): Dosage depends on the form (patches, gum, inhalers).

Mechanism: Replaces the nicotine from cigarettes, reducing cravings and withdrawal symptoms.

Varenicline (Champix): 0.5 mg orally once daily for 3 days, then 1 mg twice daily.

Mechanism: A partial agonist of nicotine receptors, which reduces cravings and the pleasure associated with smoking.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Methadone: Avoid in patients with a prolonged QT interval or those on other QT-prolonging medications due to the risk of arrhythmias.

Buprenorphine: Avoid in patients with severe liver impairment due to potential accumulation of the drug.

b) Second-Line Therapy:

Naltrexone: For alcohol or opioid dependence.

Dose: 50 mg orally once daily.

Mechanism: An opioid antagonist that blocks the euphoric effects of alcohol and opioids, reducing cravings and preventing relapse.

Disulfiram: For alcohol dependence.

Dose: 200 mg orally once daily.

Mechanism: Inhibits the enzyme aldehyde dehydrogenase, causing unpleasant reactions (e.g., flushing, nausea) when alcohol is consumed, thus acting as a deterrent.

8. Routine Monitoring and Follow-Up

a) Liver Function Monitoring:

Regular liver function tests (LFTs) in patients receiving medications like methadone, buprenorphine, or naltrexone due to their potential hepatotoxicity.

b) Mental Health Monitoring:

Patients with substance misuse disorders often have comorbid mental health conditions, requiring regular assessment and appropriate referral for psychiatric support.

c) Regular Drug Screening:

Periodic urine or blood drug testing to monitor for relapse or use of non-prescribed substances.

9. Complications of Substance Misuse Disorder

a) Overdose:

Accidental overdose is a significant risk, especially with opioids, alcohol, and benzodiazepines, potentially leading to respiratory depression, coma, or death.

b) Infections:

Intravenous drug users are at risk of blood-borne infections such as hepatitis B, hepatitis C, and HIV.

c) Liver Disease:

Chronic alcohol misuse or certain drug misuse can lead to cirrhosis, liver failure, and hepatocellular carcinoma.

d) Psychiatric Disorders:

Increased risk of anxiety, depression, psychosis, and suicidal ideation.

Summary of Key Points for Substance Misuse Disorder

Substance misuse disorder involves the compulsive use of substances, leading to significant impairment and distress.

Diagnosis is clinical, based on DSM-5 criteria, with urine drug screening and liver function tests as supportive investigations.

First-line therapy includes psychosocial interventions (CBT, motivational interviewing) and pharmacotherapy tailored to the specific substance.

Routine monitoring of liver function, mental health, and potential relapse is essential to ensure safe and effective treatment.

This guide follows UK-based **NICE guidelines** and other clinical protocols for the management of substance misuse disorders across a range of substances.

24. Valvular Heart Disease

1. Detailed Definition of Valvular Heart Disease

Valvular heart disease (VHD) refers to any dysfunction or abnormality of one or more of the heart's four valves: the aortic, mitral, tricuspid, and pulmonary valves. These valves ensure unidirectional blood flow through the heart chambers and into the circulatory system. VHD can present as **stenosis** (narrowing of the valve, restricting blood flow) or **regurgitation** (incompetence of the valve, allowing blood to leak backward). The most commonly affected

valves are the **aortic** and **mitral valves**. The condition can be congenital or acquired due to infections (e.g., rheumatic fever, endocarditis), degenerative changes (e.g., calcification), or other causes.

2. Common Presenting Complaints and Symptoms

Valvular heart disease may present with a wide range of symptoms, which vary depending on the affected valve and the severity of the dysfunction:

a) Exertional Dyspnoea (Shortness of Breath):

A common early symptom, especially in mitral and aortic valve disease, due to increased pressure in the pulmonary circulation.

b) Fatigue:

Reduced cardiac output can lead to poor oxygen delivery to tissues, resulting in fatigue.

c) Chest Pain or Angina:

Common in aortic stenosis due to reduced coronary blood flow or increased myocardial oxygen demand.

d) Palpitations:

Patients may experience an irregular heartbeat, often due to atrial fibrillation secondary to mitral regurgitation or stenosis.

e) Syncope (Fainting):

Often seen in aortic stenosis, where a fixed cardiac output limits blood flow to the brain during exertion.

f) Peripheral Oedema:

Fluid retention due to right-sided heart failure, more common in tricuspid or advanced mitral valve disease.

3. First-Line Investigations

Several investigations are used to diagnose and assess the severity of valvular heart disease:

a) Transthoracic Echocardiogram (TTE):

What it measures: Assesses valve morphology, movement, blood flow, and pressures across valves.

Purpose: Gold-standard investigation for evaluating the type and severity of valvular lesions (stenosis, regurgitation).

b) Electrocardiogram (ECG):

What it measures: Assesses the electrical activity of the heart.

Purpose: May show signs of left or right ventricular hypertrophy, atrial enlargement, or arrhythmias such as atrial fibrillation.

c) Chest X-ray:

What it examines: Evaluates heart size and the presence of pulmonary congestion or oedema.

Purpose: Useful for detecting cardiomegaly or pulmonary congestion secondary to heart failure.

d) Blood Tests (FBC, BNP, U&Es):

What they measure: Full blood count (FBC), B-type natriuretic peptide (BNP), urea, and electrolytes.

Purpose: BNP is a marker of heart failure, while other blood tests help assess renal function and anaemia, which may exacerbate cardiac symptoms.

e) Cardiac MRI or CT Scan:

What it examines: Provides detailed images of the heart's structure and function.

Purpose: Used in complex cases to better assess valve anatomy, especially in preparation for surgery.

4. Explanation of Investigations

a) Transthoracic Echocardiogram (TTE):

Non-invasive ultrasound that provides real-time images of heart valves, allowing clinicians to assess the degree of stenosis (narrowing of the valve) or regurgitation (leakage through the valve) and its impact on heart function.

b) BNP (B-type Natriuretic Peptide):

BNP is released by the heart in response to increased ventricular pressure. Elevated levels suggest heart failure, which is often a complication of severe valvular heart disease.

5. Diagnostic Criteria for Valvular Heart Disease

Diagnosis is made through clinical examination (heart murmurs) and confirmed by imaging studies, primarily the echocardiogram.

Aortic Stenosis:

Valve Area: Severe stenosis is defined as a valve area $<1 \text{ cm}^2$.

Gradient: Peak pressure gradient $>40 \text{ mmHg}$ across the aortic valve indicates severe disease.

Mitral Regurgitation:

Regurgitant Volume: Severe regurgitation is defined by a regurgitant volume $>60 \text{ mL}$ per beat or an effective regurgitant orifice area (EROA) $>0.4 \text{ cm}^2$.

NICE Guidelines:

NICE recommends using echocardiography as the primary diagnostic tool for assessing valvular disease and classifies severity based on valve area, regurgitant volume, and gradients.

6. First-Line Therapy According to Guidelines

a) **Medical Management** (for symptom relief or delaying progression):

Aortic Stenosis:

Avoid vasodilators and diuretics in severe stenosis, as they can reduce preload, leading to hypotension.

Mitral Regurgitation:

ACE Inhibitors (e.g., Ramipril): 2.5-5 mg orally once daily.

Mechanism: Reduces afterload, decreasing the regurgitant volume and improving forward flow.

Beta-blockers (e.g., Bisoprolol): 2.5-5 mg orally once daily.

Mechanism: Slows the heart rate and improves ventricular filling, particularly in patients with atrial fibrillation.

Heart Failure Treatment (for patients with severe disease):

Diuretics (e.g., Furosemide): 20-40 mg orally or IV.

Mechanism: Reduces fluid overload and pulmonary congestion in heart failure secondary to valvular disease.

b) **Surgical/Interventional Therapy:**

Aortic Valve Replacement (AVR):

Indication: Severe symptomatic aortic stenosis or asymptomatic severe stenosis with reduced ejection fraction (<50%).

Mechanism: Replaces the dysfunctional valve with a mechanical or bioprosthetic valve, restoring normal blood flow.

Mitral Valve Repair/Replacement:

Indication: Severe mitral regurgitation with symptoms or reduced left ventricular function.

Mechanism: Either repair or replace the valve to prevent backward blood flow and reduce the risk of heart failure.

Transcatheter Aortic Valve Implantation (TAVI):

Indication: Suitable for patients with severe aortic stenosis who are at high risk for open-heart surgery.

Mechanism: Minimally invasive procedure to replace the aortic valve without open-heart surgery.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Surgery: Open-heart surgery may be contraindicated in patients with significant comorbidities or frailty.

TAVI: Not suitable for patients with contraindications to anticoagulation or anatomical factors that limit the success of the procedure.

b) Second-Line Therapy:

Balloon Valvuloplasty (for aortic stenosis):

Indication: Used as a palliative measure or bridge to surgery.

Mechanism: A balloon is inserted via catheter and inflated to widen the narrowed valve.

Percutaneous Mitral Valve Repair (MitraClip):

Indication: Suitable for high-risk patients with severe mitral regurgitation who are not candidates for surgery.

Mechanism: A device is used to clip the mitral valve leaflets together, reducing regurgitation.

8. Routine Monitoring and Follow-Up

a) Echocardiography:

Regular echocardiograms (annually or every 6 months in severe cases) to monitor disease progression and valve function.

b) BNP Levels:

Routine monitoring of BNP levels in patients with heart failure to assess the response to treatment and identify worsening heart failure.

c) Symptom Monitoring:

Regular assessments for worsening dyspnoea, chest pain, syncope, or signs of heart failure.

d) Anticoagulation:

For patients with valve replacements, regular INR checks are required for those on warfarin to prevent thromboembolism.

9. Complications of Valvular Heart Disease

a) Heart Failure:

Progressive worsening of ventricular function due to increased pressure and volume overload.

b) Atrial Fibrillation:

Common in mitral valve disease, especially mitral stenosis, increasing the risk of stroke.

c) Thromboembolism:

Increased risk of blood clots, especially in patients with mechanical valve replacements or atrial fibrillation.

d) Endocarditis:

Infection of the heart valves, particularly in those with prosthetic valves or predisposing conditions such as congenital heart disease.

Summary of Key Points for Valvular Heart Disease

Valvular heart disease can present as stenosis or regurgitation of the heart valves, most commonly affecting the aortic and mitral valves.

Diagnosis relies on echocardiography, which provides essential information about valve function and the severity of disease.

Medical management focuses on relieving symptoms and delaying disease progression, while surgical interventions (e.g., valve replacement) are required for severe disease.

Regular monitoring through echocardiography, BNP levels, and symptom assessment is critical in managing valvular heart disease.

This guide follows UK-based **NICE guidelines** and other expert consensus on managing valvular heart disease, offering a comprehensive approach to diagnosis and treatment.

25. Ventricular Tachycardia (VT)

1. Detailed Definition of Ventricular Tachycardia

Ventricular tachycardia (VT) is a type of arrhythmia characterised by a rapid heart rate (over 100 beats per minute) that originates from abnormal electrical activity within the ventricles. VT can be classified into two main types:

Sustained VT: Lasts more than 30 seconds or requires intervention due to hemodynamic instability.

Non-sustained VT: Self-terminating episodes lasting less than 30 seconds.

VT can be **monomorphic** (regular QRS complexes) or **polymorphic** (irregular QRS complexes). It is a potentially life-threatening condition because it can lead to **ventricular fibrillation** and sudden cardiac death if not treated promptly. Causes include myocardial infarction, heart failure, and electrolyte disturbances.

2. Common Presenting Complaints and Symptoms

Patients with ventricular tachycardia may present with a range of symptoms, depending on the duration and rate of the arrhythmia:

a) **Palpitations:**

A sensation of a rapid or irregular heartbeat, often described as "pounding" or "fluttering."

b) **Chest Pain or Discomfort:**

Commonly reported due to reduced coronary perfusion during episodes of VT, especially in those with underlying coronary artery disease.

c) **Shortness of Breath (Dyspnoea):**

Patients may experience difficulty breathing due to decreased cardiac output.

d) **Dizziness or Lightheadedness:**

Inadequate cerebral perfusion due to reduced cardiac output can lead to dizziness or near-fainting.

e) **Syncope (Fainting):**

Loss of consciousness may occur in prolonged or severe VT due to significant hemodynamic compromise.

f) **Signs of Shock:**

In cases of severe VT, patients may present with hypotension, confusion, cold extremities, and signs of poor organ perfusion.

3. First-Line Investigations

The diagnosis of VT is primarily clinical, confirmed by ECG. Additional investigations are performed to assess the underlying cause and the impact of the arrhythmia:

a) **12-Lead Electrocardiogram (ECG):**

What it measures: Electrical activity of the heart, identifying rhythm, rate, and the morphology of QRS complexes.

Purpose: Diagnostic for VT, showing broad QRS complexes (>120 ms), a regular rhythm, and a ventricular rate >100 beats per minute.

b) **Electrolyte Panel (U&Es):**

What it measures: Levels of sodium, potassium, calcium, and magnesium.

Purpose: Detects electrolyte imbalances (e.g., hypokalemia, hypomagnesemia) that can precipitate VT.

c) **Cardiac Biomarkers (Troponins):**

What it measures: Troponin levels in the blood.

Purpose: Assesses for myocardial infarction, which can trigger VT.

d) **Echocardiogram:**

What it examines: Structural and functional aspects of the heart, including ejection fraction.

Purpose: Identifies underlying cardiac abnormalities, such as heart failure or valvular disease.

e) **Coronary Angiography (if ischemia is suspected):**

What it examines: Coronary artery patency.

Purpose: Identifies coronary artery disease as a precipitant of VT.

4. Explanation of Investigations

a) **12-Lead ECG:**

Shows a wide QRS complex tachycardia, which is the hallmark of VT. Differentiating between VT and supraventricular tachycardia with aberrancy is crucial, and ECG criteria like **capture beats** and **fusion beats** help in diagnosing VT.

b) Electrolyte Panel:

Abnormalities in potassium and magnesium levels can trigger or worsen VT. Correcting these imbalances is an important aspect of treatment.

c) Cardiac Biomarkers:

Elevated troponins suggest myocardial injury, which can trigger VT, particularly in the setting of an acute coronary syndrome.

5. Diagnostic Criteria for Ventricular Tachycardia

The diagnosis of VT is made based on ECG findings:

QRS Duration: >120 ms.

Ventricular Rate: >100 beats per minute.

Regular Rhythm: A consistent ventricular rhythm is more suggestive of monomorphic VT.

Morphology: In monomorphic VT, all QRS complexes appear similar, whereas polymorphic VT (e.g., torsades de pointes) shows variable QRS morphology.

NICE guidelines recommend immediate intervention based on clinical stability rather than waiting for further diagnostic confirmation in cases of VT.

6. First-Line Therapy According to Guidelines

a) Acute Management of VT:

Stable VT (Hemodynamically stable):

Intravenous Amiodarone: 300 mg IV over 20-60 minutes, followed by 900 mg over 24 hours.

Mechanism: A class III antiarrhythmic that prolongs repolarisation and stabilises cardiac electrical activity.

Intravenous Lidocaine: 1-1.5 mg/kg IV bolus, followed by 1-4 mg/min infusion (alternative to amiodarone).

Mechanism: A class Ib antiarrhythmic that blocks sodium channels, stabilising the heart's electrical activity.

Unstable VT (Hemodynamically unstable):

Immediate DC Cardioversion: Deliver synchronised shocks to restore normal rhythm.

Mechanism: Uses electrical energy to reset the abnormal electrical activity and restore sinus rhythm.

b) Long-Term Management:

Beta-Blockers (e.g., Bisoprolol): 2.5-5 mg orally once daily.

Mechanism: Reduces the heart's workload and controls heart rate by blocking beta-adrenergic receptors.

Implantable Cardioverter Defibrillator (ICD):

Indication: Recommended for patients with recurrent VT or those at high risk of sudden cardiac death.

Mechanism: Monitors heart rhythm and delivers an electric shock to terminate life-threatening arrhythmias.

Catheter Ablation:

Indication: For recurrent VT or patients not responding to medical therapy.

Mechanism: Destroys the abnormal areas of the myocardium responsible for initiating VT.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Amiodarone: Avoid in patients with severe liver disease, thyroid dysfunction, or pulmonary fibrosis, as it can exacerbate these conditions.

Lidocaine: Contraindicated in patients with severe heart block without a pacemaker.

b) Second-Line Therapy:

Sotalol: 80 mg orally twice daily.

Mechanism: A class III antiarrhythmic that prolongs the QT interval and helps prevent recurrent VT.

Magnesium Sulfate: Particularly useful for polymorphic VT (torsades de pointes), given as 2 g IV over 10-15 minutes.

Mechanism: Reduces early after-depolarisations and stabilises myocardial electrical activity.

8. Routine Monitoring and Follow-Up

a) Electrolyte Monitoring:

Regular assessment of potassium and magnesium levels, especially in patients on diuretics or those with a history of electrolyte disturbances.

b) ECG Monitoring:

Continuous ECG monitoring during acute episodes and regular 12-lead ECGs during follow-up to assess for recurrent arrhythmias.

c) ICD Checkups:

Patients with an ICD require regular device checks to ensure proper function and battery life.

d) Echocardiography:

Periodic echocardiograms to monitor heart function, especially if structural heart disease is present.

9. Complications of Ventricular Tachycardia

a) **Ventricular Fibrillation:**

VT can degenerate into ventricular fibrillation (VF), a life-threatening arrhythmia that leads to cardiac arrest if not treated immediately.

b) **Heart Failure:**

Prolonged or recurrent VT can lead to worsening of left ventricular function and heart failure.

c) **Sudden Cardiac Death:**

If left untreated, VT can result in sudden cardiac death, particularly in high-risk patients with underlying structural heart disease.

Summary of Key Points for Ventricular Tachycardia

Ventricular tachycardia is a potentially life-threatening arrhythmia that originates in the ventricles and requires prompt diagnosis and treatment.

The 12-lead ECG is diagnostic, showing wide QRS complexes and a rapid ventricular rate.

First-line therapy depends on the hemodynamic stability of the patient, with options including antiarrhythmic drugs (e.g., amiodarone) or immediate electrical cardioversion.

Long-term management involves beta-blockers, ICD implantation, and, in some cases, catheter ablation.

Close monitoring of electrolyte levels, cardiac function, and arrhythmia recurrence is crucial in preventing complications such as ventricular fibrillation or sudden cardiac death.

Breast disease

26. Breast Abscess and Mastitis

1. Detailed Definition of Breast Abscess and Mastitis

Mastitis: Mastitis is inflammation of the breast tissue, which can be associated with infection or milk stasis, most commonly occurring in lactating women. It presents as pain, redness, and swelling of the breast. If untreated, it can progress to a **breast abscess**, which is a localised collection of pus within the breast tissue.

Breast Abscess: A breast abscess is a complication of mastitis where a pus-filled cavity forms within the breast due to bacterial infection, commonly caused by *Staphylococcus aureus*. It presents with more pronounced pain, swelling, and often a fluctuant mass that may require drainage.

2. Common Presenting Complaints and Symptoms

Patients with **mastitis** typically present with the following:

a) **Breast Pain:**

Localized, tender pain in one or both breasts, often accompanied by warmth and redness.

b) **Erythema and Swelling:**

Redness and swelling in a segment of the breast, often wedge-shaped in lactational mastitis.

c) **Fever and Malaise:**

Systemic symptoms such as fever, chills, and general fatigue.

d) **Breast Engorgement:**

Often associated with breastfeeding, the breast may become overfilled with milk, contributing to inflammation and infection.

e) **Nipple Discharge:**

Possible purulent or blood-stained discharge from the nipple in some cases of infection.

For **breast abscess**, symptoms are similar but more severe and include:

f) **Fluctuant Mass:**

A painful, soft, palpable lump in the breast that indicates pus collection.

g) **Skin Changes:**

Overlying skin may appear shiny, taut, or thin, with signs of necrosis if left untreated.

3. First-Line Investigations

Mastitis is often diagnosed clinically, but investigations are warranted if an abscess or other complications are suspected:

a) **Breast Ultrasound:**

What it measures: Visualises breast tissue, identifying fluid collections (abscesses) or areas of inflammation.

Purpose: Helps differentiate between mastitis and abscess formation. It can also guide abscess drainage.

b) **Breast Milk Culture (if breastfeeding):**

What it measures: Identifies bacterial pathogens in breast milk.

Purpose: Confirms infection and guides antibiotic therapy, especially in recurrent or severe cases.

c) **Full Blood Count (FBC):**

What it measures: Assesses white blood cell count (WBC).

Purpose: Elevated WBC may indicate infection.

d) **C-Reactive Protein (CRP):**

What it measures: Measures levels of inflammation in the body.

Purpose: Elevated CRP can indicate the presence of infection or inflammation.

e) **Aspiration of Abscess (if abscess is present):**

What it examines: Pus is aspirated and sent for microbiological analysis.

Purpose: Identifies the causative organism and determines antibiotic sensitivity.

4. Explanation of Investigations

a) **Breast Ultrasound:**

Non-invasive imaging that identifies fluid-filled abscesses and helps guide needle aspiration or drainage procedures.

b) **Breast Milk Culture:**

Detects bacterial pathogens, such as *Staphylococcus aureus*, and provides antibiotic sensitivities to tailor treatment.

c) **Aspiration:**

Used for diagnostic confirmation and therapeutic drainage of pus. Culture of aspirated material guides antibiotic therapy.

5. Diagnostic Criteria for Breast Abscess/Mastitis

Mastitis is diagnosed clinically based on symptoms such as breast pain, redness, swelling, and systemic symptoms like fever.

Breast Abscess is confirmed via **breast ultrasound** showing a fluid-filled collection and may be accompanied by systemic signs of infection.

According to **NICE guidelines**, breast abscesses should be managed with drainage (needle aspiration or incision) and appropriate antibiotic therapy.

6. First-Line Therapy According to Guidelines

a) **Mastitis Treatment:**

Conservative Management:

Frequent Breastfeeding or Milk Expression: Helps relieve engorgement and prevent milk stasis, which can worsen mastitis.

Breast Massage and Warm Compresses: Facilitates milk flow and reduces discomfort.

Antibiotic Therapy (for suspected or confirmed infection):

Flucloxacillin: 500 mg orally four times daily for 10-14 days (first-line for *Staphylococcus aureus* infection).

Mechanism: A penicillin-class antibiotic that targets bacterial cell walls, leading to bacterial lysis.

Erythromycin or Clarithromycin (if penicillin-allergic):

Dose: Clarithromycin 500 mg orally twice daily for 7-14 days.

Mechanism: Macrolide antibiotics inhibit bacterial protein synthesis, effective against common pathogens such as *Staphylococcus aureus*.

b) Breast Abscess Treatment:

Needle Aspiration (preferred first-line treatment):

Mechanism: Aspiration with ultrasound guidance drains the abscess and is repeated if necessary. Minimally invasive and often allows for quicker recovery than incision.

Incision and Drainage (for larger or recurrent abscesses):

Mechanism: Surgical incision is made to drain the abscess cavity, followed by wound care and packing to promote healing.

Antibiotic Therapy:

Flucloxacillin: Same as for mastitis (500 mg four times daily).

Metronidazole: 400 mg orally three times daily if anaerobic bacteria are suspected, such as in recurrent or complex abscesses.

Mechanism: Effective against anaerobic bacteria by disrupting DNA synthesis.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Flucloxacillin: Contraindicated in patients with a history of penicillin allergy.

Breastfeeding: Some antibiotics (e.g., tetracyclines, quinolones) are contraindicated in breastfeeding women due to potential harm to the infant.

b) Second-Line Therapy:

Clarithromycin: For penicillin-allergic patients, 500 mg orally twice daily.

Cephalexin: 500 mg orally four times daily, used in cases where *Staphylococcus aureus* is resistant to first-line treatments.

Alternative Drainage Procedures:

Surgical Drainage: Indicated if repeated needle aspiration is unsuccessful, or the abscess is large and complex.

8. Routine Monitoring and Follow-Up

a) Clinical Monitoring:

Regular review of symptoms and breast examination to assess response to treatment and ensure resolution of infection.

b) Ultrasound Monitoring:

Follow-up ultrasound may be required to confirm complete drainage of the abscess and ensure no recurrence.

c) Breastfeeding Support:

Lactation advice to ensure proper breastfeeding techniques and avoid milk stasis, which can lead to recurrence.

9. Complications of Breast Abscess/Mastitis

a) Chronic Recurrent Mastitis:

Can develop in cases of untreated or inadequately treated mastitis, leading to frequent inflammation and discomfort.

b) Fistula Formation:

A rare complication where an abnormal connection forms between the abscess cavity and the skin.

c) Sepsis:

Untreated breast abscesses can lead to systemic infection, requiring more aggressive intervention and hospitalisation.

d) Breastfeeding Difficulties:

Breast abscess and mastitis may cause pain and difficulties with breastfeeding, leading to early cessation of breastfeeding.

Summary of Key Points for Breast Abscess and Mastitis

Mastitis is an inflammation of the breast tissue, often seen in breastfeeding women, while **breast abscess** represents a more severe infection with pus collection.

Diagnosis is largely clinical, with **ultrasound** confirming the presence of an abscess.

First-line therapy includes **antibiotics** (e.g., flucloxacillin) and **breast milk drainage**, with **needle aspiration** for abscesses.

Routine follow-up ensures the resolution of infection, and complications such as sepsis or recurrent abscesses are addressed.

This structured guide follows UK-based **NICE guidelines** for managing mastitis and breast abscesses in both lactating and non-lactating women.

27. Breast Cancer

1. Detailed Definition of Breast Cancer

Breast cancer is a malignant tumour that originates from the cells of the breast. It is one of the most common cancers in women, although it can also affect men. Breast cancer is categorised into different types based on the part of the breast from which it originates:

Ductal Carcinoma: Begins in the cells lining the milk ducts.

Lobular Carcinoma: Starts in the lobules, the glands that produce milk.

Invasive (spreading to surrounding tissues) or **non-invasive** (confined to the ducts or lobules).

Breast cancer can also be classified by the presence of certain hormone receptors, such as **oestrogen receptor-positive (ER+)**, **progesterone receptor-positive (PR+)**, or **HER2-positive**, which influence treatment options.

2. Common Presenting Complaints and Symptoms

Breast cancer often presents with a variety of signs and symptoms, though early stages may be asymptomatic:

a) **Breast Lump:**

The most common symptom, usually painless, hard, and irregularly shaped.

b) **Breast Changes:**

Thickening or swelling of part of the breast.

Dimpling or puckering of the skin (peau d'orange appearance).

Changes in the size, shape, or appearance of the breast.

c) **Nipple Changes:**

Inversion or retraction of the nipple.

Nipple discharge, which may be bloodstained or clear.

d) **Axillary Lymphadenopathy:**

Swelling or palpable lumps in the axillary (armpit) lymph nodes due to metastatic spread.

e) **Other Symptoms:**

Skin irritation or ulceration.

Pain in the breast or nipple, although breast pain is not a common symptom of cancer.

3. First-Line Investigations

Initial evaluation of a suspected breast cancer includes a combination of imaging, biopsy, and laboratory tests:

a) **Mammography:**

What it measures: X-ray imaging of the breast.

Purpose: First-line imaging for detecting masses, calcifications, or abnormal tissue. It is the standard screening tool for women over 50 and those at high risk.

b) **Breast Ultrasound:**

What it examines: Uses sound waves to create images of the breast tissue.

Purpose: Differentiates between solid masses (likely cancerous) and fluid-filled cysts (usually benign).

c) Core Needle Biopsy:

What it measures: Tissue sample taken from the suspicious area.

Purpose: Confirms the diagnosis by identifying cancer cells and their type, grade, and receptor status (ER, PR, HER2).

d) MRI (Magnetic Resonance Imaging):

What it examines: Provides detailed images of breast tissue using magnetic fields.

Purpose: Used in dense breast tissue or when mammography results are unclear, and for assessing the extent of cancer.

e) Blood Tests (FBC, LFTs, U&Es):

What they measure: Full blood count, liver and kidney function.

Purpose: Baseline bloods before treatment, especially if chemotherapy or surgery is planned.

4. Explanation of Investigations

a) Mammography:

A low-dose X-ray of the breast that can detect tumours or abnormalities that are too small to feel. It's the primary screening tool for early detection of breast cancer.

b) Core Needle Biopsy:

This procedure removes a small sample of tissue from the suspicious area for microscopic examination to confirm the presence of cancer cells and provide details on tumour grade and hormone receptor status.

c) Breast Ultrasound:

Used in conjunction with mammography, particularly in women with dense breast tissue or for evaluating specific abnormalities seen on mammograms.

5. Diagnostic Criteria for Breast Cancer

Breast cancer is diagnosed based on a combination of clinical findings, imaging, and histopathology from a biopsy. Key diagnostic information includes:

Tumour Type: Ductal, lobular, or other types.

Receptor Status:

ER+ and PR+: Indicates sensitivity to hormones like oestrogen and progesterone.

HER2-positive: A more aggressive form, driven by the HER2 protein.

NICE Guidelines recommend the **triple assessment** (clinical examination, imaging, and biopsy) for the diagnosis of suspected breast cancer.

6. First-Line Therapy According to Guidelines

The treatment of breast cancer is guided by the type, stage, and receptor status of the tumour. Management is typically multimodal, combining surgery, systemic therapies, and radiation therapy.

a) Surgical Management:

Breast-Conserving Surgery (Lumpectomy):

Indication: Suitable for early-stage cancers. Involves removing the tumour with a margin of healthy tissue.

Mastectomy:

Indication: Required for larger tumours or multicentric disease. Involves removing the entire breast, with or without immediate reconstruction.

Sentinel Lymph Node Biopsy:

Mechanism: Identifies the first lymph node to which cancer cells are likely to spread to determine if lymph nodes are involved.

b) Systemic Therapies:

Endocrine Therapy (Hormone Therapy):

Tamoxifen: 20 mg orally once daily for ER+ breast cancer.

Mechanism: Blocks oestrogen receptors, preventing the hormone from promoting cancer cell growth.

Aromatase Inhibitors (e.g., Anastrozole): 1 mg orally once daily for post-menopausal women with ER+ breast cancer.

Mechanism: Lowers oestrogen levels by inhibiting the enzyme aromatase, reducing cancer growth.

Chemotherapy:

Indication: Used for triple-negative, HER2-positive, or high-risk ER+ cancers.

Common Regimen: Combination of agents such as **doxorubicin, cyclophosphamide, and paclitaxel**.

HER2-Targeted Therapy:

Trastuzumab (Herceptin): 8 mg/kg IV initially, followed by 6 mg/kg every 3 weeks for HER2-positive breast cancer.

Mechanism: A monoclonal antibody that binds to the HER2 receptor, inhibiting cancer cell growth.

c) **Radiation Therapy:**

Indication: Post-surgery (especially after breast-conserving surgery) to reduce the risk of local recurrence.

Mechanism: Uses high-energy X-rays to kill cancer cells in the breast and surrounding areas.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Tamoxifen: Contraindicated in women with a history of thromboembolic events or endometrial cancer due to the increased risk of these conditions.

Trastuzumab: Avoid in patients with pre-existing heart failure or those who develop cardiotoxicity during treatment.

b) **Second-Line Therapy:**

Fulvestrant: 500 mg intramuscular injection every 28 days.

Mechanism: ER antagonist used when disease progresses on tamoxifen or aromatase inhibitors.

Capecitabine: 1,250 mg/m² orally twice daily for 14 days followed by a 7-day rest period.

Mechanism: A chemotherapy drug that inhibits DNA synthesis, used in metastatic or recurrent breast cancer.

8. Routine Monitoring and Follow-Up

a) **Follow-up Mammography:**

Annual or biennial mammography for surveillance in women treated for breast cancer.

b) **Blood Tests:**

Regular blood tests, including liver and kidney function, particularly during chemotherapy or endocrine therapy, to monitor for side effects.

c) **Bone Density Scans:**

Monitoring bone health in patients on aromatase inhibitors, which can reduce bone density and increase the risk of osteoporosis.

d) **Cardiac Monitoring:**

For patients on trastuzumab, regular echocardiograms are required to monitor for cardiotoxicity.

9. Complications of Breast Cancer

a) **Lymphoedema:**

Swelling of the arm due to lymph node removal or radiation therapy.

b) **Metastasis:**

Breast cancer can metastasise to the bones, lungs, liver, or brain, leading to additional symptoms and complications.

c) **Recurrence:**

There is a risk of local recurrence in the breast or distant metastasis, particularly in higher-stage or aggressive cancers.

d) **Cardiotoxicity:**

Certain chemotherapy agents (e.g., doxorubicin) and HER2-targeted therapies can cause heart damage, leading to heart failure.

Summary of Key Points for Breast Cancer

Breast cancer is the most common cancer in women, with several subtypes, including hormone receptor-positive and HER2-positive forms.

Diagnosis is based on the **triple assessment** of clinical examination, imaging, and biopsy.

Treatment is multimodal, often involving surgery, systemic therapies (endocrine, chemotherapy, targeted therapies), and radiation.

Regular monitoring and follow-up are essential to detect recurrence and manage complications.

28. Breast Cysts

1. Detailed Definition of Breast Cysts

Breast cysts are fluid-filled sacs within the breast tissue, commonly benign, and often part of **fibrocystic breast changes**. They are most prevalent in women aged 35-50 and those approaching menopause, though they can occur at any age. Breast cysts can vary in size and may be **simple cysts** (completely fluid-filled and benign) or **complex cysts** (containing debris or septations, potentially requiring further evaluation). Breast cysts are usually non-cancerous and often resolve or remain stable over time.

2. Common Presenting Complaints and Symptoms

Patients with breast cysts may present with the following symptoms:

a) **Breast Lump:**

A round, smooth, or oval lump that is usually movable and may vary in size with the menstrual cycle. Cysts can range from small to several centimetres in diameter.

b) **Breast Tenderness or Pain:**

Cysts can cause localised discomfort or pain, especially before menstruation when they may enlarge.

c) Fluctuation in Size:

The size of the cyst may change in relation to hormonal fluctuations during the menstrual cycle, growing larger and more tender before menstruation and shrinking afterward.

d) No Symptoms:

Many breast cysts are asymptomatic and are discovered incidentally during imaging or self-examination.

e) Nipple Discharge:

In some cases, there may be clear or straw-coloured discharge from the nipple, especially in larger cysts.

3. First-Line Investigations

Diagnosis of breast cysts is based on imaging studies and clinical examination:

a) Breast Ultrasound:

What it measures: Uses sound waves to differentiate between solid masses and fluid-filled cysts.

Purpose: First-line imaging to confirm the cystic nature of a breast lump and assess whether it is simple or complex.

b) Mammography:

What it examines: X-ray of the breast to detect abnormalities or masses.

Purpose: Commonly used in women over 40 or as part of routine screening. It helps identify any suspicious changes or to confirm the diagnosis in older women where dense breast tissue may obscure cysts.

c) Fine-Needle Aspiration (FNA):

What it measures: Uses a thin needle to aspirate fluid from the cyst.

Purpose: Confirms the diagnosis if the lump is a cyst and provides symptomatic relief if the cyst is painful or large. The fluid can also be sent for cytology if bloodstained or unusual.

d) Breast MRI (rarely used):

What it examines: Provides detailed images of the breast.

Purpose: Used in cases where ultrasound and mammography are inconclusive, or in women at high risk for breast cancer.

4. Explanation of Investigations

a) Breast Ultrasound:

This is the primary investigation for distinguishing between solid lumps and fluid-filled cysts. Simple cysts appear as anechoic (dark) structures with well-defined borders, while complex cysts may show internal echoes or septations.

b) Fine-Needle Aspiration (FNA):

Used to both diagnose and treat symptomatic breast cysts. Aspiration of clear, straw-coloured fluid confirms the benign nature of the cyst. Bloody or unusual fluid may warrant further cytological examination.

5. Diagnostic Criteria for Breast Cysts

Breast cysts are usually diagnosed based on clinical examination and confirmed by ultrasound or FNA. Key features include:

Simple Cysts: Fluid-filled, well-defined, and benign. These do not require further treatment unless symptomatic.

Complex Cysts: These may have thicker walls, septations, or internal debris and might require further investigation (e.g., biopsy) to rule out malignancy.

According to **NICE guidelines**, simple breast cysts typically require no further action unless symptomatic, whereas complex cysts may need more investigation.

6. First-Line Therapy According to Guidelines

Most breast cysts do not require specific treatment unless they are large, painful, or recurrent. Management is based on the patient's symptoms and the characteristics of the cyst.

a) Conservative Management:

Reassurance: For asymptomatic simple cysts, patients are reassured about the benign nature of the cyst, and no further treatment is needed.

Observation: Regular self-examinations and routine clinical follow-up (every 6-12 months) may be recommended for complex cysts or in patients with multiple cysts.

b) Fine-Needle Aspiration (FNA):

Indication: For symptomatic relief in large or painful cysts, or when the diagnosis is uncertain.

Mechanism: Drains the cyst fluid, leading to resolution of the lump and relief of pain. Recurrent cysts may require repeated aspirations.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

FNA: Contraindicated if there is suspicion of malignancy or if the cyst is located near vital structures that may be at risk during the procedure.

b) Second-Line Therapy:

Surgical Excision:

Indication: If a cyst is recurrent, complex, or shows atypical features on imaging or cytology, surgical excision may be performed to rule out malignancy.

Mechanism: Involves removing the cyst and surrounding tissue for histological examination.

Oral Contraceptives:

Indication: In women with recurrent or multiple cysts, hormonal therapy such as low-dose oral contraceptives may help reduce the formation of new cysts.

Mechanism: Regulates hormonal fluctuations that may contribute to cyst formation.

8. Routine Monitoring and Follow-Up

a) **Regular Clinical Examination:**

Women with a history of breast cysts should be encouraged to perform regular self-examinations and report any new changes to their GP.

b) **Ultrasound Follow-Up:**

In cases of complex cysts or recurrent cysts, follow-up ultrasound is often recommended every 6-12 months to monitor for changes.

c) **Symptom Monitoring:**

Patients should report any new pain, rapid growth of the cyst, or other suspicious symptoms (e.g., nipple discharge) to their healthcare provider.

9. Complications of Breast Cysts

a) **Infection:**

Although rare, a breast cyst can become infected, leading to pain, redness, warmth, and potentially abscess formation, requiring antibiotics and drainage.

b) **Recurrent Cysts:**

Some women may develop new or recurrent cysts, especially in the perimenopausal period.

c) **Malignancy:**

Although simple breast cysts are benign, complex cysts with solid components or atypical features may harbour malignancy and require biopsy to exclude cancer.

Summary of Key Points for Breast Cysts

Breast cysts are benign, fluid-filled sacs that are commonly found in premenopausal women, often as part of fibrocystic breast changes.

Diagnosis is confirmed by **ultrasound** or **fine-needle aspiration** to differentiate cysts from solid masses.

Most simple cysts require no treatment, but large or painful cysts can be drained for symptom relief.

Complex cysts may need further evaluation or biopsy to exclude malignancy.

Regular self-examination and clinical follow-up are recommended to monitor for any new changes or recurrence.

29. Fibroadenoma

1. Detailed Definition of Fibroadenoma

Fibroadenoma is a benign (non-cancerous) breast tumour, composed of glandular and fibrous tissue. It is the most common benign breast lump in women, particularly in those aged 15 to 35. Fibroadenomas are usually well-circumscribed, mobile, and painless lumps. They can be classified into:

Simple Fibroadenomas: Uniform and non-complex, with no increased risk of breast cancer.

Complex Fibroadenomas: Contain cysts or calcifications, and although benign, may slightly increase the risk of breast cancer.

Fibroadenomas are thought to arise due to the proliferation of both stromal and epithelial tissue in the breast and are often hormone-sensitive, growing during pregnancy or hormone replacement therapy.

2. Common Presenting Complaints and Symptoms

Patients with fibroadenoma typically present with:

a) **Breast Lump:**

A painless, smooth, firm, and mobile lump.

Often described as “rubbery” or “marble-like” in texture.

Can vary in size from a few millimetres to several centimetres.

b) **No Pain:**

Fibroadenomas are generally non-tender, although some women may experience mild discomfort, especially before menstruation.

c) **Changes in Size:**

The lump may increase in size during pregnancy, with hormonal changes, or when taking oral contraceptives, but often remains stable or shrinks after menopause.

3. First-Line Investigations

Diagnosis of fibroadenoma is confirmed by imaging and biopsy if needed:

a) **Breast Ultrasound:**

What it measures: Uses sound waves to provide an image of the breast tissue.

Purpose: First-line investigation, especially in younger women under 35, to differentiate fibroadenomas from other breast masses. Fibroadenomas appear as well-defined, homogenous, and oval-shaped lesions.

b) Mammography:

What it examines: X-ray imaging of the breast tissue.

Purpose: Often used in women over 40 or those with a higher risk of breast cancer. Fibroadenomas appear as well-defined, round, or lobulated masses with smooth edges on mammography.

c) Core Needle Biopsy:

What it measures: Tissue sample taken from the lump for microscopic examination.

Purpose: Performed if the diagnosis is uncertain after imaging or if the lump is atypical in appearance or rapidly growing. A biopsy confirms the benign nature of the lump and excludes malignancy.

4. Explanation of Investigations

a) Breast Ultrasound:

A non-invasive imaging test that uses sound waves to create images of breast tissue. It helps distinguish between solid lumps (like fibroadenomas) and cystic lesions.

b) Core Needle Biopsy:

Involves removing a small tissue sample from the lump with a needle. This tissue is examined under a microscope to confirm that the fibroadenoma is benign and not cancerous.

5. Diagnostic Criteria for Fibroadenoma

Fibroadenomas are diagnosed based on clinical examination, imaging, and sometimes biopsy. Diagnostic features include:

Ultrasound: A solid, well-circumscribed, homogenous, oval mass with smooth borders.

Mammogram: A well-defined, round or lobulated mass with no microcalcifications or irregular margins.

Core Biopsy: Confirms the fibroadenoma diagnosis by revealing a benign proliferation of both stromal and glandular tissue.

NICE guidelines recommend using imaging (ultrasound and mammography) to confirm a benign diagnosis in younger women and a biopsy when there is diagnostic uncertainty or atypical features.

6. First-Line Therapy According to Guidelines

Most fibroadenomas do not require treatment unless they cause symptoms or are rapidly enlarging. Management is often conservative:

a) Conservative Management:

Reassurance: Most fibroadenomas are benign and do not require removal unless they are symptomatic or there is concern about malignancy. Reassurance is usually sufficient, particularly for smaller fibroadenomas (<3 cm).

Observation: Regular clinical and imaging follow-up may be advised, especially in younger women, to monitor for changes in size or characteristics.

b) Surgical Excision:

Indication: Recommended if the fibroadenoma is larger than 3 cm, growing, or causing discomfort. Excision may also be chosen if the patient is anxious about the lump.

Procedure: A lumpectomy (removal of the lump) is performed under local or general anaesthesia, depending on the size and location of the fibroadenoma.

c) Cryoablation:

Indication: A minimally invasive procedure used for small, symptomatic fibroadenomas.

Mechanism: A probe is inserted into the lump, and extreme cold is applied to freeze and destroy the fibroadenoma, which is gradually absorbed by the body.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgical excision: Not routinely recommended for small, asymptomatic fibroadenomas as they pose no risk and surgery may result in unnecessary scarring.

b) Second-Line Therapy:

Repeat Biopsy: If the fibroadenoma shows atypical features or rapid growth, a repeat biopsy may be required to exclude malignancy.

Vacuum-Assisted Biopsy/Excision: For larger or symptomatic fibroadenomas, this minimally invasive procedure uses suction to remove the lump without the need for open surgery.

8. Routine Monitoring and Follow-Up

a) Regular Breast Examination:

Patients are advised to perform self-breast examinations regularly and report any new changes or growth of the lump to their GP.

b) Imaging Follow-Up:

Annual or biennial ultrasound or mammography may be recommended to monitor for changes in the size or appearance of the fibroadenoma.

9. Complications of Fibroadenoma

a) **Enlargement:**

Although benign, fibroadenomas can enlarge, particularly in response to hormonal changes, potentially causing discomfort or anxiety.

b) **Complex Fibroadenoma:**

In rare cases, fibroadenomas may contain calcifications or cystic components, which slightly increase the risk of breast cancer. Complex fibroadenomas may require more frequent monitoring or surgical excision.

c) **Patient Anxiety:**

Despite the benign nature of fibroadenomas, some patients may experience anxiety and prefer removal for peace of mind.

Summary of Key Points for Fibroadenoma

Fibroadenomas are common benign breast lumps, typically seen in younger women, and often present as painless, mobile, and firm masses.

Diagnosis is primarily confirmed through **ultrasound** and, if needed, **core needle biopsy**.

Treatment is usually conservative, with surgical excision reserved for large, symptomatic, or growing fibroadenomas.

Regular follow-up with clinical examinations and imaging is recommended to monitor for changes or complications.

30. Benign Breast Disease

1. Detailed Definition of Benign Breast Disease

Benign breast disease encompasses a wide range of non-cancerous conditions affecting the breast tissue. These conditions are common and can present with symptoms similar to those of breast cancer, such as lumps, pain, and nipple discharge, but they do not pose the same risk of malignancy. Benign breast diseases include fibrocystic changes, fibroadenomas, breast cysts, duct ectasia, and fat necrosis. They can be classified into:

Non-proliferative: Conditions with no increased risk of breast cancer, such as simple cysts and fibrocystic changes.

Proliferative without atypia: Conditions with a slightly increased risk of cancer, such as sclerosing adenosis and papillomas.

Atypical hyperplasia: A pre-malignant condition with a higher risk of developing breast cancer.

2. Common Presenting Complaints and Symptoms

Patients with benign breast disease may present with the following symptoms:

a) **Breast Lumps:**

Most common in fibroadenomas, cysts, or fat necrosis. Lumps are usually smooth, mobile, and well-circumscribed.

b) Breast Pain (Mastalgia):

Cyclical breast pain linked to the menstrual cycle is common in fibrocystic changes and can affect one or both breasts.

c) Nipple Discharge:

Can be clear, milky, or greenish in conditions like duct ectasia. Bloody discharge may suggest a benign papilloma but needs further evaluation.

d) Breast Swelling and Tenderness:

Common in fibrocystic changes, particularly before menstruation, when the breasts may feel lumpy or tender.

e) Skin or Nipple Changes:

Retraction or dimpling of the skin may occur in fat necrosis or other inflammatory conditions but can mimic malignancy.

3. First-Line Investigations

Investigations are aimed at ruling out malignancy and confirming a benign diagnosis. Common first-line investigations include:

a) Breast Ultrasound:

What it measures: Uses sound waves to differentiate between solid and fluid-filled lesions.

Purpose: First-line imaging for younger women and to evaluate cystic lesions. It helps confirm benign conditions such as cysts, fibroadenomas, and fat necrosis.

b) Mammography:

What it examines: X-ray of the breast, used to identify masses, calcifications, and other abnormalities.

Purpose: Preferred imaging in women over 40 or as part of routine breast cancer screening. Used to assess for suspicious changes and confirm benign conditions.

c) Fine-Needle Aspiration (FNA):

What it measures: Samples fluid from cysts or tissue from solid masses.

Purpose: Used to diagnose cysts (by aspirating fluid) and fibroadenomas or rule out malignancy when a solid lump is present.

d) Core Needle Biopsy:

What it measures: Removes a small sample of tissue for histopathological examination.

Purpose: Confirms diagnosis when imaging is inconclusive or when there are atypical features. It helps rule out breast cancer.

4. Explanation of Investigations

a) **Breast Ultrasound:**

This is particularly useful for distinguishing between cysts and solid masses. Simple cysts are anechoic (dark) with well-defined borders, while solid benign lesions like fibroadenomas are hypoechoic with smooth margins.

b) **Core Needle Biopsy:**

This test is essential when there is diagnostic uncertainty or atypical imaging findings. It provides a definitive tissue diagnosis, confirming benign conditions such as fibroadenomas or identifying atypical hyperplasia, which may require further management.

5. Diagnostic Criteria for Benign Breast Disease

Diagnosis of benign breast disease is made based on clinical findings, imaging, and, if necessary, biopsy results. Key conditions include:

Fibrocystic Changes: Lumpy, tender breasts, particularly before menstruation, often confirmed by ultrasound showing cysts and fibrous tissue.

Fibroadenoma: A solid, mobile, and well-circumscribed lump, typically seen on ultrasound or confirmed by biopsy.

Breast Cysts: Fluid-filled sacs, easily identified on ultrasound and diagnosed via FNA.

Duct Ectasia: Dilated ducts near the nipple, often presenting with nipple discharge, confirmed by mammography or ultrasound.

Fat Necrosis: Palpable lumps that can mimic malignancy but are benign. Confirmed by ultrasound or biopsy if there are suspicious features.

NICE guidelines recommend using a combination of clinical examination, imaging, and biopsy when necessary to confirm a diagnosis of benign breast disease and to rule out malignancy.

6. First-Line Therapy According to Guidelines

Management of benign breast disease depends on the condition and severity of symptoms. Most conditions are managed conservatively, but some may require intervention.

a) **Conservative Management:**

Reassurance: Most benign breast conditions do not increase the risk of cancer, and patients can be reassured of the benign nature of their symptoms.

Analgesia: For mastalgia, simple analgesics such as ibuprofen or paracetamol can be used for pain relief.

Lifestyle Modifications: Reducing caffeine intake, wearing a well-fitted bra, and dietary changes (e.g., reducing fat intake) can help with cyclical breast pain in fibrocystic changes.

b) **Aspiration for Symptomatic Cysts:**

Indication: For large or painful cysts, FNA can relieve symptoms by draining the fluid.

Mechanism: Provides immediate symptom relief, and fluid can be sent for cytology if the appearance is unusual.

c) **Surgical Excision:**

Indication: Reserved for large, symptomatic fibroadenomas or in cases of diagnostic uncertainty (e.g., complex cysts or papillomas).

Mechanism: The lump is surgically removed, particularly if it causes anxiety, discomfort, or continues to grow.

d) **Hormonal Therapy:**

Indication: For women with severe cyclical breast pain unresponsive to lifestyle changes, hormonal treatments such as oral contraceptives or **danazol** (a synthetic steroid) may be used.

Mechanism: Modulates the hormonal changes that contribute to fibrocystic breast changes, reducing pain and swelling.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Hormonal Therapy: Not recommended for women with contraindications to hormonal medications (e.g., history of thromboembolic events, liver disease).

b) **Second-Line Therapy:**

Danazol: Used for refractory mastalgia, but side effects (e.g., weight gain, acne, hirsutism) often limit its use.

Surgical Excision: In recurrent or persistent benign lesions, surgery may be performed to prevent recurrence or to obtain a definitive diagnosis.

8. Routine Monitoring and Follow-Up

a) **Regular Breast Examination:**

Patients should be encouraged to perform self-breast examinations regularly and report any new or persistent lumps, changes in size, or nipple discharge.

b) **Imaging Follow-Up:**

For conditions like fibroadenomas or complex cysts, regular follow-up with ultrasound or mammography (every 6-12 months) may be recommended to monitor for changes.

c) **Biopsy Monitoring:**

If biopsy reveals atypical hyperplasia, patients may require more frequent surveillance due to an increased risk of breast cancer.

9. Complications of Benign Breast Disease

a) **Recurrence:**

Conditions like breast cysts and fibroadenomas can recur, requiring repeated aspiration or surgical excision in some cases.

b) **Infection:**

Rarely, breast cysts or duct ectasia can become infected, leading to abscess formation, which may require drainage and antibiotics.

c) **Atypical Hyperplasia:**

Though benign, this condition carries a higher risk of progressing to breast cancer, necessitating closer monitoring and sometimes prophylactic treatments.

d) **Patient Anxiety:**

Despite reassurance, some women may experience anxiety about benign lumps, leading to requests for further imaging or surgical removal for peace of mind.

Summary of Key Points for Benign Breast Disease

Benign breast diseases include a variety of non-cancerous conditions, such as fibrocystic changes, fibroadenomas, cysts, and duct ectasia.

Diagnosis is based on clinical examination, imaging (ultrasound or mammography), and sometimes biopsy to confirm the benign nature of the condition.

Most benign breast diseases do not require treatment beyond reassurance, though aspiration, hormonal therapy, or surgery may be indicated for symptomatic cases.

Routine follow-up and self-examination are important to monitor for changes and ensure any concerning features are investigated promptly.

Care of the Elderly

31. Assessment of Needs and Discharge Planning

1. Detailed Definition of Assessment of Needs and Discharge Planning

Assessment of Needs is a comprehensive evaluation conducted for elderly patients to identify their medical, psychological, and social requirements to ensure safe, effective care both in the hospital and after discharge. This process involves multidisciplinary input to address physical health, cognitive function, mobility, activities of daily living (ADLs), social support, and the patient's living environment.

Discharge Planning is the process of preparing an elderly patient for a safe transition from hospital to home or another care setting. It begins early during the hospital stay and involves ensuring that the patient's needs are met, including medical management, rehabilitation, and social care. Proper discharge planning reduces the risk of readmission and ensures continuity of care post-discharge.

2. Key Components of Assessment of Needs

The assessment of an elderly patient's needs is multidisciplinary and includes the following key areas:

a) **Medical Assessment:**

Comprehensive medical evaluation, including a review of acute and chronic conditions.

Consideration of comorbidities such as diabetes, hypertension, and heart failure, and their impact on the patient's function and prognosis.

b) **Functional Assessment:**

Activities of Daily Living (ADLs): Evaluates basic self-care tasks such as dressing, bathing, toileting, feeding, and mobility.

Instrumental Activities of Daily Living (IADLs): Includes more complex activities such as managing finances, medication, and transportation.

c) **Cognitive Assessment:**

Screening for cognitive impairment using tools such as the **Mini-Mental State Examination (MMSE)** or **Montreal Cognitive Assessment (MoCA)**.

Identification of conditions such as dementia, delirium, or depression that may affect discharge planning and care needs.

d) **Psychological and Emotional Well-being:**

Assessment of mental health, including anxiety, depression, and mood disorders, which are common in elderly patients.

e) **Nutritional Assessment:**

Evaluating nutritional status, including risk of malnutrition or dehydration, using screening tools like the **Malnutrition Universal Screening Tool (MUST)**.

f) **Social and Environmental Assessment:**

Assessment of the patient's home environment, social support network, and financial resources.

Identification of caregivers and potential support systems or community resources that can be accessed.

g) **Mobility and Fall Risk:**

Assessment of mobility, balance, and risk of falls using tools such as the **Timed Up and Go (TUG) Test**.

Consideration of assistive devices (e.g., walking aids) or need for physiotherapy.

h) **Medication Review:**

A detailed review of current medications to assess appropriateness, polypharmacy, and potential drug interactions or side effects.

3. Key Components of Discharge Planning

Discharge planning is essential for a smooth transition from the hospital to the next care setting. It includes:

a) Early Planning:

Begins soon after admission, involving the patient, family, carers, and the multidisciplinary team (MDT), including doctors, nurses, social workers, and allied health professionals (e.g., physiotherapists, occupational therapists).

b) Medical Management Post-Discharge:

Establish a clear management plan for ongoing medical issues, including follow-up appointments and referrals to specialists.

Ensure adequate supply and instructions for any medications to be taken after discharge.

c) Rehabilitation and Support Services:

Referral to appropriate rehabilitation services (e.g., physiotherapy, occupational therapy) for patients needing further functional improvement post-discharge.

Consideration of home adaptations or equipment (e.g., stairlifts, grab rails) to support safe mobility at home.

d) Social Care and Support:

Involvement of social services to assess for care packages, including personal care, home help, and community services.

Arrangements for carers or domiciliary care if the patient requires assistance with ADLs.

e) Safe Home Environment:

Assessment of the home environment to ensure it is safe for the patient to return, including considerations such as heating, accessibility, and cleanliness.

f) Continuity of Care:

Coordination with primary care services (e.g., GP, district nurses) for ongoing monitoring, particularly for those with complex medical needs.

g) Communication:

Clear communication with the patient and family members, ensuring they understand the discharge plan, follow-up requirements, and any signs of potential complications.

4. Multidisciplinary Team (MDT) Involvement in Needs Assessment and Discharge Planning

Effective assessment and discharge planning for elderly patients rely on input from the MDT:

Doctors: Provide medical assessment and management, ensure that medical needs are addressed, and identify whether the patient is medically fit for discharge.

Nurses: Monitor the patient's clinical progress, educate the patient and family on care needs, and help coordinate discharge planning.

Physiotherapists: Assess mobility and functional ability, provide rehabilitation plans, and recommend mobility aids.

Occupational Therapists: Evaluate the patient's ability to perform ADLs and assess the home environment, recommending adaptations as necessary.

Social Workers: Identify social support needs, arrange care packages, and link patients to community services.

Pharmacists: Conduct medication reviews to optimise treatment and reduce the risk of polypharmacy or adverse effects.

5. Discharge Pathways

The appropriate discharge pathway for elderly patients depends on their needs and abilities:

a) **Home Discharge with Minimal Support:**

For patients who are independent in ADLs and IADLs, minimal support may be required, with follow-up in primary care or specialist clinics.

b) **Home Discharge with Care Package:**

For patients requiring assistance with ADLs, a tailored care package can be arranged, including visits from carers or district nurses.

c) **Discharge to a Rehabilitation Facility:**

For patients requiring further rehabilitation before returning home, discharge to an inpatient rehabilitation unit or intermediate care may be needed.

d) **Discharge to Long-Term Care:**

For patients who are unable to return home due to high levels of dependency, long-term residential or nursing care may be required.

6. Assessment Tools Commonly Used in Needs Assessment

a) **Barthel Index:**

Measures performance in ADLs, such as feeding, bathing, grooming, dressing, and mobility. Used to assess functional status.

b) **MMSE or MoCA:**

Cognitive screening tools used to assess memory, attention, language, and executive function.

c) **Waterlow Score:**

Assesses risk of pressure ulcers in bed-bound or immobile patients.

d) **MUST (Malnutrition Universal Screening Tool):**

Identifies patients at risk of malnutrition by assessing weight, BMI, and nutritional intake.

7. Challenges in Needs Assessment and Discharge Planning

a) **Complex Medical and Social Needs:**

Elderly patients often have multiple comorbidities, cognitive impairments, and social care needs, making assessment and discharge planning more complex.

b) **Inadequate Resources:**

Delays in discharge can occur due to limited availability of rehabilitation services, care home placements, or social care packages.

c) **Communication Issues:**

Ensuring clear communication between the MDT, patient, and family is crucial but can be challenging, especially if there are language barriers or cognitive impairments.

d) **Risk of Hospital Readmission:**

Inadequate discharge planning can lead to early hospital readmission, particularly in patients with chronic conditions or insufficient post-discharge support.

Summary of Key Points for Assessment of Needs and Discharge Planning

The assessment of needs is a comprehensive, multidisciplinary process that evaluates the medical, functional, cognitive, and social requirements of elderly patients.

Discharge planning involves early, structured preparation for the patient's safe transition from hospital to home or another care setting.

Involvement of the MDT, early identification of support services, and clear communication with the patient and family are essential for successful discharge.

Challenges include managing complex medical and social needs, ensuring resource availability, and preventing readmission through proper post-discharge care.

32. Blackouts and Faints

1. Detailed Definition of Blackouts and Faints

Blackouts (syncope) and **faints** refer to temporary loss of consciousness or postural tone, often due to a transient reduction in cerebral blood flow. These episodes are common in elderly patients and can have various causes, ranging from benign (e.g., vasovagal syncope) to serious (e.g., cardiac arrhythmias, orthostatic hypotension). The evaluation of blackouts and faints in elderly patients is crucial because they are at higher risk for injury and recurrent episodes due to comorbidities and age-related physiological changes.

2. Common Presenting Complaints and Symptoms

Patients experiencing blackouts and faints may present with:

a) **Sudden Loss of Consciousness:**

Transient and often resolves spontaneously within seconds to minutes. It is usually followed by rapid recovery without postictal confusion (as seen in seizures).

b) **Lightheadedness or Dizziness:**

Preceding symptoms such as feeling faint or dizzy, often described as a "near fainting" sensation (presyncope).

c) **Pallor and Sweating:**

Some patients may exhibit sweating and pallor prior to or during a fainting episode.

d) **Postural Instability:**

Some patients experience fainting when standing or changing position (orthostatic hypotension).

e) **Palpitations or Chest Pain:**

May occur in cardiac-related syncope or arrhythmias.

f) **Injury Due to Fall:**

Syncope can result in falls, leading to head trauma, fractures, or other injuries.

3. Common Causes of Blackouts and Faints in the Elderly

The causes of blackouts and faints are often multifactorial in elderly patients and include:

a) **Vasovagal Syncope:**

A common benign cause, often triggered by emotional stress, pain, or prolonged standing. It is usually preceded by symptoms such as nausea, lightheadedness, and sweating.

b) **Orthostatic Hypotension:**

A drop in blood pressure upon standing, leading to syncope or near-syncope. It is common in older adults due to age-related changes in blood pressure regulation and can be exacerbated by dehydration, medications (e.g., diuretics, antihypertensives), or autonomic dysfunction.

c) **Cardiac Arrhythmias:**

Bradyarrhythmias (e.g., sick sinus syndrome, heart block) or tachyarrhythmias (e.g., atrial fibrillation, ventricular tachycardia) can cause sudden loss of consciousness due to insufficient cardiac output.

d) **Aortic Stenosis:**

Aortic stenosis can lead to syncope, especially with exertion, due to the inability of the heart to increase output through a narrowed valve.

e) Postprandial Hypotension:

A drop in blood pressure after eating, which is more common in the elderly due to altered autonomic responses.

f) Medications:

Common medications in the elderly (e.g., beta-blockers, diuretics, nitrates) can contribute to hypotension, bradycardia, or arrhythmias.

g) Seizures:

Seizures may present as blackouts, but these are typically accompanied by postictal confusion, tongue biting, or incontinence.

h) Transient Ischemic Attacks (TIA):

Sudden focal neurological symptoms that may cause temporary loss of consciousness, especially if affecting the brainstem or posterior circulation.

4. First-Line Investigations

Evaluation of blackouts and faints in elderly patients involves a thorough history, physical examination, and targeted investigations to determine the underlying cause:

a) Electrocardiogram (ECG):

What it measures: Assesses heart rhythm and electrical activity.

Purpose: Detects arrhythmias, ischemia, or heart block that may cause syncope. In cases of arrhythmic syncope, it may show bradycardia, atrial fibrillation, or conduction abnormalities.

b) Orthostatic Blood Pressure Measurement:

What it measures: Blood pressure measured when lying, sitting, and standing.

Purpose: Detects orthostatic hypotension, defined as a drop in systolic BP >20 mmHg or diastolic BP >10 mmHg upon standing.

c) Echocardiogram:

What it examines: Provides images of the heart's structure and function.

Purpose: Evaluates for structural heart disease, such as aortic stenosis or cardiomyopathy, that may contribute to syncope.

d) 24-Hour Holter Monitoring:

What it measures: Continuous ECG monitoring over 24 hours.

Purpose: Detects intermittent arrhythmias that may not be captured on a standard ECG.

e) Tilt Table Test:

What it measures: Evaluates the patient's response to changes in position.

Purpose: Used to diagnose vasovagal syncope or orthostatic hypotension if these are suspected but not confirmed by orthostatic BP measurement.

f) Electrolyte Panel (U&Es):

What it measures: Levels of sodium, potassium, calcium, and other electrolytes.

Purpose: Electrolyte imbalances, such as hypokalemia or hypercalcemia, may contribute to syncope or arrhythmias.

g) CT Brain Scan (if indicated):

What it examines: Provides imaging of the brain.

Purpose: Used if there is a suspicion of TIA, stroke, or trauma from falls secondary to blackouts.

5. Explanation of Investigations

a) ECG:

Evaluates cardiac electrical activity to detect arrhythmias or conduction abnormalities that may cause syncope, such as atrial fibrillation or complete heart block.

b) Orthostatic Blood Pressure Measurement:

Tests for orthostatic hypotension by measuring the change in blood pressure as the patient moves from lying to standing. A significant drop indicates an inability of the autonomic system to maintain BP on standing.

c) Echocardiogram:

Assesses heart valves, chambers, and wall motion to identify structural problems like aortic stenosis, which can lead to exertional syncope in elderly patients.

6. Diagnostic Criteria for Blackouts and Faints

The diagnosis of the underlying cause of blackouts and faints is based on clinical assessment, targeted investigations, and elimination of other possible causes. Criteria for diagnosis include:

Vasovagal Syncope: Preceding symptoms of lightheadedness, nausea, or warmth, often triggered by pain, stress, or standing for prolonged periods. No significant abnormalities on ECG or other investigations.

Orthostatic Hypotension: A drop in systolic BP >20 mmHg or diastolic BP >10 mmHg upon standing.

Cardiac Syncope: Diagnosed based on abnormal ECG findings, such as arrhythmias or evidence of ischemic heart disease.

7. First-Line Therapy According to Guidelines

The management of blackouts and faints in elderly patients is guided by the underlying cause:

a) **Vasovagal Syncope:**

Lifestyle Modifications: Encourage patients to avoid triggers (e.g., prolonged standing, dehydration).

Education: Teach patients how to recognise early warning signs and sit or lie down when symptoms begin.

b) **Orthostatic Hypotension:**

Increased Fluid and Salt Intake: Encourage adequate hydration and increased salt intake (if not contraindicated by other conditions).

Medication Review: Adjust or discontinue medications that may cause hypotension (e.g., diuretics, antihypertensives).

Compression Stockings: May help improve venous return and reduce symptoms of postural hypotension.

c) **Cardiac Arrhythmias:**

Pacemaker: Indicated for bradyarrhythmias such as complete heart block.

Antiarrhythmic Therapy: For tachyarrhythmias, medications such as beta-blockers or antiarrhythmics may be prescribed.

Implantable Cardioverter-Defibrillator (ICD): Indicated for patients at risk of ventricular tachycardia or fibrillation.

d) **Aortic Stenosis:**

Aortic Valve Replacement: Recommended for symptomatic severe aortic stenosis to prevent syncope, heart failure, or sudden cardiac death.

e) **Medications:**

Fludrocortisone: May be prescribed for orthostatic hypotension to increase blood volume.

8. Routine Monitoring and Follow-Up

a) **Cardiac Monitoring:**

Patients with cardiac-related syncope should have regular ECGs or Holter monitoring, especially if they are on antiarrhythmic therapy or have a pacemaker.

b) **Medication Review:**

Regular review of medications, particularly those that can cause hypotension, arrhythmias, or electrolyte imbalances, is essential.

c) **Follow-Up with Geriatrician or Cardiologist:**

For patients with recurrent syncope, referral to a specialist may be required for further assessment and management.

9. Complications of Blackouts and Faints

a) Injuries from Falls:

Elderly patients are at high risk of falls during syncope, leading to fractures, head injuries, or soft tissue damage.

b) Recurrent Syncope:

If the underlying cause is not treated, patients may experience repeated episodes, increasing the risk of injury and limiting quality of life.

c) Cardiac Arrest:

In cases of cardiac-related syncope, such as arrhythmias or aortic stenosis, untreated conditions can lead to sudden cardiac death.

Summary of Key Points for Blackouts and Faints in the Elderly

Blackouts and faints (syncope) are common in elderly patients and can be due to various causes, including vasovagal syncope, orthostatic hypotension, cardiac arrhythmias, and structural heart disease.

A thorough history, physical examination, and targeted investigations (e.g., ECG, orthostatic BP, echocardiogram) are essential for diagnosing the underlying cause.

Management is tailored to the specific cause and may include lifestyle modifications, medication adjustments, or interventions like pacemaker insertion.

Regular monitoring and follow-up are important to prevent recurrence and manage complications, especially in patients with high-risk cardiac conditions.

33. Breakdown in Social Circumstances

1. Detailed Definition of Breakdown in Social Circumstances

A **breakdown in social circumstances** refers to a situation where an elderly person's existing social support system becomes insufficient or collapses, making it difficult or unsafe for them to continue living independently. This can be due to a variety of factors, such as the loss of a caregiver, deterioration in physical or cognitive health, financial difficulties, social isolation, or housing issues. In elderly patients, a breakdown in social circumstances can significantly affect their health and wellbeing, leading to hospital admission, delayed discharge, or the need for long-term care planning.

2. Common Presenting Complaints and Symptoms

Elderly patients experiencing a breakdown in social circumstances may present with:

a) Inability to Manage Activities of Daily Living (ADLs):

Difficulty with tasks such as bathing, dressing, eating, toileting, or moving around the home, often due to physical frailty, cognitive decline, or lack of assistance.

b) Deterioration in Physical Health:

Increased risk of malnutrition, dehydration, and falls due to inadequate support at home. Poorly managed chronic conditions such as diabetes or hypertension may worsen.

c) Cognitive Decline:

Cognitive impairments, such as dementia or delirium, may worsen due to social isolation, medication mismanagement, or failure to attend medical appointments.

d) Social Isolation:

Loneliness, depression, and anxiety resulting from the loss of social contacts, such as family or friends. This may be exacerbated by mobility issues or the inability to access community support.

e) Carer Breakdown:

The primary carer (often a spouse or family member) may become ill, overwhelmed, or unable to continue providing care, leading to a crisis situation for the elderly individual.

f) Housing Issues:

Unsafe living conditions, such as inadequate heating, difficulty with stairs, or cluttered environments that increase the risk of falls, may lead to the inability to remain at home.

g) Financial Strain:

Elderly individuals may face difficulties affording essential needs such as food, heating, medications, or home care services, which can contribute to a rapid deterioration in their circumstances.

3. First-Line Investigations and Assessments

When an elderly person experiences a breakdown in social circumstances, a thorough assessment is necessary to determine the underlying causes and appropriate interventions:

a) Comprehensive Geriatric Assessment (CGA):

What it assesses: A multidimensional, multidisciplinary diagnostic process that evaluates medical, psychological, functional, and social factors.

Purpose: Identifies medical, social, and functional needs, helping to formulate a comprehensive care plan.

b) Social Care Assessment:

What it assesses: Conducted by social workers, this evaluation focuses on social support, housing, financial resources, and carer support.

Purpose: Identifies gaps in care provision and potential services that can be accessed to support the patient at home.

c) Activities of Daily Living (ADLs) Assessment:

What it measures: Assesses the patient's ability to perform basic self-care tasks (e.g., dressing, bathing, toileting, feeding).

Purpose: Helps determine the level of care required for the patient to remain independent or the need for additional home care services.

d) Cognitive Assessment:

What it measures: Tools such as the Mini-Mental State Examination (MMSE) or Montreal Cognitive Assessment (MoCA) can be used to assess cognitive function.

Purpose: Identifies cognitive impairment (e.g., dementia, delirium) that may be contributing to the social breakdown.

e) Carer's Assessment:

What it assesses: Evaluates the health and wellbeing of the primary caregiver, their ability to continue providing care, and the support they may need.

Purpose: Identifies if carer fatigue or health problems are contributing to the breakdown in care.

4. Explanation of Assessments

a) Comprehensive Geriatric Assessment (CGA):

A multidisciplinary evaluation that addresses medical, psychological, functional, and social needs, providing a holistic overview of the patient's situation. This process typically involves input from doctors, nurses, physiotherapists, occupational therapists, and social workers.

b) Social Care Assessment:

A formal evaluation by social services to assess the patient's social support, housing situation, and access to community services. The outcome often leads to the provision of home care services, day centres, respite care, or long-term care placement.

c) Carer's Assessment:

Assesses the caregiver's physical and emotional health, recognising the role they play in supporting the patient. If the carer is struggling, interventions such as respite care or additional support services may be arranged.

5. Diagnostic Criteria for Breakdown in Social Circumstances

A breakdown in social circumstances is identified when an elderly patient is no longer able to manage independently or safely in their current environment due to changes in their social support system, housing, or health. Criteria include:

Inability to perform ADLs or IADLs: Demonstrated loss of function in daily tasks such as cooking, cleaning, or managing medications.

Social isolation: Lack of regular social interaction or support from family, friends, or community services.

Carer breakdown: The primary carer is no longer able to provide care due to physical or emotional strain.

Unsafe living environment: The home is no longer safe or accessible due to mobility issues, lack of heating, or increased fall risk.

NICE guidelines emphasise early identification and intervention in cases of social breakdown, focusing on integrated care and multidisciplinary support.

6. First-Line Interventions According to Guidelines

Once a breakdown in social circumstances is identified, the following interventions are typically implemented:

a) Referral to Social Services:

Action: A formal referral is made to social services to assess the patient's needs and implement support.

Outcome: Can lead to the provision of home care packages, personal care support, meals-on-wheels, and access to day centres.

b) Implementation of Care Package:

Action: Care packages tailored to the patient's needs, which may include personal care, domestic help, and medication management.

Outcome: Enables the patient to continue living at home with the appropriate level of support.

c) Occupational Therapy (OT) and Home Adaptations:

Action: OT assessment to provide mobility aids and recommend home adaptations, such as grab rails, stairlifts, or ramps.

Outcome: Increases safety and accessibility, reducing the risk of falls and improving independence.

d) Provision of Respite Care:

Action: Temporary care provided in a care home or by visiting carers to give the primary caregiver a break.

Outcome: Helps prevent carer burnout and allows for the caregiver to recuperate.

e) Community Services and Day Centres:

Action: Referral to community-based services that offer social interaction, physical activities, and respite for carers.

Outcome: Reduces social isolation, promotes mental wellbeing, and offers structured support.

f) Telecare and Alarm Systems:

Action: Installation of alarm systems, fall detectors, or emergency response systems in the home.

Outcome: Provides additional safety and peace of mind for both the patient and caregivers, allowing for rapid response in emergencies.

7. Common Contraindications and Second-Line Interventions

a) **Contraindications:**

Living Independently Without Support: In cases where the patient has severe cognitive impairment or significant physical frailty, returning home without adequate support can pose a significant risk to their safety and wellbeing.

b) **Second-Line Interventions:**

Residential or Nursing Home Placement:

Indication: For patients who cannot safely remain at home, even with a care package, or when carers can no longer provide adequate support.

Mechanism: Offers 24-hour care, medication management, and social interaction in a structured, supportive environment.

Resettlement Services:

Indication: When patients require new housing, resettlement services help identify suitable sheltered accommodation or supported living arrangements.

Mechanism: Provides ongoing care within a more secure and accessible environment, tailored to the patient's needs.

8. Routine Monitoring and Follow-Up

a) **Regular Care Plan Reviews:**

Frequent reviews (every 3-6 months) of the care plan by social services and the healthcare team to assess whether the current level of care is meeting the patient's needs or if further interventions are required.

b) **Ongoing Carer Support:**

Regular check-ins and support for caregivers to ensure they are coping and to offer additional resources if necessary.

c) **Health Monitoring:**

Regular GP visits to monitor the patient's medical conditions and prevent any deterioration that could further complicate social circumstances.

9. Complications of Breakdown in Social Circumstances

a) **Increased Hospital Admissions:**

Frequent hospitalisations due to falls, malnutrition, or poorly managed chronic conditions, often exacerbated by a lack of social support.

b) **Carer Fatigue and Burnout:**

In cases of carer breakdown, the caregiver may become physically or emotionally exhausted, resulting in their inability to continue providing care.

c) **Deterioration in Mental and Physical Health:**

Social isolation, loneliness, and the inability to manage ADLs can lead to depression, anxiety, and physical health deterioration.

d) Institutionalisation:

Failure to adequately address social needs can result in the need for long-term institutional care, which may have been avoidable with earlier intervention.

Summary of Key Points for Breakdown in Social Circumstances

A breakdown in social circumstances in elderly patients can significantly impact their ability to live independently and safely, requiring urgent assessment and intervention.

A **Comprehensive Geriatric Assessment** (CGA) and social care evaluation are essential in identifying the patient's needs and implementing a care plan.

First-line interventions often involve referrals to social services, home adaptations, respite care, and support services to prevent deterioration.

Multidisciplinary follow-up is required to ensure ongoing support and prevent hospital admissions or long-term institutional care.

34. Chronic Cognitive Impairment

1. Detailed Definition of Chronic Cognitive Impairment

Chronic cognitive impairment refers to a long-term decline in cognitive function that affects memory, thinking, learning, decision-making, and daily functioning. It can result from various conditions, including **dementia** (e.g., Alzheimer's disease, vascular dementia), **mild cognitive impairment (MCI)**, and **Parkinson's disease dementia**. Cognitive impairment can range from mild (where daily functioning remains relatively unaffected) to severe (where the individual requires assistance with most activities of daily living). The impairment is progressive in nature and typically worsens over time, impacting the individual's independence, safety, and quality of life.

2. Common Presenting Complaints and Symptoms

Patients with chronic cognitive impairment often present with:

a) Memory Loss:

Difficulty remembering recent events or conversations. Long-term memory may initially be preserved, but short-term memory declines.

b) Language Problems:

Difficulty finding the right words or following conversations. This can result in hesitation or frequent repetition.

c) Disorientation:

Confusion regarding time, place, or familiar environments. Patients may get lost in familiar places or struggle to recognise once-familiar people.

d) Poor Judgment and Decision-Making:

Difficulty making decisions or solving problems, such as handling finances, making appointments, or preparing meals.

e) Personality and Behaviour Changes:

Mood swings, irritability, anxiety, or depression. Some patients may exhibit aggressive or socially inappropriate behaviour.

f) Difficulty with Activities of Daily Living (ADLs):

Challenges with tasks like dressing, bathing, cooking, or managing medications, particularly as the impairment progresses.

g) Worsening of Chronic Conditions:

Patients with cognitive impairment may forget to take medications or attend medical appointments, leading to poor management of other chronic conditions such as diabetes or hypertension.

3. First-Line Investigations

Diagnosis of chronic cognitive impairment involves a combination of clinical assessment, cognitive testing, and imaging to rule out reversible causes and confirm the diagnosis:

a) Cognitive Screening Tools:

Mini-Mental State Examination (MMSE): Assesses orientation, recall, attention, calculation, language, and motor skills.

Montreal Cognitive Assessment (MoCA): A more sensitive test for detecting mild cognitive impairment, focusing on memory, attention, executive function, and visuospatial skills.

Abbreviated Mental Test (AMT): A quick 10-item assessment for cognitive function in older adults.

b) Blood Tests:

What they measure: Full blood count (FBC), urea and electrolytes (U&Es), thyroid function tests (TFTs), vitamin B12 and folate levels.

Purpose: To rule out reversible causes of cognitive impairment, such as hypothyroidism, vitamin deficiencies, or infections.

c) CT or MRI Brain Scan:

What it examines: Brain imaging to assess for structural abnormalities such as strokes, brain atrophy, or tumours.

Purpose: Used to differentiate between types of dementia (e.g., Alzheimer's disease versus vascular dementia) and to rule out other causes of cognitive decline (e.g., normal pressure hydrocephalus, subdural haematoma).

d) Electrolyte Panel:

What it measures: Sodium, potassium, calcium, and magnesium levels.

Purpose: Electrolyte imbalances, such as hyponatraemia, can cause or exacerbate cognitive impairment.

4. Explanation of Investigations

a) **MMSE and MoCA:**

These are standard cognitive screening tools used to quantify the degree of cognitive impairment and assess memory, language, and executive function. MMSE is widely used but may miss mild cognitive impairment, which the MoCA is more sensitive at detecting.

b) **CT or MRI Brain Scan:**

Imaging helps identify brain atrophy, strokes, or white matter changes suggestive of vascular dementia. In Alzheimer's disease, MRI may show hippocampal atrophy, while CT may be more useful to rule out structural causes such as a tumour.

c) **Blood Tests:**

Screening for treatable conditions such as vitamin B12 deficiency or hypothyroidism is essential, as these are reversible causes of cognitive decline.

5. Diagnostic Criteria for Chronic Cognitive Impairment

Chronic cognitive impairment is diagnosed based on clinical assessment, cognitive testing, and exclusion of reversible causes:

Mild Cognitive Impairment (MCI): Memory complaints confirmed by objective cognitive testing, but daily functioning is largely preserved. MCI can progress to dementia over time.

Dementia: Diagnosed based on significant cognitive impairment that affects multiple domains (e.g., memory, language, executive function) and interferes with daily living.

NICE guidelines recommend early diagnosis through cognitive testing and imaging, particularly when symptoms suggest early-stage dementia.

6. First-Line Therapy According to Guidelines

Management of chronic cognitive impairment focuses on slowing disease progression, managing symptoms, and improving quality of life. Treatment is based on the underlying cause (e.g., Alzheimer's disease, vascular dementia):

a) **Pharmacological Therapy:**

Cholinesterase Inhibitors (e.g., Donepezil, Rivastigmine):

Indication: For mild to moderate Alzheimer's disease.

Mechanism: Increases acetylcholine levels by inhibiting its breakdown, temporarily improving cognition and daily functioning.

Memantine:

Indication: For moderate to severe Alzheimer's disease or when cholinesterase inhibitors are not tolerated.

Mechanism: An NMDA receptor antagonist that modulates glutamate activity, helping to reduce neurotoxicity and improve cognition.

Antidepressants (e.g., SSRIs):

Indication: For patients with coexisting depression or anxiety, which are common in cognitive impairment.

b) Lifestyle and Supportive Therapies:

Cognitive Stimulation Therapy:

Indication: Group-based activities designed to improve cognitive function, memory, and social engagement.

Physical Activity:

Indication: Regular exercise has been shown to slow cognitive decline and improve mood and mobility.

Dietary Management:

Indication: A balanced diet, particularly the Mediterranean diet (rich in fruits, vegetables, and healthy fats), is associated with slower cognitive decline.

Social and Environmental Modifications:

Indication: Modifying the home environment to reduce safety risks (e.g., removing tripping hazards, adding memory aids) and ensuring regular social interaction can improve the quality of life.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Cholinesterase Inhibitors: These should be used with caution in patients with bradycardia or those taking medications that lower heart rate, as they may exacerbate these conditions.

b) Second-Line Therapy:

Antipsychotics (e.g., Risperidone):

Indication: Used only in cases of severe agitation, aggression, or psychosis in dementia, and typically for short durations due to the increased risk of stroke and mortality in elderly patients with dementia.

Referral to Memory Clinics:

Indication: For patients with unclear diagnoses or rapidly progressive cognitive decline, referral to a specialist memory clinic may be required for further assessment and management.

8. Routine Monitoring and Follow-Up

a) **Regular Cognitive Assessments:**

Patients should undergo routine cognitive testing (e.g., every 6-12 months) to monitor disease progression and adjust treatment plans accordingly.

b) **Medication Review:**

Frequent review of medications to assess efficacy and manage potential side effects, particularly with cholinesterase inhibitors and antipsychotics.

c) **Support for Caregivers:**

Caregivers play a critical role in managing chronic cognitive impairment. They should receive regular support and respite care to prevent caregiver burnout.

d) **Advance Care Planning:**

For patients with progressive cognitive impairment, discussions around advance care planning, power of attorney, and end-of-life care should be initiated early.

9. Complications of Chronic Cognitive Impairment

a) **Increased Risk of Falls and Injuries:**

Cognitive impairment can affect balance and judgment, increasing the risk of falls and associated injuries, such as fractures or head trauma.

b) **Malnutrition and Weight Loss:**

Cognitive decline can lead to poor nutrition due to forgetting to eat, loss of appetite, or difficulties with food preparation.

c) **Wandering and Getting Lost:**

Patients with dementia may wander or become disoriented, placing them at risk of injury or exploitation.

d) **Infection Risk:**

Patients with cognitive impairment may neglect personal hygiene or fail to manage chronic conditions, leading to an increased risk of infections such as urinary tract infections or pneumonia.

Summary of Key Points for Chronic Cognitive Impairment

Chronic cognitive impairment encompasses a range of conditions, including mild cognitive impairment (MCI) and dementia, which result in long-term cognitive decline affecting memory, decision-making, and daily functioning.

Diagnosis is based on cognitive assessments (e.g., MMSE, MoCA) and imaging, alongside ruling out reversible causes such as vitamin deficiencies or thyroid dysfunction.

Management focuses on pharmacological treatments (e.g., cholinesterase inhibitors, memantine) and supportive interventions such as cognitive stimulation, physical activity, and environmental modifications.

Regular monitoring, caregiver support, and early advance care planning are essential to managing complications and maintaining quality of life.

35. Delirium (Acute Confusional State)

1. Detailed Definition of Delirium

Delirium, also known as acute confusional state, is a rapid-onset disturbance in attention, awareness, and cognition, often fluctuating in severity throughout the day. It is typically triggered by an underlying medical condition, medications, or environmental changes, and is common in hospitalised elderly patients. Delirium is characterised by:

Hypoactive delirium: Marked by lethargy, inattention, and decreased motor activity.

Hyperactive delirium: Exhibits agitation, restlessness, and hallucinations.

Mixed delirium: Alternates between hypoactive and hyperactive states.

Delirium is a medical emergency, and failure to identify and treat the underlying cause can lead to poor outcomes, including increased mortality, prolonged hospital stays, and long-term cognitive impairment.

2. Common Presenting Complaints and Symptoms

Delirium presents with a variety of symptoms that can fluctuate over time:

a) **Acute Onset and Fluctuating Course:**

Symptoms develop quickly, often within hours or days, and fluctuate throughout the day, with periods of lucidity followed by confusion.

b) **Inattention:**

The patient struggles to focus, maintain attention, or follow instructions.

c) **Disorganised Thinking:**

Thoughts may be fragmented, illogical, or incoherent, with difficulty in reasoning or maintaining a conversation.

d) **Altered Level of Consciousness:**

Patients may fluctuate between being drowsy (hypoactive) and agitated or hypervigilant (hyperactive).

e) **Disorientation:**

Patients may be disoriented to time, place, or even self, often unable to understand their environment.

f) **Hallucinations and Delusions:**

Visual or auditory hallucinations, and delusional beliefs, are more common in hyperactive delirium.

g) Emotional Lability:

Rapid mood swings, anxiety, irritability, or apathy are common in patients with delirium.

h) Reversal of Sleep-Wake Cycle:

Patients may be awake and restless at night, with increased drowsiness during the day.

3. First-Line Investigations

The diagnosis of delirium is clinical, but a thorough assessment is needed to identify the underlying cause. Key investigations include:

a) Cognitive Screening Tools:

Confusion Assessment Method (CAM):

What it measures: Assesses acute onset, inattention, disorganised thinking, and altered consciousness.

Purpose: CAM is a quick, validated tool used to diagnose delirium. It requires the presence of acute onset, inattention, and either disorganised thinking or altered consciousness.

b) Full Blood Count (FBC):

What it measures: Assesses for infection (e.g., raised white blood cell count) or anaemia.

Purpose: Identifies infections, anaemia, or other causes of delirium.

c) Urea and Electrolytes (U&Es):

What they measure: Sodium, potassium, urea, creatinine levels.

Purpose: Detects dehydration, renal failure, or electrolyte imbalances (e.g., hyponatraemia) that may cause delirium.

d) Liver Function Tests (LFTs):

What they measure: Enzyme levels, bilirubin.

Purpose: Assesses for liver disease, which can contribute to hepatic encephalopathy, a common cause of delirium.

e) Glucose Levels:

What it measures: Blood sugar levels.

Purpose: Hypoglycaemia or hyperglycaemia can precipitate delirium.

f) Urinalysis and Urine Culture:

What it measures: Identifies infection or dehydration.

Purpose: Urinary tract infections (UTIs) are a common cause of delirium in the elderly.

g) Chest X-ray:

What it examines: Assesses the lungs for infection, heart failure, or malignancy.

Purpose: Diagnoses pneumonia or other chest infections that can cause delirium.

h) **Electrocardiogram (ECG):**

What it examines: Heart rhythm and electrical activity.

Purpose: Identifies arrhythmias, myocardial infarction, or heart failure, all of which can lead to delirium.

4. Explanation of Investigations

a) **Confusion Assessment Method (CAM):**

A quick, reliable bedside tool that helps diagnose delirium by assessing its four core features: acute onset, fluctuating course, inattention, and either disorganised thinking or altered consciousness.

b) **U&Es and LFTs:**

Electrolyte disturbances (e.g., hyponatraemia) and liver failure can directly contribute to cognitive dysfunction and delirium. Correcting these metabolic abnormalities is key to managing delirium.

c) **Urinalysis:**

In elderly patients, UTIs are a frequent, often asymptomatic, cause of delirium. Urine tests help confirm infection.

5. Diagnostic Criteria for Delirium

Delirium is diagnosed based on the following criteria (per **DSM-5** and **CAM**):

Acute onset and fluctuating course: Rapid onset of cognitive disturbance that waxes and wanes.

Inattention: Inability to focus, maintain, or shift attention.

Disorganised thinking: Illogical, incoherent thoughts.

Altered level of consciousness: Ranges from lethargy to hyperactivity.

NICE guidelines stress the importance of early recognition and diagnosis, particularly in high-risk populations such as the elderly or those with pre-existing cognitive impairments.

6. First-Line Therapy According to Guidelines

Management of delirium is primarily supportive, with treatment directed at addressing the underlying cause. Key interventions include:

a) **Non-Pharmacological Interventions:**

Reorientation and Cognitive Support:

Action: Provide frequent reorientation, use clocks, calendars, and familiar objects to help maintain awareness.

Outcome: Helps reduce confusion and anxiety.

Environmental Modifications:

Action: Ensure a well-lit, quiet environment, reduce noise, and provide glasses or hearing aids if needed.

Outcome: Reduces sensory overload and environmental triggers that exacerbate delirium.

Family Involvement:

Action: Encourage family presence, as familiar faces can help reassure and reorient the patient.

Outcome: Helps reduce agitation and improves cooperation.

Sleep-Wake Cycle Management:

Action: Establish a routine with day-night cues (e.g., lights on during the day, dark at night).

Outcome: Minimises sleep disturbances and reduces delirium severity.

b) Treat the Underlying Cause:

Infection:

Action: Administer appropriate antibiotics for UTIs, pneumonia, or other infections.

Outcome: Resolves the underlying infection causing delirium.

Dehydration:

Action: Rehydrate the patient with intravenous fluids.

Outcome: Corrects dehydration and resolves electrolyte imbalances.

Medication Review:

Action: Review and stop unnecessary medications, particularly sedatives, opioids, and anticholinergic drugs.

Outcome: Reduces drug-induced delirium.

c) Pharmacological Treatment (only if non-pharmacological methods fail):

Haloperidol (or alternative antipsychotics):

Indication: For severe agitation or hallucinations that pose a risk to the patient or others.

Dose: Start with low doses (0.5–1 mg orally/IM) and titrate cautiously.

Mechanism: Blocks dopamine receptors, reducing agitation and psychosis.

Caution: Avoid in patients with Parkinson's disease or Lewy body dementia due to the risk of worsening motor symptoms.

Risperidone or Quetiapine:

Indication: Used as alternatives to haloperidol in patients where sedation is necessary but with fewer extrapyramidal side effects.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Haloperidol: Should be avoided in patients with Parkinson's disease, Lewy body dementia, or QT prolongation, as it can exacerbate motor symptoms and increase the risk of arrhythmias.

b) Second-Line Therapy:

Risperidone or Quetiapine:

Indication: Used in patients who cannot tolerate haloperidol due to the risk of motor symptoms or arrhythmias. Lower side effect profile for sedation and agitation.

Benzodiazepines:

Indication: May be considered in alcohol withdrawal delirium but should generally be avoided in most other forms of delirium due to the risk of worsening confusion.

8. Routine Monitoring and Follow-Up

a) Cognitive Monitoring:

Patients should be assessed daily for changes in mental status, using tools like the CAM to monitor resolution of delirium.

b) Vital Signs and Bloodwork:

Regular monitoring of vital signs, hydration status, and electrolyte levels to ensure the underlying cause of delirium is being adequately treated.

c) Medication Review:

Frequent reviews to stop or adjust medications that may have contributed to the delirium, such as sedatives or anticholinergics.

d) Follow-up Post-Discharge:

Patients should be reassessed after discharge, as delirium increases the risk of long-term cognitive impairment and recurrent hospitalisations.

9. Complications of Delirium

a) Prolonged Hospital Stay:

Delirium is associated with longer hospital admissions, increasing the risk of hospital-acquired infections and functional decline.

b) Increased Mortality:

Patients with delirium have higher mortality rates, particularly if the underlying cause is severe or left untreated.

c) Increased Risk of Falls and Injury:

Agitation and confusion can lead to falls and injuries, particularly in hyperactive delirium.

d) **Long-Term Cognitive Decline:**

Delirium increases the risk of long-term cognitive impairment, including the progression to dementia.

Summary of Key Points for Delirium (Acute Confusional State)

Delirium is an acute confusional state with fluctuating cognitive and attentional deficits, most commonly seen in the elderly.

Diagnosis is based on clinical assessment using tools such as the **Confusion Assessment Method (CAM)** and is aimed at identifying the underlying cause.

Management involves treating the underlying cause, providing supportive care, and using antipsychotics (e.g., haloperidol) only when non-pharmacological interventions fail.

Regular monitoring and follow-up are essential, as delirium can lead to poor outcomes, including increased mortality and long-term cognitive decline.

36. Dementia

1. Detailed Definition of Dementia

Dementia is a chronic, progressive condition characterised by the decline in cognitive function severe enough to interfere with daily life and independence. It involves impairment in memory, language, problem-solving, and other cognitive skills, often accompanied by behavioural and psychological symptoms. Dementia is an umbrella term for various conditions that cause cognitive decline, including:

Alzheimer's Disease: The most common form of dementia, associated with amyloid plaques and tau tangles in the brain.

Vascular Dementia: Caused by reduced blood flow to the brain, often following strokes or small vessel disease.

Lewy Body Dementia: Characterised by the presence of Lewy bodies in brain cells, leading to cognitive impairment and motor symptoms.

Frontotemporal Dementia (FTD): Involves atrophy of the frontal and temporal lobes, leading to personality changes and language impairment.

Dementia is usually progressive, meaning it worsens over time, and there is currently no cure, though treatments can help manage symptoms.

2. Common Presenting Complaints and Symptoms

Dementia presents with a range of cognitive, psychological, and functional symptoms that vary depending on the type and stage of the disease:

a) **Memory Loss:**

Difficulty recalling recent events, appointments, or conversations (short-term memory loss), while long-term memories may remain intact in the early stages.

b) Disorientation:

Confusion about time, place, and sometimes even familiar people. Patients may become lost in familiar environments.

c) Language Problems:

Difficulty finding the right words, following conversations, or understanding written or spoken language.

d) Impaired Judgment and Decision-Making:

Poor decision-making, inability to solve problems, or difficulty managing finances, medications, or household tasks.

e) Personality and Behavioural Changes:

Depression, anxiety, irritability, aggression, apathy, or social withdrawal. Hallucinations and delusions are common, particularly in Lewy body dementia.

f) Difficulty with Activities of Daily Living (ADLs):

Problems performing tasks such as dressing, bathing, cooking, and managing medications as dementia progresses.

g) Sleep Disturbances:

Sleep-wake cycle disturbances, including insomnia or excessive daytime sleepiness, are common in dementia.

h) Motor Symptoms (in certain types of dementia):

In Lewy body dementia and Parkinson's disease dementia, patients may experience tremors, muscle stiffness, or other movement disorders.

3. First-Line Investigations

A diagnosis of dementia is clinical but supported by cognitive testing and investigations to rule out other causes of cognitive decline:

a) Cognitive Screening Tools:

Mini-Mental State Examination (MMSE):

What it measures: Assesses orientation, recall, attention, calculation, language, and visuospatial abilities.

Purpose: Commonly used to detect cognitive impairment, although it may miss mild dementia.

Montreal Cognitive Assessment (MoCA):

What it measures: More sensitive for mild cognitive impairment, it assesses memory, attention, executive function, and visuospatial abilities.

b) Blood Tests:

What they measure: Full blood count (FBC), urea and electrolytes (U&Es), thyroid function tests (TFTs), vitamin B12 and folate levels.

Purpose: To rule out reversible causes of cognitive impairment, such as hypothyroidism, vitamin B12 deficiency, or electrolyte imbalances.

c) CT or MRI Brain Scan:

What it examines: Provides imaging of the brain to assess for structural abnormalities.

Purpose: Used to identify brain atrophy, white matter changes (suggestive of vascular dementia), or other abnormalities such as tumours or subdural haematomas.

d) Electrolyte Panel:

What it measures: Levels of sodium, potassium, calcium, and magnesium.

Purpose: Identifies metabolic disturbances that can contribute to cognitive impairment.

e) Positron Emission Tomography (PET) or Single Photon Emission Computed Tomography (SPECT) (specialist test):

What it examines: Assesses metabolic activity in the brain.

Purpose: Can be used to detect amyloid deposits in Alzheimer's disease or differentiate types of dementia.

4. Explanation of Investigations

a) MMSE and MoCA:

These cognitive assessments help to quantify the degree of cognitive impairment and monitor progression over time. MMSE is commonly used, but MoCA is more sensitive for detecting early-stage dementia.

b) CT or MRI Brain Scan:

CT or MRI helps differentiate between types of dementia. In Alzheimer's disease, MRI may show hippocampal atrophy, while in vascular dementia, multiple infarcts or white matter changes may be evident.

c) Blood Tests:

These tests are crucial for ruling out reversible causes of cognitive decline, such as vitamin B12 deficiency, hypothyroidism, or infections.

5. Diagnostic Criteria for Dementia

The diagnosis of dementia is based on clinical criteria, supported by cognitive testing and the exclusion of reversible causes. According to the **DSM-5** criteria, dementia (also known as **Major Neurocognitive Disorder**) is diagnosed when there is:

Significant cognitive decline in one or more cognitive domains (e.g., memory, language, executive function, visuospatial skills).

The cognitive decline interferes with independence in everyday activities.

The cognitive deficits are not due to delirium or another mental disorder.

NICE guidelines recommend early diagnosis to facilitate treatment and care planning, especially for those with progressive conditions like Alzheimer's disease.

6. First-Line Therapy According to Guidelines

Although there is no cure for dementia, several treatments aim to slow disease progression, manage symptoms, and improve quality of life:

a) Pharmacological Treatment:

Cholinesterase Inhibitors (e.g., Donepezil, Rivastigmine, Galantamine):

Indication: For mild to moderate Alzheimer's disease, Lewy body dementia, and Parkinson's disease dementia.

Mechanism: Increases acetylcholine levels by inhibiting its breakdown, improving memory and cognitive function.

Memantine:

Indication: For moderate to severe Alzheimer's disease or in combination with cholinesterase inhibitors.

Mechanism: An NMDA receptor antagonist that regulates glutamate activity, helping reduce neurotoxicity and slow cognitive decline.

Antidepressants (e.g., SSRIs):

Indication: For depression or anxiety, which are common comorbidities in dementia patients.

Antipsychotics (e.g., Risperidone) (used sparingly):

Indication: For severe behavioural disturbances (e.g., aggression, hallucinations), but only after non-pharmacological approaches have failed. Used cautiously due to the risk of stroke and mortality in elderly patients.

b) Non-Pharmacological Interventions:

Cognitive Stimulation Therapy (CST):

Indication: Group-based therapy designed to improve cognition, memory, and social interaction.

Physical Activity:

Indication: Regular exercise can help slow cognitive decline and improve mood and overall function.

Dietary Interventions:

Indication: A healthy diet, particularly the Mediterranean diet, has been associated with slower cognitive decline.

Social and Environmental Modifications:

Indication: Creating a dementia-friendly environment with safety modifications (e.g., reducing tripping hazards) and memory aids (e.g., labels, clocks) can improve daily functioning and safety.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Cholinesterase Inhibitors: These drugs should be used with caution in patients with bradycardia or heart block, as they can exacerbate these conditions.

b) Second-Line Therapy:

Referral to Memory Clinics:

Indication: For patients with uncertain diagnoses or rapidly progressive dementia, referral to a memory clinic for specialist assessment may be necessary.

Antipsychotics (Risperidone, Quetiapine, Olanzapine):

Indication: These are considered second-line treatments for severe agitation, hallucinations, or delusions, particularly when non-pharmacological methods have failed.

8. Routine Monitoring and Follow-Up

a) Cognitive Monitoring:

Patients should be regularly assessed with cognitive tools (e.g., MMSE, MoCA) to monitor progression and adjust treatment accordingly.

b) Medication Review:

Ongoing review of medications, particularly cholinesterase inhibitors and memantine, to ensure they are effective and well-tolerated.

c) Caregiver Support:

Providing regular support and resources for caregivers to manage stress and prevent burnout. This includes respite care, support groups, and education.

d) Advance Care Planning:

As dementia progresses, discussions around advance care planning, power of attorney, and end-of-life care should be initiated early.

9. Complications of Dementia

a) Increased Risk of Falls:

Cognitive decline can affect balance and judgment, increasing the risk of falls and subsequent fractures.

b) Malnutrition:

Difficulty with feeding or loss of appetite can lead to malnutrition and weight loss as the disease progresses.

c) Wandering and Getting Lost:

Patients with dementia may wander or become lost, placing them at risk of injury or exploitation.

d) Infections:

Neglect of personal hygiene or difficulties managing chronic conditions can lead to infections such as pneumonia or urinary tract infections.

e) Depression and Anxiety:

Psychological symptoms are common and can exacerbate cognitive decline.

Summary of Key Points for Dementia

Dementia is a progressive cognitive disorder that affects memory, language, executive function, and daily living activities.

Diagnosis is clinical, supported by cognitive testing (MMSE, MoCA) and imaging (CT or MRI), alongside exclusion of reversible causes of cognitive impairment.

Management focuses on pharmacological treatments (cholinesterase inhibitors, memantine) and non-pharmacological interventions (cognitive stimulation, physical activity) to slow disease progression and improve quality of life.

Regular monitoring, caregiver support, and early advance care planning are essential for managing complications and long-term care needs.

37. Dizziness

1. Detailed Definition of Dizziness

Dizziness is a broad term used to describe a range of sensations, such as feeling lightheaded, unsteady, faint, or a spinning sensation (vertigo). It can be caused by various conditions affecting the inner ear, cardiovascular system, or neurological function. Dizziness is particularly common in elderly patients and is often multifactorial in origin. It is important to distinguish between:

Vertigo: The false sensation that you or your surroundings are spinning or moving.

Presyncope: A feeling of near fainting, often due to decreased blood flow to the brain.

Disequilibrium: A sensation of imbalance or unsteadiness when walking, often related to musculoskeletal or neurological conditions.

2. Common Presenting Complaints and Symptoms

Patients experiencing dizziness may describe it in different ways depending on the underlying cause:

a) Vertigo:

A spinning sensation, often worsened by head movements.

Nausea and vomiting may accompany vertigo.

Patients may report imbalance or difficulty walking.

b) Presyncope (Feeling Faint or Lightheaded):

A sensation of near-fainting, especially when standing up suddenly.

May be associated with visual disturbances, sweating, or palpitations.

Often linked to low blood pressure, dehydration, or cardiac conditions.

c) Disequilibrium:

Feeling unsteady or off-balance, particularly while walking.

Patients may feel at risk of falling and may hold onto objects for support.

This is often seen in elderly patients with musculoskeletal or neurological conditions.

d) Generalised Dizziness:

A vague sensation of being off-balance or "floating" that does not fit neatly into the categories of vertigo, presyncope, or disequilibrium.

May be due to anxiety, hyperventilation, or medication side effects.

3. First-Line Investigations

The investigation of dizziness depends on the suspected cause, but key assessments include:

a) History and Physical Examination:

What it examines: A detailed history to determine the type of dizziness (vertigo, presyncope, disequilibrium) and possible triggers (e.g., head movements, standing up, or stress).

Purpose: Helps to differentiate between different types of dizziness and identify underlying causes.

b) Orthostatic Blood Pressure Measurement:

What it measures: Blood pressure is measured while the patient is lying down, then again after standing up.

Purpose: Used to identify orthostatic hypotension (a drop in blood pressure on standing), which can cause dizziness.

c) Dix-Hallpike Manoeuvre (for suspected benign paroxysmal positional vertigo – BPPV):

What it measures: Assesses for vertigo and nystagmus triggered by positional changes.

Purpose: Confirms the diagnosis of BPPV, a common cause of vertigo.

d) **Electrocardiogram (ECG):**

What it examines: Assesses heart rhythm and electrical activity.

Purpose: Detects arrhythmias or heart block that could cause dizziness due to reduced blood flow to the brain.

e) **Full Blood Count (FBC) and Urea & Electrolytes (U&Es):**

What they measure: Red blood cell levels, electrolytes, and hydration status.

Purpose: Identifies anaemia or electrolyte imbalances, both of which can contribute to dizziness.

f) **Audiometry and Vestibular Function Testing** (for vertigo):

What it examines: Assesses hearing and vestibular (balance) function.

Purpose: Used to evaluate inner ear function, particularly in cases of persistent vertigo or suspected Meniere's disease.

4. Explanation of Investigations

a) **Dix-Hallpike Manoeuvre:**

A bedside test used to diagnose BPPV, a common cause of vertigo. The patient's head is moved into different positions to provoke vertigo and nystagmus, which are typical of this condition.

b) **Orthostatic Blood Pressure Measurement:**

This test helps diagnose orthostatic hypotension, which occurs when blood pressure drops significantly upon standing, leading to dizziness. A drop of 20 mmHg in systolic BP or 10 mmHg in diastolic BP is diagnostic.

c) **ECG:**

An ECG is useful in detecting heart-related causes of dizziness, such as arrhythmias or heart block, which reduce cerebral blood flow and lead to presyncope.

5. Diagnostic Criteria for Dizziness

The diagnostic criteria depend on the underlying cause:

Benign Paroxysmal Positional Vertigo (BPPV): Diagnosed based on positive **Dix-Hallpike manoeuvre** with characteristic vertigo and nystagmus.

Orthostatic Hypotension: Defined as a drop in systolic blood pressure ≥ 20 mmHg or diastolic blood pressure ≥ 10 mmHg upon standing.

Meniere's Disease: Diagnosed based on a combination of vertigo, fluctuating hearing loss, tinnitus, and a feeling of fullness in the ear.

Cardiac Syncope: Diagnosed through ECG, demonstrating arrhythmias or heart block, often accompanied by presyncope or syncope.

NICE guidelines recommend thorough evaluation, particularly in elderly patients, to identify treatable causes and reduce the risk of falls and injury.

6. First-Line Therapy According to Guidelines

Management of dizziness is directed at treating the underlying cause:

a) Vertigo (BPPV):

Epley Manoeuvre:

Indication: Used to treat BPPV.

Mechanism: Series of head movements that reposition dislodged otoliths in the inner ear.

Outcome: Relieves vertigo by resolving the underlying mechanical disruption in the inner ear.

Vestibular Rehabilitation:

Indication: For persistent vertigo due to vestibular dysfunction.

Mechanism: A physical therapy programme that improves balance and reduces vertigo by retraining the brain's response to vestibular signals.

Medications (e.g., Betahistine):

Indication: Used for Meniere's disease or severe vertigo.

Mechanism: Reduces inner ear fluid pressure, alleviating vertigo and associated symptoms.

b) Presyncope (Orthostatic Hypotension):

Increase Fluid and Salt Intake:

Indication: To manage dehydration or orthostatic hypotension.

Mechanism: Helps increase blood volume, preventing drops in blood pressure upon standing.

Medication Review:

Indication: Adjust or stop medications that may contribute to hypotension (e.g., diuretics, antihypertensives).

Compression Stockings:

Indication: To improve venous return and reduce orthostatic hypotension.

Mechanism: Helps prevent blood pooling in the legs, maintaining blood pressure on standing.

c) Cardiac Causes (Arrhythmias):

Pacemaker:

Indication: For bradycardia or heart block causing dizziness or syncope.

Mechanism: Regulates heart rate to prevent dizziness due to slow heart rhythms.

Antiarrhythmic Medications:

Indication: For tachyarrhythmias causing presyncope.

Mechanism: Controls the heart rhythm to prevent dizziness caused by rapid heart rates.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Medications for Vertigo: Long-term use of vestibular suppressants (e.g., antihistamines, benzodiazepines) should be avoided as they can slow recovery from vestibular disorders by preventing central compensation.

b) Second-Line Therapy:

Fludrocortisone:

Indication: For refractory orthostatic hypotension.

Mechanism: Increases blood volume by promoting sodium retention, thus helping to stabilise blood pressure.

Midodrine:

Indication: For severe orthostatic hypotension.

Mechanism: A vasoconstrictor that raises blood pressure, preventing dizziness caused by hypotension.

8. Routine Monitoring and Follow-Up

a) Regular Blood Pressure Monitoring:

Patients with orthostatic hypotension should have their blood pressure monitored regularly, particularly when standing, to assess treatment efficacy.

b) Cognitive and Balance Assessments:

In elderly patients, cognitive function and balance should be assessed regularly to reduce fall risk and prevent complications.

c) Medication Review:

Patients on medications for dizziness or vertigo should have regular reviews to assess for side effects or the need for adjustments.

9. Complications of Dizziness

a) Falls and Injuries:

Dizziness increases the risk of falls, especially in elderly patients, which can lead to fractures, head trauma, or other injuries.

b) Depression and Anxiety:

Chronic dizziness can result in anxiety or depression, particularly if the cause is not identified or properly managed.

c) **Reduced Quality of Life:**

Persistent dizziness can lead to fear of falling, social withdrawal, and limitations in daily activities, severely impacting quality of life.

Summary of Key Points for Dizziness

Dizziness is a common symptom in elderly patients, with different subtypes such as vertigo, presyncope, and disequilibrium.

Diagnosis relies on a detailed history, physical examination, and targeted tests (e.g., Dix-Hallpike manoeuvre, orthostatic blood pressure measurements) to identify the underlying cause.

Management is tailored to the cause, with treatments like the Epley manoeuvre for BPPV, increased fluids for orthostatic hypotension, and antiarrhythmic medications for cardiac causes.

Regular monitoring and multidisciplinary follow-up are crucial, especially in elderly patients, to prevent falls and improve overall outcomes.

38. Elder Abuse

1. Detailed Definition of Elder Abuse

Elder abuse refers to intentional or negligent acts by a caregiver or other person that cause harm or create a serious risk of harm to a vulnerable older adult. It can occur in various settings, including at home, in assisted living facilities, or in nursing homes. Elder abuse may be physical, emotional, sexual, financial, or neglectful. It is often underreported due to factors such as the victim's dependency on the abuser, fear of retaliation, or cognitive impairments that hinder communication.

Types of elder abuse include:

Physical Abuse: Inflicting physical pain or injury (e.g., hitting, slapping, or using restraints).

Emotional or Psychological Abuse: Inflicting mental anguish (e.g., verbal abuse, humiliation, intimidation).

Sexual Abuse: Non-consensual sexual contact of any kind.

Financial Exploitation: Illegally or improperly using an elder's money, assets, or property.

Neglect: Failing to provide necessary care, such as food, shelter, health care, or protection from harm.

2. Common Presenting Complaints and Symptoms

Elder abuse can manifest through various signs and symptoms, which may be subtle or overlooked. These include:

a) Physical Signs:

Unexplained bruises, burns, cuts, or fractures.

Frequent hospital visits for injuries.

Injuries in different stages of healing, suggesting repeated harm.

Restraint marks on the wrists or ankles.

b) Emotional and Behavioural Changes:

Fear, anxiety, or depression, particularly in the presence of certain caregivers.

Withdrawal from social interactions or previously enjoyed activities.

Sudden changes in behaviour, such as becoming more aggressive or agitated.

Unusual or sudden changes in personality, such as increased confusion or apathy.

c) Financial Red Flags:

Unexplained or sudden changes in financial situations, such as large withdrawals, unusual banking activities, or sudden changes to wills or property titles.

The elder is unaware of their financial situation or unable to explain it.

Unpaid bills despite having sufficient financial resources.

d) Neglect Indicators:

Poor personal hygiene (e.g., unwashed clothing, body odour, unkempt appearance).

Malnutrition, dehydration, or pressure ulcers due to lack of care.

Untreated medical conditions or missed medical appointments.

Unsafe living conditions, such as poor sanitation, inadequate heating, or cluttered environments that pose fall risks.

e) Sexual Abuse Signs:

Bruising or injuries around the genital area.

Unexplained sexually transmitted infections (STIs).

Difficulty sitting or walking.

Reluctance to be touched or examined.

3. First-Line Investigations

The assessment of suspected elder abuse requires careful investigation, often involving a multidisciplinary team. Key steps include:

a) History and Physical Examination:

What it examines: A detailed medical history and physical examination to assess for signs of abuse, neglect, or injury.

Purpose: Identifies any unexplained injuries or patterns of harm. The history should be taken separately from the caregiver to ensure the patient can speak freely.

b) Psychological Assessment:

What it measures: Assesses the mental health and emotional state of the elder.

Purpose: Screens for signs of anxiety, depression, or post-traumatic stress disorder (PTSD), which may indicate psychological abuse or neglect.

c) Cognitive Assessment:

What it measures: Assesses cognitive function using tools such as the Mini-Mental State Examination (MMSE).

Purpose: Determines whether cognitive impairment might limit the elder's ability to report abuse or make decisions about their care.

d) Blood Tests (e.g., FBC, U&Es, Nutritional Markers):

What they measure: Assess for signs of malnutrition, dehydration, or untreated medical conditions.

Purpose: Identifies neglect, such as dehydration or malnutrition, especially in patients with limited mobility or severe health conditions.

e) Documentation of Injuries:

What it examines: Detailed recording of any physical injuries, including their size, shape, and location.

Purpose: Provides essential evidence of physical abuse, with photographs taken if possible.

f) Financial Review:

What it examines: A review of financial records, including bank statements, property records, and bills.

Purpose: Detects unusual transactions or financial exploitation, such as sudden large withdrawals or changes to financial documents.

4. Explanation of Investigations

a) History and Physical Examination:

The elder should be interviewed in private, without the caregiver present, to allow them to express concerns freely. The examination should focus on any injuries or signs of neglect. All findings should be thoroughly documented.

b) Psychological and Cognitive Assessments:

These assessments are important for understanding the elder's mental state and any cognitive limitations that might affect their ability to communicate about the abuse or make decisions about their care.

c) Documentation of Injuries:

Detailed and accurate documentation of physical injuries is essential for legal proceedings and

protective measures. This may include photographing injuries (with the elder's consent) to provide objective evidence of abuse.

5. Diagnostic Criteria for Elder Abuse

There is no single diagnostic test for elder abuse, but it is diagnosed based on a combination of physical, psychological, and social signs. Important indicators include:

Physical Signs: Unexplained injuries, particularly if they are inconsistent with the elder's explanation or are in different stages of healing.

Psychological Signs: Anxiety, depression, or fearfulness, particularly when certain caregivers are present.

Neglect Indicators: Malnutrition, dehydration, poor hygiene, untreated medical conditions, or an unsafe living environment.

Financial Red Flags: Unexplained changes in financial status, large withdrawals, or sudden changes to legal documents such as wills.

NICE guidelines recommend a high index of suspicion for elder abuse in vulnerable populations and emphasise the need for multidisciplinary assessment and safeguarding.

6. First-Line Therapy According to Guidelines

The management of elder abuse involves immediate protective measures, reporting to appropriate authorities, and addressing the elder's physical and emotional needs:

a) Safeguarding and Protection:

Action: Report suspected elder abuse to social services or adult safeguarding teams.

Outcome: Ensures the elder's immediate safety and initiates an investigation by the relevant authorities.

b) Medical Care for Injuries or Neglect:

Action: Treat any physical injuries, malnutrition, dehydration, or infections.

Outcome: Addresses the immediate physical health concerns resulting from abuse or neglect.

c) Social Worker Involvement:

Action: A social worker should be involved to assess the elder's living situation and arrange for necessary support, such as alternative accommodation or caregiving arrangements.

Outcome: Protects the elder from further harm and ensures they are placed in a safe, supportive environment.

d) Psychological Support:

Action: Referral to a psychologist or counsellor for mental health support, particularly if the elder is experiencing anxiety, depression, or PTSD.

Outcome: Helps the elder cope with the emotional trauma of abuse and promotes recovery.

e) **Legal and Financial Protection:**

Action: In cases of financial exploitation, referral to legal services or financial protection teams may be necessary to recover stolen assets or protect the elder from further exploitation.

Outcome: Prevents further financial abuse and ensures the elder's assets are safeguarded.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Inaction: Failing to act upon suspected elder abuse can leave the elder at continued risk of harm.

Returning the Elder to the Same Environment: Returning the elder to an unsafe environment without protective measures in place can result in further abuse or neglect.

b) **Second-Line Therapy:**

Placement in Alternative Care Facilities:

Indication: If the elder cannot safely remain at home, even with support, they may need to be placed in a nursing home, care facility, or with a trusted family member.

Counselling for Caregivers:

Indication: In some cases, caregivers may benefit from counselling or respite care, particularly if the abuse results from caregiver stress or burnout.

8. Routine Monitoring and Follow-Up

a) **Regular Social Care Assessments:**

Following the identification of abuse, regular follow-up assessments by social workers are essential to ensure the elder remains in a safe environment and is receiving appropriate care.

b) **Medical Monitoring:**

Routine medical follow-up is important for monitoring physical and psychological recovery from abuse, particularly in cases of neglect or malnutrition.

c) **Psychological Support:**

Ongoing mental health support should be provided to address the emotional effects of the abuse and prevent long-term psychological harm.

9. Complications of Elder Abuse

a) **Increased Morbidity and Mortality:**

Elder abuse is associated with higher rates of hospitalisation, physical injuries, and increased mortality.

b) Chronic Mental Health Issues:

Victims of elder abuse often experience long-term psychological consequences, including depression, anxiety, and post-traumatic stress disorder (PTSD).

c) Loss of Independence:

Elder abuse, particularly neglect, can lead to worsening physical or cognitive function, resulting in the need for long-term care or loss of independence.

d) Financial Ruin:

In cases of financial exploitation, elders may lose their life savings or property, leading to long-term financial instability.

Summary of Key Points for Elder Abuse

Elder abuse is a serious and often underreported problem, characterised by physical, emotional, financial, or sexual harm to a vulnerable older person.

Diagnosis relies on recognising key signs such as unexplained injuries, neglect, financial exploitation, or psychological distress.

Management involves immediate safeguarding, medical care, psychological support, and legal intervention to protect the elder and prevent further harm.

Regular monitoring, social services involvement, and mental health support are essential for recovery and preventing recurrence.

39. Faecal Incontinence

1. Detailed Definition of Faecal Incontinence

Faecal incontinence is the involuntary loss of bowel control, leading to the unintentional passing of stools or gas. It ranges from mild soiling of undergarments to complete loss of control over bowel movements. Faecal incontinence is more common in elderly populations due to age-related changes in bowel function, muscle weakness, or neurological conditions. It can significantly impact quality of life, causing embarrassment, social isolation, and anxiety.

Types of faecal incontinence include:

Urge incontinence: The sudden, intense urge to defecate, followed by an inability to control the bowel movement.

Passive incontinence: The involuntary loss of stool without awareness, often due to weak sphincter muscles or reduced rectal sensation.

Overflow incontinence: Occurs when the rectum is full and leaks stool due to chronic constipation or impaction.

2. Common Presenting Complaints and Symptoms

Patients with faecal incontinence may present with:

a) Involuntary Passage of Stool:

Uncontrolled leakage of stool, which may range from small smears on undergarments to complete bowel evacuation.

b) Urgency:

A sudden, strong urge to defecate, often with little time to reach a toilet.

c) Soiling and Staining of Clothing:

Stool leakage that results in soiling of clothes or bed linens, leading to hygiene concerns and potential skin breakdown.

d) Flatulence or Mucus Discharge:

Unintentional release of gas or mucus along with stool.

e) Constipation or Overflow:

Difficulty passing stools, alternating with episodes of loose stools, may suggest overflow incontinence due to faecal impaction.

f) Perianal Discomfort or Skin Irritation:

Skin irritation, rashes, or breakdown around the anus due to frequent stool leakage.

3. First-Line Investigations

To diagnose faecal incontinence and identify its underlying cause, a combination of clinical history, physical examination, and investigations is needed:

a) History and Physical Examination:

What it examines: The history should assess stool consistency, frequency, triggers (e.g., urgency, bowel habits), and any associated symptoms such as constipation or rectal pain. Physical examination focuses on the perianal area for signs of skin irritation, and a digital rectal examination assesses anal tone, rectal masses, or faecal impaction.

Purpose: Helps identify possible causes, such as sphincter weakness, rectal pathology, or neurological conditions.

b) Stool Diary:

What it measures: Patients are asked to record stool frequency, consistency (using the Bristol Stool Chart), and episodes of incontinence.

Purpose: Provides insight into bowel patterns and helps identify contributing factors such as dietary habits or medication use.

c) Anorectal Manometry:

What it measures: Assesses the pressure of the anal sphincters and rectal sensitivity to distension.

Purpose: Used to evaluate sphincter strength, rectal sensation, and reflexes, especially in cases of neurological causes of faecal incontinence.

d) Endoanal Ultrasound:

What it examines: Imaging of the anal sphincters.

Purpose: Detects structural damage to the internal or external anal sphincters, commonly seen after childbirth or pelvic surgeries.

e) Proctosigmoidoscopy or Colonoscopy:

What it examines: Visualises the rectum and colon to assess for inflammatory bowel disease, tumours, strictures, or other pathologies.

Purpose: Used when there are red flags such as rectal bleeding, unexplained weight loss, or changes in bowel habits.

f) Defaecography:

What it measures: A specialised imaging study that evaluates the process of defecation.

Purpose: Helps assess pelvic floor function and detect structural abnormalities like rectal prolapse.

4. Explanation of Investigations

a) Anorectal Manometry:

This test measures the function of the rectal and anal muscles and nerves. It helps determine if the sphincters are weak or if there is impaired rectal sensation, both of which can contribute to faecal incontinence.

b) Endoanal Ultrasound:

An ultrasound probe is inserted into the rectum to create images of the anal sphincters. This test is useful for detecting tears or thinning of the sphincter muscles, which may be caused by childbirth, surgery, or trauma.

c) Defaecography:

This imaging test shows how well the pelvic floor muscles and rectum function during defecation. It helps identify conditions like rectocele or rectal prolapse, which can lead to incontinence.

5. Diagnostic Criteria for Faecal Incontinence

Faecal incontinence is diagnosed based on clinical history, physical examination, and appropriate investigations. Diagnostic criteria include:

Involuntary loss of stool: At least one episode of involuntary stool leakage, either with or without awareness.

Chronicity: The condition is usually considered chronic if it occurs at least once a month for three months or more.

Underlying cause: Diagnosis is confirmed once the underlying cause is identified, whether it be muscle weakness, rectal dysfunction, neurological impairment, or other pathology.

According to **NICE guidelines**, a comprehensive assessment, including identification of contributing factors (e.g., constipation, muscle weakness, nerve damage), is critical for appropriate management.

6. First-Line Therapy According to Guidelines

Treatment of faecal incontinence depends on the underlying cause and severity. First-line treatments typically focus on conservative management and behavioural modifications:

a) Lifestyle Modifications:

Dietary Changes:

Action: Increase fibre intake (e.g., psyllium or dietary fibre supplements) to regulate stool consistency.

Outcome: Helps reduce episodes of incontinence by bulking up stool, making it easier to control.

Fluid Management:

Action: Ensure adequate fluid intake to prevent constipation while avoiding excessive fluid consumption that may worsen incontinence.

b) Bowel Retraining:

Action: Encourage the patient to establish a regular toileting schedule (e.g., after meals) to train the bowel to empty at specific times.

Outcome: Helps regulate bowel movements and reduce incontinence episodes.

c) Pelvic Floor Exercises (Kegel Exercises):

Action: Strengthen the muscles of the pelvic floor and anal sphincters through regular contraction exercises.

Outcome: Improves muscle tone and control, reducing incontinence.

d) Medications:

Antidiarrhoeals (e.g., Loperamide):

Indication: Used to reduce stool frequency and increase stool consistency in patients with loose stools or diarrhoea-associated incontinence.

Mechanism: Slows intestinal transit and increases absorption of fluids from the bowel.

Stool Softeners (e.g., Docusate Sodium):

Indication: For patients with constipation or hard stools that contribute to overflow incontinence.

Mechanism: Softens stool, making it easier to pass and preventing faecal impaction.

e) **Skin Care:**

Action: Apply barrier creams and maintain good hygiene to protect the skin from irritation caused by frequent stool leakage.

Outcome: Prevents skin breakdown, rashes, and infections in the perianal area.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Antidiarrhoeals: Should be used with caution in patients with constipation or bowel obstruction, as these can worsen the condition.

b) **Second-Line Therapy:**

Biofeedback Therapy:

Indication: For patients who fail conservative measures, biofeedback can be used to improve control over pelvic floor muscles and sphincters.

Mechanism: A therapist uses sensors to help the patient gain better awareness and control over their bowel muscles.

Surgical Options:

Sphincteroplasty: Used to repair a damaged anal sphincter.

Sacral Nerve Stimulation: A device is implanted to stimulate the nerves controlling bowel movements, improving continence.

Stoma Formation: In severe cases, a colostomy may be necessary to divert stool away from the rectum, preventing incontinence.

8. Routine Monitoring and Follow-Up

a) **Bowel Diary:**

Patients should keep a regular bowel diary to track stool consistency, frequency of incontinence, and progress with treatment.

b) **Pelvic Floor Function:**

Regular assessment of pelvic floor function through physical examination or manometry should be performed to assess the effectiveness of pelvic floor exercises or biofeedback therapy.

c) **Medication Review:**

Patients using medications like loperamide or stool softeners should have regular reviews to ensure they are achieving the desired effect without side effects.

9. Complications of Faecal Incontinence

a) Skin Breakdown and Infections:

Frequent soiling can lead to perianal skin irritation, breakdown, or infections such as fungal dermatitis.

b) Psychological Impact:

Faecal incontinence can lead to embarrassment, social isolation, anxiety, and depression due to its impact on personal hygiene and dignity.

c) Dehydration and Malnutrition:

Patients with diarrhoea-associated incontinence may become dehydrated or malnourished if they restrict fluid and food intake to avoid incontinence episodes.

Summary of Key Points for Faecal Incontinence

Faecal incontinence is the involuntary loss of control over bowel movements, ranging from mild soiling to complete bowel evacuation.

Diagnosis involves a thorough history, physical examination, stool diary, and investigations such as anorectal manometry and endoanal ultrasound.

First-line treatments include lifestyle changes, pelvic floor exercises, bowel retraining, and medications such as antidiarrhoeals or stool softeners.

Surgical interventions and biofeedback therapy may be needed if conservative treatments fail.

Regular follow-up, bowel diaries, and skin care are important to manage symptoms and prevent complications like skin breakdown or social isolation.

40. Falls

1. Detailed Definition of Falls

Falls are defined as unintentional descents to the ground or lower level, typically without loss of consciousness. Falls are a major health concern in the elderly population, particularly those over the age of 65, due to their association with significant morbidity, mortality, and loss of independence. The causes of falls are often multifactorial, involving a combination of intrinsic factors (such as medical conditions, medications, and sensory impairments) and extrinsic factors (such as environmental hazards). Falls can lead to serious consequences like fractures, head injuries, and a fear of falling again, which can result in reduced mobility and increased frailty.

2. Common Presenting Complaints and Symptoms

Elderly patients presenting with falls may report:

a) Loss of Balance:

Sudden loss of postural control, often described as feeling unstable or wobbly.

b) Dizziness or Vertigo:

Sensation of spinning or lightheadedness before the fall.

c) Syncope or Near-Syncope:

A brief loss of consciousness or a feeling of fainting preceding the fall, often due to orthostatic hypotension, arrhythmias, or vasovagal episodes.

d) Leg Weakness:

Difficulty standing or walking, often related to muscle weakness or neurological conditions such as stroke or Parkinson's disease.

e) Vision Problems:

Difficulty seeing obstacles or changes in floor levels due to cataracts, macular degeneration, or other visual impairments.

f) Injuries from the Fall:

Bruises, cuts, fractures (especially of the hip, wrist, or spine), or head injuries as a result of the fall.

g) Fear of Falling Again:

Anxiety and avoidance of movement due to a previous fall, leading to reduced mobility and increased risk of further falls.

3. First-Line Investigations

To identify the underlying causes of falls in elderly patients, a thorough assessment is required:

a) Comprehensive Falls History:

What it examines: A detailed history of the fall, including when, where, and how it occurred, whether there were any warning symptoms (e.g., dizziness, syncope), and whether the patient was able to get up afterward.

Purpose: Helps identify intrinsic factors (e.g., medical conditions) or extrinsic factors (e.g., environmental hazards) contributing to the fall.

b) Medication Review:

What it examines: A review of all prescribed, over-the-counter, and herbal medications.

Purpose: Identifies medications associated with falls, such as sedatives, antihypertensives, diuretics, or medications with anticholinergic effects.

c) Physical Examination:

What it examines: A complete physical exam focusing on balance, gait, muscle strength, joint function, and neurological examination (to assess sensory deficits, reflexes, and coordination).

Purpose: Identifies underlying conditions such as muscle weakness, arthritis, or neurological disorders that contribute to falls.

d) Orthostatic Blood Pressure Measurement:

What it measures: Blood pressure is measured lying down, then again after standing.

Purpose: Detects orthostatic hypotension (a significant drop in blood pressure upon standing), which is a common cause of dizziness and falls in the elderly.

e) **ECG and Cardiac Monitoring:**

What it examines: Assesses heart rhythm and electrical activity.

Purpose: Identifies arrhythmias, bradycardia, or heart block that may lead to syncope or falls.

f) **Vision and Hearing Tests:**

What it examines: Assesses for visual or auditory impairments.

Purpose: Detects sensory deficits that can increase the risk of falls, such as cataracts or hearing loss.

g) **Blood Tests:**

What they measure: Full blood count (FBC), urea and electrolytes (U&Es), blood glucose, and vitamin D levels.

Purpose: Identifies contributing factors such as anaemia, dehydration, electrolyte imbalances, or vitamin D deficiency that can affect balance and strength.

h) **Imaging (if indicated):**

What it examines: X-rays or CT scans to assess for fractures or head injuries if the patient fell and sustained trauma.

Purpose: Confirms the presence of injuries such as hip fractures or intracranial bleeds, which are common in fall-related trauma.

4. Explanation of Investigations

a) **Orthostatic Blood Pressure Measurement:**

This test is used to diagnose orthostatic hypotension, a common cause of dizziness and falls in the elderly. A significant drop in blood pressure upon standing can lead to lightheadedness or fainting, increasing the risk of falling.

b) **ECG and Cardiac Monitoring:**

These investigations help detect arrhythmias or other heart-related conditions that can cause syncope or dizziness. In some cases, continuous Holter monitoring may be needed to detect intermittent arrhythmias.

c) **Vision and Hearing Tests:**

Sensory impairments can reduce a person's ability to navigate their environment safely. Correcting visual or hearing deficits can reduce the risk of falls.

5. Diagnostic Criteria for Falls

Falls are typically diagnosed based on clinical history and physical examination, with further investigations helping to identify the underlying causes. Diagnostic criteria for underlying causes include:

Orthostatic Hypotension: A drop in systolic blood pressure ≥ 20 mmHg or diastolic blood pressure ≥ 10 mmHg upon standing.

Arrhythmias: Diagnosed through ECG or continuous cardiac monitoring.

Sensory Impairments: Diagnosed through vision or hearing tests, showing significant sensory deficits contributing to falls.

NICE guidelines recommend a multifactorial assessment of falls, focusing on identifying modifiable risk factors such as medication side effects, orthostatic hypotension, sensory impairments, and muscle weakness.

6. First-Line Therapy According to Guidelines

Management of falls in the elderly is multifaceted and focuses on reducing risk factors, preventing future falls, and addressing underlying causes:

a) Lifestyle Modifications:

Home Safety Modifications:

Action: Remove trip hazards (e.g., loose rugs, clutter), install grab rails, improve lighting, and ensure the home environment is fall-proof.

Outcome: Reduces environmental risks that contribute to falls.

Exercise and Strength Training:

Action: Encourage regular physical activity, particularly strength training, balance exercises (e.g., Tai Chi), and physiotherapy.

Outcome: Improves muscle strength, coordination, and balance, reducing the risk of falls.

b) Medication Review and Adjustment:

Action: Discontinue or adjust medications that increase the risk of falls (e.g., sedatives, antihypertensives, anticholinergics).

Outcome: Reduces side effects like dizziness or orthostatic hypotension that contribute to falls.

c) Management of Orthostatic Hypotension:

Increase Fluid and Salt Intake:

Action: Increase hydration and dietary salt intake (if appropriate) to maintain blood pressure upon standing.

Outcome: Prevents drops in blood pressure that can cause fainting or dizziness.

Compression Stockings:

Action: Improve venous return by using compression stockings.

Outcome: Helps prevent blood from pooling in the legs, reducing the risk of orthostatic hypotension.

d) **Vision and Hearing Correction:**

Action: Ensure that vision is corrected with glasses or cataract surgery, and hearing aids are used if needed.

Outcome: Improves sensory function, reducing the risk of tripping or misjudging obstacles.

e) **Vitamin D Supplementation:**

Action: Prescribe vitamin D supplements, particularly in those with low levels, to improve bone and muscle health.

Outcome: Reduces the risk of falls and fractures by improving strength and bone density.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Sedatives and Antihypertensives: Should be used cautiously in elderly patients as they can contribute to falls by causing dizziness, drowsiness, or orthostatic hypotension.

b) **Second-Line Therapy:**

Gait and Balance Training:

Indication: For patients with ongoing balance problems despite first-line interventions.

Mechanism: Physiotherapists or occupational therapists provide tailored exercises to improve balance and walking stability.

Pacemaker or Implantable Cardioverter Defibrillator (ICD):

Indication: For patients with falls related to heart arrhythmias, a pacemaker may be required to regulate heart rhythm.

Multifactorial Fall Prevention Programs:

Indication: Comprehensive programs that include exercise, home safety checks, and medication review for high-risk patients.

8. Routine Monitoring and Follow-Up

a) **Regular Fall Risk Assessments:**

Patients should be reassessed periodically to evaluate their risk of falls and ensure interventions are effective.

b) **Medication Review:**

Medications should be regularly reviewed, particularly if new falls occur, to identify any drugs contributing to dizziness, weakness, or syncope.

c) **Bone Health Monitoring:**

In patients at risk of fractures, regular bone density assessments and continued vitamin D and calcium supplementation are important to prevent osteoporosis.

9. Complications of Falls

a) **Fractures:**

Hip fractures are the most serious complication of falls in the elderly, often leading to long hospital stays, surgery, and loss of independence.

b) **Head Injuries:**

Falls can result in head trauma, including concussions or subdural hematomas, particularly in patients on anticoagulation therapy.

c) **Fear of Falling:**

A previous fall can lead to a fear of falling again, resulting in reduced mobility, physical deconditioning, and a higher risk of further falls.

d) **Hospitalisation and Loss of Independence:**

Recurrent falls often lead to hospital admissions, long-term care placements, and a decline in overall health and functional ability.

Summary of Key Points for Falls in the Elderly

Falls are common in elderly patients and often have multiple contributing factors, including muscle weakness, sensory impairments, orthostatic hypotension, and medication side effects.

A thorough assessment, including a falls history, physical examination, medication review, and orthostatic blood pressure measurement, is essential for identifying the underlying cause.

First-line treatment includes lifestyle modifications (home safety, exercise), medication adjustments, and management of orthostatic hypotension or sensory deficits.

Regular monitoring, fall risk assessments, and continued support are crucial to reducing the risk of recurrent falls and preventing complications like fractures or hospitalisation.

41. Fluid and Electrolyte Imbalance

1. Detailed Definition of Fluid and Electrolyte Imbalance

Fluid and electrolyte imbalances occur when the body's levels of fluids and essential minerals such as sodium, potassium, calcium, and magnesium are either too high or too low, disrupting normal bodily functions. These imbalances are common in elderly patients due to age-related changes in kidney function, decreased thirst sensation, comorbidities, and the use of certain medications (e.g., diuretics, antihypertensives). Fluid imbalances can manifest as dehydration or fluid overload, while electrolyte disturbances may involve conditions such as hyponatraemia (low sodium), hyperkalaemia (high potassium), or hypocalcaemia (low calcium).

2. Common Presenting Complaints and Symptoms

Patients with fluid and electrolyte imbalances may present with:

a) Dehydration:

Dry mucous membranes and skin, decreased skin turgor.

Thirst, confusion, dizziness, and lightheadedness.

Reduced urine output, concentrated urine.

Hypotension and tachycardia due to reduced circulating blood volume.

b) Fluid Overload:

Swelling (oedema) in the lower extremities, around the eyes, or in the abdomen.

Shortness of breath due to pulmonary oedema.

Weight gain, particularly if rapid or unexplained.

Elevated blood pressure, jugular venous distension (JVD).

c) Hyponatraemia (Low Sodium):

Nausea, vomiting, headache.

Confusion, lethargy, and agitation, which may progress to seizures in severe cases.

Muscle cramps or weakness.

d) Hypernatraemia (High Sodium):

Thirst, restlessness, and irritability.

Dry mouth and mucous membranes, reduced skin elasticity.

Neurological symptoms, including confusion, seizures, or coma.

e) Hyperkalaemia (High Potassium):

Generalised weakness or paralysis.

Abnormal heart rhythms, palpitations, or chest discomfort.

In severe cases, it can lead to cardiac arrest.

f) Hypokalaemia (Low Potassium):

Muscle weakness, cramps, or paralysis.

Fatigue and lethargy.

Constipation or ileus due to impaired gastrointestinal motility.

Cardiac arrhythmias or palpitations.

g) Hypocalcaemia (Low Calcium):

Numbness or tingling in the extremities or around the mouth.

Muscle cramps, spasms (tetany), or seizures.

Positive Chvostek's sign (facial twitching in response to tapping on the facial nerve).

Prolonged QT interval on ECG, increasing the risk of arrhythmias.

h) Hypercalcaemia (High Calcium):

Nausea, vomiting, abdominal pain, constipation.

Fatigue, lethargy, and confusion.

Increased thirst and frequent urination.

Shortened QT interval on ECG, which can lead to arrhythmias.

3. First-Line Investigations

Assessment of fluid and electrolyte imbalances involves both clinical evaluation and laboratory investigations:

a) History and Physical Examination:

What it examines: Fluid intake/output, recent illnesses, use of medications (e.g., diuretics, laxatives), and symptoms like dizziness, oedema, or confusion.

Purpose: Helps determine whether the patient is at risk for dehydration, fluid overload, or specific electrolyte imbalances.

b) Serum Electrolytes (Urea & Electrolytes - U&Es):

What it measures: Sodium, potassium, urea, and creatinine levels.

Purpose: Detects abnormalities in electrolyte levels (e.g., hyponatraemia, hyperkalaemia) and assesses kidney function, which plays a critical role in fluid balance.

c) Serum Osmolality:

What it measures: The concentration of solutes in the blood, indicating fluid status.

Purpose: Useful in diagnosing causes of hyponatraemia or hypernatraemia (e.g., dehydration vs fluid overload).

d) Urine Electrolytes and Osmolality:

What it measures: Urinary sodium and potassium levels, as well as urine osmolality.

Purpose: Helps identify the cause of electrolyte imbalances (e.g., renal vs non-renal causes of sodium loss).

e) Arterial Blood Gas (ABG):

What it measures: Blood pH, bicarbonate, and partial pressure of carbon dioxide ($p\text{CO}_2$).

Purpose: Assesses for acid-base imbalances (e.g., metabolic acidosis or alkalosis), which often accompany electrolyte imbalances.

f) **ECG:**

What it examines: Heart rhythm and electrical activity.

Purpose: Detects arrhythmias or changes in heart conduction patterns that may be caused by electrolyte disturbances, particularly potassium or calcium abnormalities (e.g., peaked T waves in hyperkalaemia).

g) **Fluid Balance Chart:**

What it examines: A record of all fluid intake and output over 24 hours.

Purpose: Helps assess whether the patient is in fluid overload or dehydration.

4. Explanation of Investigations

a) **Serum Electrolytes (U&Es):** This test provides essential information on the levels of electrolytes like sodium and potassium, which are critical for maintaining fluid balance and neuromuscular function. It also assesses renal function through urea and creatinine levels, helping to determine whether kidney disease may be contributing to the imbalance.

b) **Serum Osmolality:** Helps assess whether electrolyte disturbances (e.g., hyponatraemia) are due to water retention, dehydration, or inappropriate ADH secretion (SIADH). Low osmolality indicates excess water, while high osmolality suggests dehydration.

c) **ECG:** Electrolyte imbalances, particularly potassium and calcium disturbances, can cause characteristic changes on an ECG. Hyperkalaemia, for example, may present with peaked T waves, while hypocalcaemia can prolong the QT interval.

5. Diagnostic Criteria for Fluid and Electrolyte Imbalance

Fluid and electrolyte imbalances are diagnosed based on clinical presentation and laboratory findings:

Dehydration: Identified through clinical signs (e.g., dry mucous membranes, hypotension) and laboratory findings of elevated serum sodium, urea, and osmolality.

Hyponatraemia: Diagnosed when serum sodium is <135 mmol/L, with further categorisation based on volume status (hypovolaemic, euvolaemic, or hypervolaemic).

Hyperkalaemia: Diagnosed when serum potassium is >5.0 mmol/L, with accompanying ECG changes in severe cases.

Hypocalcaemia: Serum calcium <2.2 mmol/L, often associated with neuromuscular symptoms or ECG changes.

NICE guidelines recommend prompt identification of fluid and electrolyte imbalances to prevent complications and guide appropriate treatment.

6. First-Line Therapy According to Guidelines

Management of fluid and electrolyte imbalances involves correcting the underlying disturbance, addressing symptoms, and preventing complications:

a) Dehydration:

Oral or Intravenous (IV) Rehydration:

Action: Administer oral fluids or IV isotonic fluids (e.g., 0.9% saline) to correct dehydration.

Outcome: Restores normal fluid balance and improves symptoms such as hypotension and confusion.

b) Hyponatraemia:

Fluid Restriction (for euvolaemic hyponatraemia):

Action: Limit fluid intake in patients with conditions like SIADH.

Outcome: Prevents further dilution of sodium and improves serum sodium levels.

IV Saline (for hypovolaemic hyponatraemia):

Action: Administer IV 0.9% saline to correct both volume depletion and sodium levels.

Outcome: Restores normal volume status and sodium concentration.

c) Hyperkalaemia:

Calcium Gluconate (if ECG changes present):

Action: Administer calcium gluconate IV to stabilise the cardiac membrane.

Outcome: Prevents life-threatening arrhythmias in the setting of severe hyperkalaemia.

Insulin and Glucose:

Action: Administer IV insulin and glucose to drive potassium back into cells.

Outcome: Rapidly reduces serum potassium levels.

Loop Diuretics or Dialysis (in severe cases):

Action: Remove excess potassium via diuresis or dialysis.

Outcome: Reduces serum potassium levels, particularly in patients with renal failure.

d) Hypocalcaemia:

IV Calcium Replacement:

Action: Administer IV calcium gluconate in symptomatic patients (e.g., with tetany or seizures).

Outcome: Normalises calcium levels and reduces neuromuscular irritability.

e) Fluid Overload:

Diuretics (e.g., Furosemide):

Action: Administer loop diuretics to promote fluid excretion in patients with heart failure or kidney disease.

Outcome: Reduces oedema, pulmonary congestion, and blood pressure.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Rapid Sodium Correction: Rapid correction of hyponatraemia (e.g., >10 mmol/L in 24 hours) can lead to osmotic demyelination syndrome, which causes severe neurological damage.

b) Second-Line Therapy:

Dialysis:

Indication: For patients with severe fluid overload, hyperkalaemia, or metabolic acidosis that does not respond to medical therapy.

Mechanism: Removes excess fluids and electrolytes through an artificial filtration system.

Vasopressin Antagonists (e.g., Tolvaptan):

Indication: For managing SIADH-related hyponatraemia that does not respond to fluid restriction.

Mechanism: Inhibits the action of ADH, promoting water excretion without losing sodium.

8. Routine Monitoring and Follow-Up

a) Electrolyte Monitoring:

Frequent monitoring of serum electrolytes (e.g., sodium, potassium, calcium) is essential to ensure that levels are being corrected and to prevent further imbalances.

b) Fluid Balance:

Regular monitoring of fluid intake and output, particularly in patients at risk of dehydration or fluid overload.

c) ECG Monitoring:

In patients with severe electrolyte disturbances (e.g., hyperkalaemia or hypocalcaemia), ECG monitoring is important to detect any arrhythmias or cardiac abnormalities.

9. Complications of Fluid and Electrolyte Imbalance

a) Cardiac Arrhythmias:

Electrolyte disturbances, especially hyperkalaemia and hypocalcaemia, can lead to dangerous arrhythmias and, if untreated, cardiac arrest.

b) Osmotic Demyelination Syndrome:

Overly rapid correction of hyponatraemia can lead to this severe neurological condition, resulting in irreversible damage.

c) **Renal Failure:**

Severe dehydration, hyperkalaemia, or acidosis can lead to acute kidney injury, particularly in patients with pre-existing renal impairment.

d) **Seizures:**

Severe hyponatraemia or hypocalcaemia can cause seizures due to abnormal neuronal excitability.

Summary of Key Points for Fluid and Electrolyte Imbalance

Fluid and electrolyte imbalances are common in elderly patients and can present as dehydration, fluid overload, or specific electrolyte disturbances (e.g., hyponatraemia, hyperkalaemia).

Diagnosis relies on clinical assessment and laboratory tests (e.g., serum electrolytes, osmolality, ABG).

First-line treatment involves fluid management (oral or IV rehydration), electrolyte correction (e.g., IV calcium for hypocalcaemia, insulin for hyperkalaemia), and management of underlying causes.

Regular monitoring of electrolytes, fluid balance, and ECG is essential to prevent complications such as arrhythmias or renal failure.

42. Frailty

1. Detailed Definition of Frailty

Frailty is a clinical syndrome characterised by a decline in an individual's physiological reserves across multiple organ systems, leading to increased vulnerability to stressors such as illness, surgery, or changes in medication. It is commonly seen in elderly patients and is associated with higher risks of falls, hospitalisations, disability, and mortality. Frailty can develop due to a combination of factors, including chronic diseases, malnutrition, cognitive decline, and decreased physical activity. It is a dynamic condition, meaning it can fluctuate and potentially be reversed or slowed with appropriate interventions.

Frailty is often identified using assessments such as the **Frailty Phenotype (Fried Criteria)** or the **Clinical Frailty Scale (CFS)**.

2. Common Presenting Complaints and Symptoms

Patients with frailty may present with:

a) **Fatigue:**

Unexplained tiredness and reduced energy levels, making daily activities more difficult to perform.

b) **Unintentional Weight Loss:**

Significant, unintentional weight loss (more than 5% of body weight over 6–12 months), often due to reduced appetite or malnutrition.

c) Weakness:

Generalised muscle weakness, particularly in the arms and legs, leading to difficulty with mobility and activities of daily living (ADLs).

d) Slow Walking Speed:

Slower than normal walking pace, often requiring a walking aid or frequent stops due to fatigue or balance problems.

e) Reduced Physical Activity:

Decreased engagement in regular physical or social activities due to fatigue, weakness, or fear of falling.

f) Increased Susceptibility to Falls:

Recurrent falls or near-falls due to impaired balance, muscle weakness, or postural instability.

g) Cognitive Decline:

Mild cognitive impairment, memory problems, or difficulty with concentration, which may accompany physical frailty.

3. First-Line Investigations

Assessment of frailty in elderly patients includes both clinical evaluation and functional assessments:

a) Comprehensive Geriatric Assessment (CGA):

What it examines: A multidisciplinary evaluation of medical, functional, cognitive, psychological, and social factors.

Purpose: Identifies the degree of frailty, the presence of comorbid conditions, and any functional impairments that need addressing.

b) Frailty Screening Tools:

Clinical Frailty Scale (CFS):

What it measures: A 9-point scale that assesses the severity of frailty, ranging from 1 (very fit) to 9 (terminally ill).

Purpose: Provides a quick visual assessment of frailty based on the patient's mobility, daily activities, and independence.

Frailty Phenotype (Fried Criteria):

What it measures: Assesses five key features: unintentional weight loss, exhaustion, weakness, slow walking speed, and low physical activity.

Purpose: Identifies patients as frail if three or more criteria are met, pre-frail if one or two criteria are met.

c) Timed Up and Go (TUG) Test:

What it measures: Time taken for the patient to stand from a seated position, walk 3 metres, turn around, and return to the chair.

Purpose: Assesses mobility, balance, and risk of falls. A time of >12 seconds suggests increased fall risk and frailty.

d) Grip Strength Measurement:

What it measures: Muscle strength using a hand dynamometer.

Purpose: Reduced grip strength is a hallmark of physical frailty and correlates with overall muscle weakness.

e) Blood Tests (e.g., full blood count, vitamin D levels, renal function):

What they measure: Identifies anaemia, malnutrition, vitamin deficiencies, or other underlying conditions that may contribute to frailty.

Purpose: Helps assess and treat any correctable causes of frailty, such as malnutrition or underlying disease.

f) Nutritional Assessment (e.g., Malnutrition Universal Screening Tool - MUST):

What it examines: Assesses nutritional status, focusing on weight loss, BMI, and dietary intake.

Purpose: Identifies patients at risk of malnutrition, which is closely linked to frailty.

4. Explanation of Investigations

a) Clinical Frailty Scale (CFS):

The CFS provides a simple and quick tool to assess a patient's degree of frailty, considering their physical activity, independence, and overall health. It is commonly used in clinical settings for care planning and decision-making.

b) Grip Strength Measurement:

A hand dynamometer measures grip strength, which is an indicator of overall muscle function. Grip strength below a certain threshold (depending on sex and age) indicates muscle weakness and is predictive of frailty, disability, and mortality.

c) Timed Up and Go (TUG) Test:

The TUG test is an objective measure of balance, mobility, and risk of falls. It is especially useful in assessing frailty and predicting falls in elderly patients. A longer time to complete the test suggests greater frailty and an increased fall risk.

5. Diagnostic Criteria for Frailty

Frailty is diagnosed based on clinical assessment and functional testing. The most commonly used diagnostic criteria are:

Fried's Frailty Phenotype: A patient is considered frail if they meet 3 or more of the following criteria:

Unintentional weight loss ($\geq 5\%$ body weight in the last year).

Self-reported exhaustion.

Weak grip strength.

Slow walking speed.

Low physical activity levels.

Clinical Frailty Scale (CFS): A score of ≥ 5 indicates frailty. Scores range from 1 (very fit) to 9 (terminally ill), with 5 indicating mild frailty, 6 moderate frailty, and 7 severe frailty.

According to **NICE guidelines**, identifying frailty early in elderly patients is essential for implementing targeted interventions to improve outcomes and reduce the risk of complications such as falls and hospitalisation.

6. First-Line Therapy According to Guidelines

Management of frailty focuses on addressing its underlying causes and preventing its progression. Key interventions include:

a) Exercise and Physical Therapy:

Strength and Balance Training:

Action: Engage in regular resistance training and balance exercises (e.g., Tai Chi, physiotherapy).

Outcome: Improves muscle strength, mobility, and reduces the risk of falls. Exercise also helps maintain independence.

Walking Aids and Assistive Devices:

Action: Provide mobility aids such as canes or walkers.

Outcome: Increases stability, reduces fall risk, and enhances confidence in movement.

b) Nutritional Support:

Dietary Counselling and Supplementation:

Action: Encourage a balanced diet rich in protein, calories, and essential vitamins (e.g., vitamin D, calcium) to prevent muscle loss and support bone health.

Outcome: Improves nutritional status and reduces the risk of frailty-related complications, such as muscle wasting and fractures.

Oral Nutritional Supplements:

Action: Prescribe supplements for patients with malnutrition or at risk of weight loss.

Outcome: Supports weight gain, improves muscle mass, and enhances overall strength.

c) Medication Review:

Action: Regularly review medications to identify and discontinue those that may contribute to frailty, such as sedatives, anticholinergics, or polypharmacy.

Outcome: Reduces the risk of falls, confusion, and adverse effects from unnecessary medications.

d) Falls Prevention:

Action: Implement fall prevention strategies, such as home safety assessments, exercise programs, and use of mobility aids.

Outcome: Reduces the risk of falls, fractures, and hospitalisations.

e) Treatment of Underlying Conditions:

Action: Address comorbidities such as diabetes, hypertension, depression, or osteoarthritis, which may exacerbate frailty.

Outcome: Improves overall health and reduces the impact of chronic diseases on frailty.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Sedentary Lifestyle: Physical inactivity should be discouraged as it worsens muscle weakness and accelerates the progression of frailty.

b) Second-Line Therapy:

Occupational Therapy:

Indication: For patients struggling with daily tasks due to frailty.

Mechanism: Occupational therapists can provide assistive devices and strategies to improve independence with activities of daily living (ADLs).

Comprehensive Geriatric Assessment (CGA):

Indication: For patients with severe or rapidly progressing frailty.

Mechanism: A multidisciplinary team assesses medical, psychological, and functional status to develop a personalised care plan.

8. Routine Monitoring and Follow-Up

a) Regular Frailty Assessments:

Patients should be reassessed periodically using the CFS, Fried's Phenotype, or other frailty tools to monitor progression or improvement.

b) Nutritional Monitoring:

Monitor weight, BMI, and dietary intake regularly to ensure nutritional needs are met and to adjust supplementation or meal plans as needed.

c) **Exercise Adherence:**

Ensure that patients are adhering to their prescribed exercise or physical therapy program. Follow-up with physiotherapists can help with motivation and progression.

9. Complications of Frailty

a) **Increased Risk of Falls and Fractures:**

Frailty is associated with poor balance, muscle weakness, and instability, leading to frequent falls and fractures, particularly of the hip and wrist.

b) **Functional Decline and Disability:**

As frailty progresses, patients may lose the ability to perform basic activities of daily living, leading to loss of independence and increased reliance on caregivers.

c) **Hospitalisation and Prolonged Recovery:**

Frailty increases the risk of hospitalisation, often due to falls, infections, or worsening of chronic diseases. Recovery times are prolonged, and there is a higher risk of complications during hospital stays.

d) **Increased Mortality:**

Frailty is a significant predictor of mortality in elderly patients, particularly when associated with other chronic diseases or after acute illnesses such as infections or injuries.

Summary of Key Points for Frailty

Frailty is a syndrome characterised by decreased physiological reserves, making elderly patients more vulnerable to stressors like illness and injury.

Diagnosis is based on clinical assessments such as the **Fried Phenotype** or **Clinical Frailty Scale (CFS)**, which evaluate factors like muscle strength, weight loss, and physical activity.

First-line treatments include exercise, nutritional support, medication review, and fall prevention strategies.

Regular monitoring is essential to track progression, and multidisciplinary care can help address underlying causes and prevent complications like falls, hospitalisation, and loss of independence.

43. Immobility

1. Detailed Definition of Immobility

Immobility refers to a significant reduction in the ability to move or engage in normal physical activities, often seen in elderly patients due to various physical, psychological, and social factors. It can be partial (difficulty moving certain parts of the body) or complete (inability to move independently). Immobility in the elderly is often multifactorial, caused by conditions such as muscle weakness, joint pain (e.g., osteoarthritis), neurological disorders (e.g., stroke or Parkinson's disease), or fear of falling. Prolonged immobility can lead to severe complications,

including muscle wasting, pressure ulcers, deep vein thrombosis (DVT), and reduced quality of life.

2. Common Presenting Complaints and Symptoms

Elderly patients with immobility may present with:

a) Difficulty Walking:

Reduced ability to walk short distances, often requiring assistance or mobility aids (e.g., walking frames, canes).

b) Pain with Movement:

Joint or muscle pain during movement, commonly due to conditions such as osteoarthritis, fractures, or muscle atrophy.

c) Muscle Weakness:

Generalised muscle weakness, especially in the legs, which limits the ability to stand or walk.

d) Fatigue:

Quick exhaustion or shortness of breath during even minimal physical activity, contributing to reduced mobility.

e) Fear of Falling:

Anxiety about falling again after previous falls, leading to avoidance of movement and further immobility.

f) Neurological Deficits:

Symptoms such as limb paralysis, spasticity, or impaired coordination in patients with stroke, Parkinson's disease, or other neurological conditions.

g) Swelling and Stiffness:

Joint swelling and stiffness, especially in the morning, making movement difficult and painful.

3. First-Line Investigations

To identify the underlying causes and complications of immobility, a comprehensive assessment is required, including both clinical evaluation and functional tests:

a) Comprehensive Geriatric Assessment (CGA):

What it examines: A multidisciplinary evaluation of physical, cognitive, psychological, and social factors.

Purpose: Identifies contributing factors to immobility, including medical conditions, medication side effects, and social barriers.

b) Physical Examination:

What it examines: Muscle strength, joint range of motion, gait, and balance.

Purpose: Assesses for musculoskeletal, neurological, or balance impairments contributing to immobility.

c) Timed Up and Go (TUG) Test:

What it measures: Time taken for the patient to rise from a chair, walk 3 metres, turn around, and return to the chair.

Purpose: Evaluates balance, gait, and overall mobility. A longer time suggests increased immobility and fall risk.

d) Grip Strength Test:

What it measures: Measures muscle strength in the hands using a dynamometer.

Purpose: Weak grip strength often correlates with general muscle weakness and reduced mobility.

e) Blood Tests (e.g., Full Blood Count, Vitamin D levels, Inflammatory Markers):

What they measure: Identifies anaemia, vitamin D deficiency, or chronic inflammation, which may contribute to fatigue, weakness, or joint pain.

Purpose: Helps detect underlying conditions such as osteoporosis, inflammatory arthritis, or malnutrition that may worsen immobility.

f) Imaging (e.g., X-ray, MRI, CT scan):

What it examines: Joint and bone structure, particularly in cases of suspected osteoarthritis, fractures, or spinal abnormalities.

Purpose: Helps diagnose conditions like arthritis, fractures, or spinal stenosis that restrict movement.

g) Neurological Assessment:

What it examines: Assesses motor, sensory, and coordination functions, particularly in patients with stroke, Parkinson's disease, or other neurological disorders.

Purpose: Identifies neurological impairments that contribute to immobility.

4. Explanation of Investigations

a) Timed Up and Go (TUG) Test:

This test is a reliable measure of mobility, balance, and fall risk. A time of more than 12 seconds to complete the test is associated with increased immobility and a higher risk of falls.

b) Grip Strength Test:

Weak grip strength is an indicator of overall muscle strength and frailty. It can be used to predict mobility limitations and the risk of disability.

c) **Imaging:**

X-rays, MRIs, or CT scans are used to identify musculoskeletal or neurological causes of immobility, such as osteoarthritis, fractures, or degenerative disc disease.

5. Diagnostic Criteria for Immobility

Immobility is diagnosed based on clinical assessment, functional testing, and identification of underlying conditions. Key diagnostic criteria include:

Inability or Difficulty Moving Independently: Struggling to perform basic movements (e.g., standing, walking) or requiring assistance to do so.

Muscle Weakness or Joint Stiffness: Weakness, stiffness, or pain in muscles or joints that significantly limits mobility.

Underlying Causes: Diagnosed through tests such as imaging (for osteoarthritis, fractures) or blood tests (for anaemia, vitamin D deficiency).

NICE guidelines recommend a comprehensive, multidisciplinary approach to assessing immobility, particularly in elderly patients, with attention to identifying reversible causes and complications such as falls or pressure sores.

6. First-Line Therapy According to Guidelines

Management of immobility focuses on improving movement, preventing complications, and addressing underlying causes. Key interventions include:

a) **Physical Therapy and Exercise:**

Strength and Balance Training:

Action: Prescribe regular physical therapy exercises to improve muscle strength, coordination, and balance.

Outcome: Enhances mobility, reduces the risk of falls, and maintains independence.

Range of Motion Exercises:

Action: Help maintain or improve joint flexibility in patients with joint stiffness or limited mobility.

Outcome: Prevents joint contractures and enhances movement.

b) **Use of Mobility Aids:**

Walking Aids:

Action: Provide canes, walkers, or frames to assist with ambulation.

Outcome: Improves stability and confidence in movement, reducing the risk of falls.

Wheelchairs or Power Chairs:

Action: For patients with severe immobility, assistive devices such as wheelchairs may be necessary for mobility.

Outcome: Allows for greater independence and participation in social activities.

c) Pain Management:

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs):

Indication: For patients with joint pain due to osteoarthritis or inflammatory conditions.

Mechanism: Reduces inflammation and pain, making movement easier.

Analgesics or Topical Pain Relievers:

Indication: For patients with musculoskeletal pain, topical analgesics (e.g., capsaicin) or oral painkillers (e.g., paracetamol) can be used.

d) Nutritional Support:

Vitamin D and Calcium Supplementation:

Action: Supplement vitamin D and calcium in patients with deficiencies or osteoporosis.

Outcome: Improves bone health and muscle function, reducing the risk of fractures and weakness.

High-Protein Diet:

Action: Encourage a diet rich in protein to support muscle maintenance and prevent further weakness.

e) Environmental Modifications:

Home Safety Improvements:

Action: Remove trip hazards, install grab bars, and make other adjustments in the patient's home to support safe mobility.

Outcome: Reduces the risk of falls and enhances independence.

f) Management of Underlying Conditions:

Treatment of Osteoarthritis:

Action: Provide joint injections (e.g., corticosteroids) or refer for joint replacement surgery in severe cases.

Outcome: Reduces joint pain and stiffness, improving mobility.

Neurological Rehabilitation:

Action: For patients with conditions like stroke or Parkinson's disease, tailored rehabilitation programs can help improve motor function.

Outcome: Enhances movement and reduces the impact of neurological deficits on mobility.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Prolonged Bed Rest: Prolonged immobilisation should be avoided as it leads to muscle wasting, joint stiffness, and other complications such as pressure sores or DVT.

b) Second-Line Therapy:

Occupational Therapy:

Indication: For patients with difficulty performing activities of daily living (ADLs) due to immobility.

Mechanism: Occupational therapists provide strategies and equipment (e.g., dressing aids) to improve independence.

Surgical Interventions:

Indication: In cases of severe joint damage (e.g., osteoarthritis) or fractures, surgery may be required (e.g., joint replacement, fracture fixation).

8. Routine Monitoring and Follow-Up

a) Mobility Assessments:

Patients should be regularly reassessed for improvements or deterioration in mobility, and exercise programs should be adjusted accordingly.

b) Fall Risk Assessments:

Monitor for falls and adjust the environment, medication, or physiotherapy as needed to reduce fall risk.

c) Muscle Strength Monitoring:

Track muscle strength, particularly in the lower extremities, to assess the effectiveness of physiotherapy and nutritional interventions.

9. Complications of Immobility

a) Muscle Atrophy:

Prolonged immobility leads to muscle wasting, particularly in the legs, which worsens mobility and increases frailty.

b) Pressure Ulcers:

Patients who are bed-bound or chair-bound for prolonged periods are at high risk of developing pressure sores, particularly over bony prominences like the sacrum or heels.

c) Deep Vein Thrombosis (DVT):

Prolonged immobility increases the risk of blood clot formation in the deep veins, particularly in the legs, which can lead to pulmonary embolism if left untreated.

d) **Contractures:**

In patients with joint stiffness or muscle weakness, prolonged immobility can lead to permanent contractures, further limiting movement.

e) **Social Isolation and Depression:**

Reduced mobility often leads to social isolation, dependence on others, and depression due to the loss of independence and reduced participation in activities.

Summary of Key Points for Immobility in the Elderly

Immobility is a common issue in elderly patients and is often multifactorial, involving musculoskeletal, neurological, and psychological factors.

Diagnosis is based on clinical assessment and functional tests like the **Timed Up and Go (TUG) Test** and **Grip Strength Measurement**, along with investigations to identify underlying causes (e.g., osteoarthritis, stroke).

First-line management includes physical therapy, mobility aids, pain management, and treatment of underlying conditions.

Regular monitoring and multidisciplinary interventions are essential to prevent complications such as muscle atrophy, pressure ulcers, and deep vein thrombosis.

44. Infection

1. Detailed Definition of Infection

Infections in elderly patients are common and can be caused by a wide range of pathogens, including bacteria, viruses, and fungi. The immune system weakens with age, making elderly individuals more susceptible to infections, which may also present atypically. Infections in older adults are often more severe, leading to complications such as sepsis, increased hospitalisation, and higher mortality rates. The most common infections in this population include urinary tract infections (UTIs), respiratory infections (e.g., pneumonia), skin infections, and gastrointestinal infections.

2. Common Presenting Complaints and Symptoms

Infections in elderly patients may present with a combination of specific and non-specific symptoms. Atypical presentations, such as confusion or a decline in functional status, are common.

a) **General Symptoms:**

Fever or low-grade fever (but fever may be absent or blunted).

Fatigue, malaise, or weakness.

Loss of appetite and unintentional weight loss.

Acute confusion (delirium) or mental status changes.

Falls, functional decline, or inability to perform activities of daily living (ADLs).

b) Specific Symptoms Based on Infection Site:

Urinary Tract Infection (UTI):

Dysuria (pain or burning with urination).

Increased frequency or urgency of urination.

Lower abdominal or suprapubic pain.

Incontinence or new onset confusion (delirium).

Respiratory Infections (e.g., Pneumonia, Bronchitis):

Cough, productive or non-productive.

Shortness of breath, wheezing, or chest pain.

Increased sputum production (in pneumonia).

Hypoxia or cyanosis in severe cases.

Skin and Soft Tissue Infections:

Localised redness, warmth, swelling, or pain (e.g., cellulitis).

Ulcers, abscesses, or wounds with drainage.

Gastrointestinal Infections:

Diarrhoea or vomiting.

Abdominal pain or cramping.

Dehydration or signs of electrolyte imbalance.

Sepsis:

Fever or hypothermia.

Tachycardia, tachypnoea.

Hypotension or signs of organ dysfunction (e.g., altered consciousness, reduced urine output).

3. First-Line Investigations

Prompt investigation is crucial to diagnose the infection, identify the causative organism, and prevent complications such as sepsis. Key investigations include:

a) Full Blood Count (FBC):

What it measures: White blood cell (WBC) count, haemoglobin, platelets.

Purpose: Detects signs of infection (e.g., elevated WBC count), anaemia, or thrombocytopenia, which may accompany infection or sepsis.

b) C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR):

What they measure: Markers of inflammation.

Purpose: Elevated CRP and ESR levels indicate an acute inflammatory response, supporting the diagnosis of infection.

c) **Blood Cultures:**

What it examines: Blood samples for bacterial growth.

Purpose: Identifies bacteraemia in cases of suspected sepsis or systemic infection, guiding antibiotic treatment.

d) **Urine Dipstick and Culture** (for suspected UTI):

What it measures: Detects nitrites, leukocytes, and bacteria in the urine.

Purpose: Confirms the presence of a urinary tract infection and identifies the causative organism through urine culture.

e) **Chest X-ray** (for suspected respiratory infection):

What it examines: Lung fields and airways.

Purpose: Detects pneumonia, bronchitis, or other lung pathology.

f) **Sputum Culture** (for suspected pneumonia or bronchitis):

What it examines: Sputum samples for bacterial growth.

Purpose: Identifies the causative organism in respiratory infections, guiding targeted antibiotic therapy.

g) **Wound Swab and Culture** (for skin and soft tissue infections):

What it examines: Samples of wound exudate or discharge.

Purpose: Detects bacteria and helps guide appropriate antibiotic treatment for cellulitis, abscesses, or ulcers.

h) **Stool Culture** (for suspected gastrointestinal infection):

What it examines: Stool samples for bacteria, viruses, or parasites.

Purpose: Identifies the causative organism in cases of diarrhoea or gastroenteritis.

i) **Blood Gas Analysis (Arterial Blood Gas - ABG)** (for severe infection or sepsis):

What it measures: Blood pH, oxygen, and carbon dioxide levels.

Purpose: Assesses for respiratory or metabolic acidosis, hypoxia, or hypercapnia, especially in critically ill patients.

4. Explanation of Investigations

a) **Blood Cultures:**

Blood cultures are essential when there is suspicion of bacteraemia or sepsis. Samples are

drawn from two different sites and cultured to detect the presence of pathogens in the bloodstream, which can guide the selection of appropriate antibiotics.

b) Urine Dipstick and Culture:

A urine dipstick is a rapid screening tool that detects signs of infection, such as the presence of nitrites (from bacterial metabolism) and leukocytes (white blood cells). A urine culture identifies the specific bacteria causing the infection and determines antibiotic sensitivity.

c) Chest X-ray:

A chest X-ray is useful in diagnosing pneumonia, which may present with consolidation, infiltrates, or pleural effusion. It helps differentiate between bacterial, viral, or aspiration pneumonia.

5. Diagnostic Criteria for Infection

The diagnosis of infection in the elderly is based on clinical symptoms, physical examination, and investigations. Specific diagnostic criteria include:

Urinary Tract Infection (UTI): Diagnosed with symptoms of dysuria, frequency, or urgency, and confirmed with a positive urine culture showing significant bacterial growth.

Pneumonia: Diagnosed through symptoms (cough, fever, shortness of breath) and radiological evidence of lung consolidation or infiltrates on a chest X-ray.

Sepsis: Defined by the presence of infection with organ dysfunction (using the SOFA score), which may include hypotension, altered mental status, or hypoxia. Sepsis is a medical emergency requiring urgent intervention.

NICE guidelines recommend a prompt and thorough investigation of infections in the elderly, especially in those with atypical presentations such as confusion or functional decline.

6. First-Line Therapy According to Guidelines

The management of infections in elderly patients depends on the type and severity of the infection, with prompt treatment essential to prevent complications such as sepsis or organ failure:

a) Antibiotic Therapy:

Empiric Antibiotics (based on the suspected source):

Action: Initiate broad-spectrum antibiotics (e.g., co-amoxiclav, piperacillin-tazobactam) while awaiting culture results.

Outcome: Provides immediate treatment while specific pathogens are identified.

Targeted Antibiotics (based on culture results):

Action: Adjust antibiotics based on culture sensitivity results to narrow down the treatment.

Outcome: Targets the causative organism while reducing the risk of antibiotic resistance.

b) Supportive Care:

Fluid Resuscitation:

Action: Administer intravenous fluids (e.g., normal saline) to maintain blood pressure and organ perfusion, particularly in cases of sepsis or dehydration.

Outcome: Prevents hypovolaemia and improves renal function and overall circulatory status.

Oxygen Therapy:

Action: Administer supplemental oxygen to patients with hypoxia or respiratory distress.

Outcome: Improves oxygenation and reduces the risk of respiratory failure, particularly in pneumonia or sepsis.

c) Specific Therapies Based on Infection Site:**Urinary Tract Infection (UTI):**

Action: Treat with antibiotics such as nitrofurantoin, trimethoprim, or cefalexin, depending on culture sensitivity.

Outcome: Clears infection and prevents complications such as pyelonephritis or sepsis.

Pneumonia:

Action: Administer antibiotics (e.g., amoxicillin, doxycycline, or clarithromycin) depending on severity and culture results.

Outcome: Resolves lung infection and prevents respiratory failure.

Skin Infections (e.g., Cellulitis):

Action: Treat with oral or intravenous antibiotics (e.g., flucloxacillin) and local wound care.

Outcome: Reduces infection, swelling, and prevents abscess formation or systemic infection.

d) Prevention of Sepsis:**Early Sepsis Treatment:**

Action: Follow the "Sepsis Six" protocol: administer antibiotics, fluids, oxygen, take blood cultures, measure lactate, and monitor urine output.

Outcome: Improves survival in patients with sepsis by initiating treatment within the first hour of diagnosis.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:**

Antibiotic Overuse: Overuse of broad-spectrum antibiotics can contribute to antibiotic resistance. Avoid unnecessary antibiotic use in viral infections or asymptomatic bacteriuria.

b) Second-Line Therapy:**Hospitalisation:**

Indication: For patients with severe infections (e.g., pneumonia, sepsis) who require intravenous antibiotics, fluids, and oxygen therapy.

Surgical Drainage:

Indication: For abscesses or infected wounds that do not respond to antibiotics alone, surgical drainage may be required to control the infection.

8. Routine Monitoring and Follow-Up

a) Blood Cultures and Infection Markers:

Repeat blood cultures and monitor CRP and WBC counts to assess treatment response, particularly in severe infections or sepsis.

b) Fluid Balance:

Monitor fluid intake and output, particularly in patients receiving IV fluids or those at risk of dehydration or renal impairment.

c) Functional and Cognitive Assessments:

Monitor functional status and mental state, as elderly patients with infections may experience delirium, which can persist after the infection resolves.

9. Complications of Infection

a) Sepsis and Septic Shock:

Infections can progress to sepsis, leading to multiorgan failure, hypotension, and death if not treated promptly.

b) Delirium:

Elderly patients, particularly those with cognitive impairment, are at high risk of developing delirium during an infection, which can lead to longer hospital stays and poor outcomes.

c) Chronic Functional Decline:

Infections in the elderly can result in permanent loss of function, reduced mobility, and the need for long-term care.

d) Hospital-Acquired Infections:

Elderly patients hospitalised for infections are at risk of acquiring further infections, such as pneumonia or *Clostridium difficile*, due to prolonged antibiotic use and weakened immunity.

Summary of Key Points for Infection in the Elderly

Infections are common and often present atypically in elderly patients, with symptoms like confusion, falls, or functional decline.

Diagnosis requires prompt investigation, including blood cultures, urine or sputum cultures, and imaging, to identify the source of infection and guide treatment.

First-line treatment involves empiric antibiotics, fluid resuscitation, and oxygen therapy, with targeted antibiotics once the causative organism is identified.

Regular monitoring is essential to assess response to treatment and prevent complications such as sepsis, delirium, or chronic functional decline.

45. Interface and Community Care

1. Detailed Definition of Interface and Community Care

Interface care refers to the transition and coordination of care between different healthcare settings, such as from hospital to home, or from primary care to specialised services.

Community care involves health and social services delivered in the home or community setting, aiming to support elderly individuals in living independently or with appropriate support. This model of care focuses on reducing hospital admissions, providing early intervention, and promoting quality of life in the elderly.

Key elements of community care include multidisciplinary team approaches, patient-centred care, social care services, and integration with primary and secondary healthcare systems. Community care is essential for managing chronic conditions, preventing hospital readmissions, and maintaining the well-being of older adults, especially those with frailty, dementia, or multiple comorbidities.

2. Common Presenting Needs and Issues

Elderly patients often require interface and community care for a range of health, social, and functional needs:

a) **Chronic Disease Management:**

Conditions such as heart failure, COPD, diabetes, and hypertension require regular monitoring and support in the community to avoid exacerbations and hospital admissions.

b) **Frailty and Functional Decline:**

Elderly individuals experiencing frailty may require assistance with activities of daily living (ADLs), mobility aids, and home adaptations to remain independent.

c) **Cognitive Impairment and Dementia:**

Patients with dementia or cognitive decline benefit from community-based memory clinics, cognitive stimulation therapy, and home support services to manage daily activities and prevent crisis admissions.

d) **Falls and Injury Prevention:**

Frequent falls or a history of falls in elderly patients often necessitate interventions such as home hazard assessments, physiotherapy, and falls prevention programs.

e) **Medication Management:**

Polypharmacy is common in older adults, and community services play a key role in medication reviews, compliance monitoring, and identifying potential drug interactions.

f) **Social Isolation:**

Many elderly individuals experience loneliness and social isolation, requiring support through social services, day centres, or voluntary organisations to maintain social engagement.

g) End-of-Life and Palliative Care:

Community care teams provide end-of-life care, allowing elderly patients to remain at home with dignity, through pain management, symptom control, and family support.

3. First-Line Assessments and Investigations

Comprehensive assessments are critical in determining the needs of elderly patients in the community, focusing on medical, functional, and social aspects. Key assessments include:

a) Comprehensive Geriatric Assessment (CGA):

What it examines: A holistic, multidisciplinary evaluation of the elderly person's medical, psychological, functional, and social status.

Purpose: Identifies needs related to frailty, chronic diseases, functional impairments, and social circumstances to develop a personalised care plan.

b) Medication Review:

What it examines: All current medications, including over-the-counter drugs, to identify potential side effects, interactions, or inappropriate medications.

Purpose: Reduces polypharmacy and optimises treatment to improve adherence and minimise adverse effects.

c) Falls Risk Assessment:

What it measures: Balance, gait, muscle strength, and home environment.

Purpose: Identifies patients at risk of falls and helps to implement preventive strategies, such as strength and balance exercises or home modifications.

d) Cognitive Screening Tools:

What it measures: Cognitive function using tools such as the Mini-Mental State Examination (MMSE) or the Montreal Cognitive Assessment (MoCA).

Purpose: Detects cognitive impairment or early-stage dementia, guiding referrals to memory clinics and community support services.

e) Social Care Needs Assessment:

What it examines: Evaluates the individual's ability to perform ADLs, home safety, and access to community resources.

Purpose: Identifies social care needs, such as personal care assistance, meal services, or home adaptations.

f) Advanced Care Planning:

What it examines: Patient preferences regarding end-of-life care, including Do Not Attempt Resuscitation (DNAR) orders and advance decisions.

Purpose: Ensures that care aligns with the patient's wishes and provides guidance to community care teams on end-of-life care.

4. Explanation of Assessments

a) **Comprehensive Geriatric Assessment (CGA):**

This multidisciplinary approach is used to evaluate an older adult's overall health and social situation, focusing on optimising function, independence, and quality of life. It includes input from doctors, nurses, physiotherapists, occupational therapists, and social workers, and helps coordinate care across different sectors.

b) **Falls Risk Assessment:**

Falls are a leading cause of injury in older adults, and assessing the risk of falls involves reviewing mobility, muscle strength, and home safety. Community-based falls prevention programs are implemented to reduce this risk.

c) **Social Care Needs Assessment:**

This assessment evaluates the patient's ability to manage independently at home and identifies the need for personal care assistance, home adaptations, or other social services.

5. Diagnostic Criteria for Community Care Needs

Community care needs are identified based on a combination of factors, including:

Functional Decline: Difficulty performing ADLs, such as dressing, bathing, or meal preparation.

Frailty: Presence of physical weakness, fatigue, and reduced resilience to health stressors, often assessed using tools like the Frailty Index.

Cognitive Impairment: Diagnosed through cognitive screening tools (e.g., MMSE, MoCA) and indicated by forgetfulness, confusion, or difficulty with daily tasks.

Chronic Conditions: Requiring ongoing management and monitoring to prevent exacerbations or complications (e.g., heart failure, diabetes).

Social Isolation: Identified through patient-reported loneliness, reduced social interaction, or lack of a support network.

NICE guidelines advocate for early identification of community care needs in elderly individuals to provide preventive care and support, reducing the need for hospital admissions and improving quality of life.

6. First-Line Therapy According to Guidelines

Management of elderly patients in the community focuses on delivering comprehensive care through multidisciplinary teams, reducing hospital admissions, and promoting independence:

a) **Multidisciplinary Team (MDT) Care:**

Action: Involves collaboration between GPs, nurses, physiotherapists, occupational therapists, social workers, and community pharmacists.

Outcome: Coordinates care across multiple disciplines to address medical, functional, and social needs.

b) Care at Home:

Action: Provide services such as personal care assistance, home adaptations (e.g., grab bars, ramps), and meal delivery.

Outcome: Supports elderly individuals in remaining independent in their own homes and reduces the risk of hospitalisation.

c) Chronic Disease Management Programs:

Action: Deliver community-based care for chronic conditions such as diabetes, COPD, and heart failure through regular monitoring, health education, and medication management.

Outcome: Prevents disease exacerbations, improves patient outcomes, and reduces emergency admissions.

d) Falls Prevention Programs:

Action: Provide strength and balance training, physiotherapy, home hazard assessments, and use of mobility aids.

Outcome: Reduces the risk of falls and fractures, maintaining mobility and independence.

e) Cognitive Support Services:

Action: Offer memory clinics, cognitive stimulation therapy, and community dementia support services.

Outcome: Helps patients with cognitive decline manage daily activities and provides support to caregivers.

f) Social Engagement and Voluntary Services:

Action: Facilitate social interaction through day centres, befriending services, and group activities to reduce social isolation.

Outcome: Improves mental well-being, reduces loneliness, and enhances quality of life.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Lack of Supportive Infrastructure: Without adequate support from family, caregivers, or social services, some patients may not be safe to remain at home and may require assisted living or nursing home placement.

b) Second-Line Therapy:

Hospital at Home Programs:

Indication: For patients with acute but stable conditions who would benefit from hospital-level care at home (e.g., intravenous antibiotics for infections).

Mechanism: Provides hospital-equivalent care in the home, reducing the need for hospital admissions.

Respite Care:

Indication: For caregivers of elderly individuals who need temporary relief, allowing time for recovery or self-care.

Mechanism: Temporary placement in a care facility or community-based respite services.

8. Routine Monitoring and Follow-Up

a) Regular Home Visits:

Community nurses, physiotherapists, or social workers should visit regularly to assess the patient's condition, mobility, and safety at home.

b) Care Plan Reviews:

Multidisciplinary teams should review care plans periodically to adjust for changes in the patient's health or functional status and update treatments accordingly.

c) Medication Monitoring:

Community pharmacists and nurses should regularly review medications for efficacy, adherence, and potential interactions, especially in patients with polypharmacy.

d) Chronic Disease Monitoring:

Ongoing assessment and monitoring for chronic diseases (e.g., diabetes, heart failure) should be carried out by community health teams to detect early signs of deterioration.

9. Complications of Inadequate Interface and Community Care

a) Increased Hospital Admissions:

Failure to provide appropriate community care can result in avoidable hospital admissions due to exacerbations of chronic conditions, falls, or infections.

b) Functional Decline:

Without sufficient home care or therapy, elderly patients may experience worsening of frailty and immobility, leading to further loss of independence.

c) Social Isolation:

Inadequate community care and support can increase feelings of loneliness, which is associated with poor mental and physical health outcomes, including depression and cognitive decline.

d) Caregiver Burnout:

Caregivers of elderly individuals may experience burnout if adequate community support (e.g., respite care or home health aides) is not provided, leading to physical and emotional stress.

Summary of Key Points for Interface and Community Care

Interface and community care involve the transition and coordination of healthcare services for elderly patients between different care settings, such as from hospital to home.

Key elements include multidisciplinary teams, chronic disease management, falls prevention, and support for cognitive impairment and social isolation.

Comprehensive geriatric assessments and social care needs assessments are essential in identifying the patient's health and functional status.

First-line management includes home care services, chronic disease monitoring, falls prevention programs, and social engagement initiatives.

Regular monitoring and follow-up ensure that care plans remain appropriate, reducing the risk of hospital admissions and maintaining independence.

46. Mental Capacity Concerns

1. Detailed Definition of Mental Capacity Concerns

Mental capacity refers to an individual's ability to make decisions regarding their own care, finances, and welfare. Concerns about mental capacity arise when an individual's cognitive abilities are impaired, which affects their ability to understand, retain, and weigh information needed to make informed decisions. This is particularly relevant in elderly patients who may experience cognitive decline due to conditions such as dementia, stroke, or delirium.

Under UK law, the **Mental Capacity Act 2005** outlines that every adult has the right to make their own decisions unless proven otherwise, and any assessment of mental capacity must be decision-specific and time-specific. A person is deemed to lack capacity if they are unable to:

Understand the information relevant to the decision.

Retain that information.

Use or weigh that information as part of the process of making the decision.

Communicate their decision (by any means).

2. Common Presenting Complaints and Symptoms

Concerns about mental capacity may arise in elderly patients when they present with the following:

a) **Cognitive Decline:**

Memory loss, confusion, or disorientation, particularly in patients with dementia, which affects their ability to make decisions about their care or finances.

b) **Acute Delirium:**

Sudden onset of confusion, agitation, or altered mental status, often triggered by an acute illness, infection, or hospitalisation, which may impair decision-making abilities.

c) Poor Judgment or Risk-Taking Behaviours:

Making decisions that are uncharacteristically unsafe or irrational, such as refusing necessary medical treatment or financial mismanagement.

d) Inconsistent Decision-Making:

Frequent changes in decisions, particularly regarding healthcare, living arrangements, or legal matters, which raises concerns about the individual's ability to weigh information effectively.

e) Difficulty Communicating Decisions:

Struggling to express choices or preferences clearly due to communication issues related to cognitive impairment, stroke, or aphasia.

f) Family or Caregiver Concerns:

Relatives or caregivers may express concerns about the individual's ability to manage daily affairs, particularly when it comes to complex decisions like managing finances or consent for medical treatment.

3. First-Line Investigations

Assessing mental capacity in elderly patients requires a structured approach, often involving multiple assessments and investigations to determine the extent of cognitive impairment and its impact on decision-making abilities.

a) Mental Capacity Assessment (MCA):

What it examines: A structured assessment focusing on the four key components of mental capacity (understanding, retaining, weighing information, and communicating decisions).

Purpose: Determines whether the individual can make specific decisions at the time the assessment is being conducted.

b) Cognitive Screening Tools:

Mini-Mental State Examination (MMSE):

What it measures: Orientation, memory, attention, language, and visuospatial skills.

Purpose: Detects cognitive impairment and provides an indication of the severity of dementia or other cognitive disorders.

Montreal Cognitive Assessment (MoCA):

What it measures: Executive function, attention, memory, and visuospatial abilities.

Purpose: More sensitive than the MMSE for detecting mild cognitive impairment and early dementia.

c) Delirium Screening Tools:

Confusion Assessment Method (CAM):

What it measures: Assesses for acute delirium, focusing on features such as acute onset, fluctuating course, inattention, and disorganised thinking.

Purpose: Identifies reversible causes of cognitive impairment that may affect mental capacity, such as infections or metabolic imbalances.

d) Physical Examination:

What it examines: A thorough neurological and general physical examination to identify any medical conditions (e.g., stroke, dehydration, electrolyte imbalances) that may contribute to cognitive impairment.

Purpose: Helps identify treatable causes of capacity concerns, such as delirium or acute illness.

e) Blood Tests and Imaging:

What they examine: Full blood count (FBC), urea and electrolytes (U&Es), liver function tests (LFTs), thyroid function tests, vitamin B12 levels, and brain imaging (CT or MRI).

Purpose: Identifies reversible causes of cognitive decline, such as hypothyroidism, vitamin deficiencies, or cerebrovascular disease, that could affect mental capacity.

f) Functional Assessment:

What it examines: The individual's ability to perform activities of daily living (ADLs), including managing finances, medications, and personal care.

Purpose: Assesses how cognitive impairment impacts daily functioning and decision-making abilities.

4. Explanation of Investigations

a) Mental Capacity Assessment (MCA):

The MCA is a structured legal framework used to assess whether an individual can make specific decisions. It is decision-specific and time-specific, meaning it must focus on the particular decision in question (e.g., consenting to surgery, managing finances) and be assessed at the time the decision needs to be made.

b) Cognitive Screening Tools (MMSE, MoCA):

These tools provide a quick and objective measure of cognitive function, helping to identify dementia or other cognitive disorders that may affect mental capacity. The MMSE is commonly used but may miss mild cognitive impairment, whereas the MoCA is more sensitive for early cognitive changes.

c) Confusion Assessment Method (CAM):

The CAM is a screening tool for delirium, which can cause acute confusion and impair decision-making abilities. Delirium is often reversible, and its identification is crucial in restoring capacity once the underlying cause is treated.

5. Diagnostic Criteria for Mental Capacity

Mental capacity is determined based on the four key elements as outlined by the **Mental Capacity Act 2005**:

Understanding: The individual must be able to understand the information relevant to the decision.

Retaining: The individual must be able to retain that information long enough to make a decision.

Weighing: The individual must be able to weigh the information and consider the consequences of different choices.

Communicating: The individual must be able to communicate their decision (verbally, in writing, or through other means).

If a person is unable to do any of the above, they are considered to lack the capacity to make that specific decision. Mental capacity must be assumed unless proven otherwise, and any decision made on behalf of the person must be in their best interests.

6. First-Line Therapy According to Guidelines

Management of mental capacity concerns involves addressing the underlying cause of cognitive impairment (if reversible) and ensuring that decisions made on behalf of the individual are in their best interests.

a) Treat Underlying Causes:

Delirium:

Action: Treat underlying causes of delirium (e.g., infections, dehydration, electrolyte imbalance).

Outcome: Restores cognitive function and capacity once the delirium resolves.

Cognitive Enhancers (e.g., Donepezil):

Indication: For patients with mild-to-moderate dementia, medications such as cholinesterase inhibitors may help improve cognitive function.

Outcome: Temporarily enhances cognitive function and may improve decision-making capacity.

b) Best Interests Decision-Making:

Action: When a person lacks capacity, decisions must be made in their best interests, involving family, caregivers, and healthcare professionals.

Outcome: Ensures that decisions align with the patient's values and wishes, even if they cannot make decisions themselves.

c) Lasting Power of Attorney (LPA):

Action: Encourage elderly patients to establish a **Lasting Power of Attorney (LPA)** for health and welfare or property and financial affairs while they still have capacity.

Outcome: Provides a legally appointed person the authority to make decisions on the individual's behalf if they lose capacity in the future.

d) **Advance Care Planning:**

Action: Encourage patients to create an **advance care plan** or **advance decision** to refuse treatment (ADRT) while they still have capacity.

Outcome: Ensures that their preferences for future medical care are respected, particularly in end-of-life situations.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Presumption of Capacity: It is important not to assume incapacity based on age, diagnosis, or appearance alone. Capacity should always be formally assessed and documented.

b) **Second-Line Therapy:**

Court of Protection:

Indication: For complex cases where there is disagreement or uncertainty about the patient's capacity or best interests, legal intervention from the **Court of Protection** may be necessary.

Mechanism: The court makes decisions on behalf of individuals who lack capacity, such as in disputes over medical treatment or financial decisions.

Independent Mental Capacity Advocate (IMCA):

Indication: When an individual without family or friends lacks capacity and important decisions need to be made (e.g., serious medical treatment), an IMCA is appointed to represent their interests.

8. Routine Monitoring and Follow-Up

a) **Regular Cognitive Assessments:**

Patients with conditions like dementia should undergo regular cognitive assessments to monitor for further decline in mental capacity and adjust care plans accordingly.

b) **Review of Advance Care Plans:**

Patients' advance care plans, LPAs, and best interests decisions should be reviewed periodically to ensure they remain appropriate as the individual's condition changes.

c) **Monitoring for Delirium:**

In elderly patients with fluctuating capacity due to delirium, close monitoring is essential to ensure that capacity is reassessed as their cognitive state improves.

9. Complications of Mental Capacity Loss

a) Inappropriate Medical Decisions:

If capacity is not assessed properly, patients may make decisions that are not in their best interests, such as refusing essential treatment.

b) Exploitation and Financial Abuse:

Elderly individuals with cognitive impairment may be vulnerable to financial exploitation or fraud if they lack the capacity to manage their finances.

c) Loss of Autonomy:

Without appropriate advance care planning or legal protections (e.g., LPA), individuals who lose capacity may have decisions made on their behalf that do not align with their wishes.

d) Social Isolation:

Patients who lose capacity may become socially isolated, particularly if they lose the ability to communicate their needs effectively.

Summary of Key Points for Mental Capacity Concerns in the Elderly

Mental capacity concerns arise when elderly individuals experience cognitive decline or impairment that affects their ability to make decisions about their care, finances, or welfare.

The **Mental Capacity Act 2005** provides a legal framework for assessing capacity and making decisions on behalf of those who lack capacity.

Management includes treating reversible causes of cognitive impairment, using cognitive enhancers when appropriate, and ensuring that best interests decisions are made for those who lack capacity.

Routine monitoring of cognitive function and regular review of care plans are essential to ensure that decisions continue to reflect the patient's needs and wishes.

47. Multifactorial Falls Management

1. Detailed Definition of Multifactorial Falls Management

Multifactorial falls management refers to the comprehensive approach to assessing and reducing the risk of falls in elderly patients by addressing multiple contributing factors. Falls are a major cause of injury, disability, and death in the elderly population and often result from a combination of intrinsic factors (e.g., muscle weakness, vision impairment, balance problems) and extrinsic factors (e.g., environmental hazards, medication side effects). The goal of multifactorial falls management is to identify and modify the risk factors for falls through interventions such as strength and balance exercises, home safety modifications, medication review, and vision correction.

Multifactorial falls management is typically overseen by a multidisciplinary team, including physicians, physiotherapists, occupational therapists, pharmacists, and social care professionals, to ensure a holistic and tailored approach to fall prevention.

2. Common Presenting Complaints and Symptoms

Elderly patients at risk of falls may present with:

a) Previous Falls or Near-Falls:

History of one or more falls in the past year, often unreported, or frequent “near-falls” where the patient almost trips or loses balance.

b) Impaired Balance or Gait:

Difficulty walking, unsteady gait, or need for walking aids such as canes or walkers.

c) Muscle Weakness:

Generalised muscle weakness, particularly in the lower limbs, which makes it difficult to stand, walk, or climb stairs.

d) Dizziness or Lightheadedness:

Sensations of dizziness or faintness, particularly upon standing (potentially due to orthostatic hypotension), increasing the risk of falls.

e) Visual Impairment:

Difficulty seeing obstacles or uneven surfaces, which may contribute to tripping or misjudging steps or furniture.

f) Postural Instability:

Difficulty maintaining posture when standing or walking, often due to neurological or musculoskeletal issues.

g) Incontinence:

Urinary urgency or incontinence can lead to rushing to the toilet, increasing the risk of falls.

3. First-Line Investigations

Assessing fall risk in elderly patients involves a thorough evaluation of medical, functional, and environmental factors. Key assessments include:

a) Comprehensive Falls History:

What it examines: Details of previous falls, including the circumstances, frequency, and any injuries sustained.

Purpose: Helps identify patterns of falls and contributing factors, such as environmental hazards or specific triggers (e.g., standing up quickly).

b) Timed Up and Go (TUG) Test:

What it measures: Time taken for the patient to stand from a chair, walk 3 metres, turn around, and return to the chair.

Purpose: Assesses mobility, balance, and gait. A time of >12 seconds indicates increased fall risk.

c) Gait and Balance Assessment:

What it examines: Observation of walking pattern, posture, and use of walking aids.

Purpose: Identifies abnormalities in gait or balance that increase the risk of falls.

d) Physical Examination:

What it examines: Muscle strength, joint function, and neurological status.

Purpose: Detects musculoskeletal or neurological impairments that may affect mobility and balance.

e) Medication Review:

What it examines: A thorough review of all prescribed, over-the-counter, and herbal medications.

Purpose: Identifies medications that may contribute to falls (e.g., sedatives, antihypertensives, or medications with anticholinergic effects).

f) Orthostatic Blood Pressure Measurement:

What it measures: Blood pressure is measured while lying down and then again after standing.

Purpose: Detects orthostatic hypotension, a common cause of dizziness and falls in elderly patients.

g) Vision and Hearing Tests:

What it examines: Assesses for visual impairments (e.g., cataracts, glaucoma) or hearing loss that could contribute to falls.

Purpose: Detects sensory deficits that impair spatial awareness or balance.

h) Home Environment Assessment:

What it examines: The patient's living space for fall hazards such as loose rugs, poor lighting, or lack of handrails.

Purpose: Identifies extrinsic risk factors that can be modified to reduce fall risk.

4. Explanation of Investigations

a) Timed Up and Go (TUG) Test:

This quick and objective test measures a person's mobility and risk of falling. A result of more than 12 seconds suggests significant impairment in balance and gait, indicating a high fall risk.

b) Medication Review:

Many medications, particularly sedatives, antihypertensives, and anticholinergics, increase the risk of falls by causing dizziness, sedation, or orthostatic hypotension. A thorough review helps identify medications that can be adjusted or discontinued to reduce fall risk.

c) Home Environment Assessment:

A home assessment by an occupational therapist identifies hazards in the living environment

that can contribute to falls. Recommendations for home modifications, such as installing grab bars, improving lighting, or removing clutter, can significantly reduce fall risk.

5. Diagnostic Criteria for Falls Risk

Falls risk is identified based on a combination of factors, including:

History of Previous Falls: A key indicator of future fall risk, especially if there have been multiple falls in the past year.

Mobility Impairments: Difficulty walking, poor balance, or slow gait speed as measured by the TUG test or gait and balance assessments.

Visual Impairment: Reduced vision due to conditions like cataracts or macular degeneration.

Postural Hypotension: Diagnosed with a drop in systolic blood pressure of ≥ 20 mmHg or diastolic blood pressure of ≥ 10 mmHg upon standing.

Polypharmacy: Use of multiple medications, particularly those that affect balance or cognition.

According to **NICE guidelines**, a comprehensive multifactorial risk assessment should be performed for all elderly patients who have experienced a fall or are at risk of falling.

6. First-Line Therapy According to Guidelines

Management of falls in elderly patients requires a multifactorial approach, targeting both intrinsic and extrinsic risk factors. Key interventions include:

a) Strength and Balance Training:

Action: Engage patients in exercise programs designed to improve muscle strength, balance, and coordination (e.g., physiotherapy, Tai Chi).

Outcome: Reduces muscle weakness, improves balance, and lowers the risk of falls. These programs are highly effective in preventing future falls.

b) Medication Review and Adjustment:

Action: Discontinue or adjust medications that increase the risk of falls, such as sedatives, antihypertensives, or diuretics.

Outcome: Reduces dizziness, orthostatic hypotension, and sedation, which can all contribute to falls.

c) Home Safety Modifications:

Action: Remove trip hazards (e.g., loose rugs), install grab bars and handrails, improve lighting, and ensure safe bathroom facilities.

Outcome: Reduces the risk of falls by creating a safer living environment.

d) Vision and Hearing Correction:

Action: Prescribe glasses or contact lenses for visual impairments and hearing aids for hearing loss.

Outcome: Improves spatial awareness, reduces the likelihood of tripping, and enhances balance through better sensory input.

e) **Management of Orthostatic Hypotension:**

Action: Encourage adequate fluid intake, gradual postural changes, and compression stockings to improve venous return.

Outcome: Prevents sudden drops in blood pressure upon standing, reducing the risk of dizziness and falls.

f) **Footwear and Podiatry Services:**

Action: Provide appropriate, well-fitting footwear and treat foot problems such as corns or bunions.

Outcome: Improves gait and balance, reducing the risk of falls due to foot pain or unstable footwear.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Sedative Medications: Avoid long-term use of sedatives or hypnotics in elderly patients, as they increase the risk of falls by causing drowsiness and impaired coordination.

b) **Second-Line Therapy:**

Occupational Therapy:

Indication: For patients who need help with daily activities due to functional limitations or who are at risk of falls at home.

Mechanism: Occupational therapists provide training, adaptive equipment, and environmental modifications to enhance safety and independence.

Vitamin D Supplementation:

Indication: For patients with vitamin D deficiency or those at risk of falls due to weak bones and muscles.

Mechanism: Improves bone health and muscle function, reducing the risk of falls and fractures.

8. Routine Monitoring and Follow-Up

a) **Regular Falls Risk Assessments:**

Patients should be reassessed periodically, especially after any new falls, to update their care plan and adjust interventions as needed.

b) Monitoring Medication Adjustments:

Review medications regularly, particularly when new medications are introduced or doses are changed, to monitor for any adverse effects that may increase the risk of falls.

c) Home Reassessments:

After any changes in the patient's functional status, repeat home assessments to ensure the living environment remains safe and free of fall hazards.

9. Complications of Falls

a) Fractures and Injuries:

Falls frequently lead to fractures, particularly of the hip, wrist, or spine, resulting in pain, immobility, and often requiring surgery.

b) Head Trauma:

Falls can cause head injuries, including concussions or subdural haematomas, which are particularly dangerous in elderly patients, especially those on anticoagulants.

c) Hospitalisation and Long-Term Care:

Recurrent falls may lead to hospitalisation, prolonged recovery periods, and a loss of independence, often requiring long-term care placement.

d) Fear of Falling:

After experiencing a fall, many elderly individuals develop a fear of falling again, leading to reduced mobility, social isolation, and further physical decline (the "post-fall syndrome").

Summary of Key Points for Multifactorial Falls Management in the Elderly

Falls in elderly patients are often multifactorial, involving a combination of intrinsic factors (e.g., muscle weakness, balance problems) and extrinsic factors (e.g., home hazards, medication side effects).

A thorough assessment, including a **Comprehensive Falls History, TUG Test, and Medication Review**, is essential to identify all contributing factors.

First-line management includes strength and balance training, home safety modifications, medication review, and addressing orthostatic hypotension and sensory impairments.

Regular follow-up and reassessment are essential to prevent falls, improve mobility, and maintain independence.

48. Orthogeriatrics

1. Detailed Definition of Orthogeriatrics

Orthogeriatrics is the branch of medicine that focuses on the care of elderly patients with orthopaedic conditions, particularly those who have sustained fractures. Orthogeriatric care involves a multidisciplinary approach that combines the expertise of orthopaedic surgeons, geriatricians, physiotherapists, occupational therapists, and nurses to optimise the

management of frail elderly patients who often have complex medical needs. The goal is to improve outcomes by addressing both the surgical and medical needs of these patients, managing comorbidities, preventing complications, and promoting early mobilisation and rehabilitation.

The most common focus in orthogeriatrics is on **hip fractures**, but other fractures, such as those of the wrist, spine, and pelvis, are also commonly managed.

2. Common Presenting Complaints and Symptoms

Elderly patients requiring orthogeriatric care often present with the following:

a) **Fractures Following a Fall:**

Most commonly **hip fractures**, but also wrist, vertebral, or pelvic fractures, typically following a low-impact fall due to frailty, osteoporosis, or balance issues.

b) **Pain and Immobility:**

Severe pain at the site of the fracture, particularly in the hip, pelvis, or wrist.

Inability to bear weight or walk in the case of hip or pelvic fractures.

c) **Previous Falls or Fear of Falling:**

History of recent falls, sometimes without reported trauma due to fear of immobility, muscle weakness, or poor balance.

d) **Pre-existing Comorbidities:**

Chronic conditions such as osteoporosis, heart failure, dementia, diabetes, or chronic obstructive pulmonary disease (COPD), which complicate the management of fractures and rehabilitation.

e) **Functional Decline:**

Reduced ability to perform activities of daily living (ADLs), sometimes preceding the injury, due to frailty or chronic disease.

3. First-Line Investigations

Comprehensive assessment in orthogeriatric care includes evaluating the fracture and the patient's overall health status, with attention to their comorbidities and functional abilities:

a) **X-ray** (of the affected area):

What it examines: Imaging of the site of injury, typically the hip, wrist, or spine.

Purpose: Confirms the presence, type, and location of the fracture and guides treatment decisions (e.g., surgical or conservative management).

b) **CT or MRI (if indicated):**

What it examines: Detailed imaging to assess more complex fractures, such as pelvic or vertebral fractures.

Purpose: Provides a clearer understanding of fracture patterns, especially in cases where X-rays are inconclusive or where occult fractures are suspected.

c) **Blood Tests:**

Full Blood Count (FBC):

Purpose: Assesses for anaemia, infection, or other haematological conditions that may affect surgery or recovery.

Urea & Electrolytes (U&Es):

Purpose: Evaluates kidney function, which may be important for surgery planning and managing fluids during recovery.

Bone Profile (calcium, phosphate, vitamin D):

Purpose: Assesses for underlying metabolic bone disease such as osteoporosis or osteomalacia, which predispose elderly patients to fractures.

d) **Electrocardiogram (ECG):**

What it examines: Heart rhythm and electrical activity.

Purpose: Detects arrhythmias or ischaemic heart disease that may complicate anaesthesia or recovery from surgery.

e) **Cognitive Assessment (e.g., MMSE or MoCA):**

What it examines: Cognitive function, particularly in patients with dementia or delirium.

Purpose: Identifies cognitive impairments that may affect consent to surgery, postoperative recovery, or rehabilitation.

f) **Comprehensive Geriatric Assessment (CGA):**

What it examines: A holistic evaluation of the patient's medical, functional, cognitive, and social status.

Purpose: Guides multidisciplinary care planning, particularly for managing frailty, comorbidities, and rehabilitation needs.

4. Explanation of Investigations

a) **X-ray:**

An X-ray is the first-line imaging used to diagnose fractures. In the case of hip fractures, it helps differentiate between intracapsular and extracapsular fractures, which have different surgical management approaches.

b) **Comprehensive Geriatric Assessment (CGA):**

A CGA is a multidisciplinary tool that evaluates the patient's medical conditions, functional status, and social circumstances. This is key in orthogeriatric care to identify comorbidities

(e.g., frailty, dementia, malnutrition) that may affect recovery and to develop a rehabilitation plan.

5. Diagnostic Criteria for Orthogeriatric Care Needs

Orthogeriatric patients are typically identified based on:

Fractures, Particularly Hip Fractures: Diagnosed with X-rays or CT scans, hip fractures are a common indication for orthogeriatric care, especially in patients over the age of 65.

Comorbidities and Frailty: Elderly patients with significant comorbidities (e.g., dementia, heart failure, osteoporosis) or frailty that complicates their care and rehabilitation.

Impaired Mobility or Functional Decline: Reduced ability to perform ADLs, especially after sustaining a fracture, indicating the need for multidisciplinary intervention.

According to **NICE guidelines**, all elderly patients with hip fractures should be managed through an orthogeriatric care pathway, ensuring that both surgical and medical aspects of their care are optimised.

6. First-Line Therapy According to Guidelines

Management of elderly patients with fractures focuses on both the surgical repair of the fracture and the comprehensive care of the individual's medical and functional needs:

a) Surgical Management of Fractures:

Hip Fracture Repair (e.g., Hemiarthroplasty, Total Hip Replacement, or Internal Fixation):

Action: Surgery is the standard treatment for most hip fractures, depending on the type of fracture and the patient's overall health status.

Outcome: Aims to restore mobility and reduce the risk of long-term complications such as immobility, pressure sores, or deep vein thrombosis (DVT).

Spinal or Pelvic Fracture Management:

Action: Depending on the severity and stability of the fracture, management may involve surgical fixation or conservative treatment (e.g., bed rest, pain management).

b) Multidisciplinary Postoperative Care:

Early Mobilisation:

Action: Initiate mobilisation as early as possible, typically within 24 hours of surgery, with the support of physiotherapists.

Outcome: Reduces the risk of complications such as DVT, pneumonia, and pressure sores, while improving long-term functional outcomes.

Pain Management:

Action: Provide adequate analgesia, often using a multimodal approach (e.g., paracetamol, opioids, regional anaesthesia) to control pain and facilitate rehabilitation.

Outcome: Improves comfort, promotes early mobilisation, and enhances participation in rehabilitation.

Prevention of Delirium:

Action: Monitor for delirium, which is common in elderly patients after surgery, especially those with pre-existing cognitive impairments. Ensure adequate hydration, nutrition, and sleep, and reduce sensory deprivation.

Outcome: Minimises cognitive decline and enhances recovery by addressing reversible causes of delirium.

c) Rehabilitation and Physiotherapy:

Action: Initiate tailored physiotherapy focusing on improving strength, balance, and mobility.

Outcome: Promotes functional recovery, prevents complications related to immobility, and aims to restore independence in daily activities.

d) Management of Osteoporosis:

Action: Provide bone-strengthening treatments (e.g., bisphosphonates, calcium, vitamin D) in patients diagnosed with osteoporosis to prevent future fractures.

Outcome: Reduces the risk of subsequent fractures by improving bone density and strength.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Non-operative Management for Hip Fractures: In most cases, surgery is indicated for hip fractures, but non-operative management may be considered in patients who are too frail for surgery or who have limited life expectancy.

b) Second-Line Therapy:

Long-Term Rehabilitation:

Indication: For patients who are slow to recover or have significant functional limitations, extended rehabilitation in a specialised unit may be necessary.

Mechanism: Provides intensive physiotherapy, occupational therapy, and nursing care over a longer period to maximise recovery.

Multifactorial Falls Prevention:

Indication: For patients who have had a fracture due to a fall, ongoing falls prevention programs are important.

Mechanism: Includes strength and balance training, home safety assessments, and review of medications that may contribute to falls.

8. Routine Monitoring and Follow-Up

a) **Postoperative Follow-Up:**

Patients should be regularly assessed after surgery to monitor wound healing, assess mobility, and check for signs of complications such as infection or DVT.

b) **Cognitive Monitoring:**

For patients at risk of delirium or cognitive decline, regular cognitive assessments should be performed during and after the recovery period.

c) **Bone Health Monitoring:**

Patients diagnosed with osteoporosis should have regular follow-up to monitor their bone health and adjust treatments accordingly.

d) **Rehabilitation Progress:**

Physiotherapists and occupational therapists should monitor rehabilitation progress, adjusting therapy plans as necessary to support continued recovery.

9. Complications of Fractures in Elderly Patients

a) **Delirium:**

Postoperative delirium is common in elderly patients and can lead to prolonged hospital stays, increased morbidity, and poorer functional outcomes.

b) **Deep Vein Thrombosis (DVT) and Pulmonary Embolism (PE):**

Prolonged immobility increases the risk of DVT and PE, which can be life-threatening. Early mobilisation and anticoagulation therapy help reduce this risk.

c) **Pressure Sores:**

Immobility following fractures increases the risk of developing pressure ulcers, particularly in frail elderly patients.

d) **Pneumonia:**

Prolonged bed rest and immobility, particularly in patients with pre-existing respiratory conditions, increase the risk of pneumonia.

e) **Chronic Pain and Loss of Mobility:**

Failure to rehabilitate properly can result in long-term pain, reduced mobility, and loss of independence.

Summary of Key Points for Orthogeriatric Care

Orthogeriatric care is the management of elderly patients with fractures, particularly focusing on the surgical repair of fractures and the holistic management of the patient's medical and functional needs.

A **Comprehensive Geriatric Assessment** and **multidisciplinary approach** are essential to managing comorbidities, preventing complications, and ensuring early mobilisation and rehabilitation.

First-line management includes surgery for most fractures (especially hip fractures), pain control, early mobilisation, and postoperative care aimed at reducing the risk of complications like delirium, DVT, and pneumonia.

Ongoing rehabilitation, osteoporosis management, and falls prevention are critical to improving long-term outcomes and preventing future fractures.

49. Osteoporosis

1. Detailed Definition of Osteoporosis

Osteoporosis is a skeletal disorder characterised by decreased bone density and deterioration of bone tissue, leading to fragile bones and an increased risk of fractures. It commonly affects elderly individuals, particularly postmenopausal women and older men, due to age-related bone loss. Osteoporosis is often asymptomatic until a fracture occurs, with the most common fracture sites being the hip, spine, and wrist. The condition results from an imbalance between bone resorption and bone formation, where bone breakdown outpaces bone rebuilding.

Osteoporosis is diagnosed when bone mineral density (BMD) is 2.5 standard deviations or more below the mean peak bone mass, defined as a T-score of ≤ -2.5 , typically measured by dual-energy X-ray absorptiometry (DEXA).

2. Common Presenting Complaints and Symptoms

Osteoporosis is often referred to as a "silent disease" because it typically presents with no symptoms until a fracture occurs. However, patients may present with:

a) **Fractures:**

Fragility fractures that occur with minimal trauma, particularly in the hip, spine, and wrist.

Vertebral compression fractures may result in acute back pain and loss of height.

b) **Chronic Back Pain:**

Due to vertebral compression fractures, often resulting in kyphosis (excessive forward curvature of the spine) and difficulty standing or walking.

c) **Loss of Height:**

Gradual reduction in height due to compression fractures in the vertebrae.

d) **Stooped Posture (Kyphosis):**

Forward curvature of the spine due to vertebral fractures, giving a stooped or hunched appearance.

e) **Decreased Mobility:**

As a result of fractures and pain, leading to reduced physical activity and further weakening of the bones.

3. First-Line Investigations

Diagnosis of osteoporosis and evaluation of fracture risk require a combination of clinical assessments and imaging:

a) **Dual-Energy X-ray Absorptiometry (DEXA) Scan:**

What it measures: Bone mineral density (BMD) at the hip and spine, providing a T-score.

Purpose: Diagnoses osteoporosis when the T-score is ≤ -2.5 and helps assess fracture risk.

b) **FRAX Tool (Fracture Risk Assessment Tool):**

What it examines: A clinical tool that calculates the 10-year probability of a major osteoporotic fracture based on factors such as age, sex, weight, history of fractures, smoking, alcohol use, and use of glucocorticoids.

Purpose: Assesses fracture risk in individuals and guides decisions on treatment.

c) **X-ray of Suspected Fracture Sites:**

What it examines: Identifies fractures, particularly in the spine, hip, or wrist.

Purpose: Detects fragility fractures that may not be clinically obvious, especially vertebral compression fractures.

d) **Blood Tests:**

What they measure: Serum calcium, phosphate, vitamin D levels, and parathyroid hormone (PTH).

Purpose: Rules out secondary causes of osteoporosis, such as hyperparathyroidism, vitamin D deficiency, or malabsorption disorders.

e) **Bone Turnover Markers** (optional):

What they measure: Levels of markers such as alkaline phosphatase, osteocalcin, or C-terminal telopeptide.

Purpose: Provides information on bone resorption and formation activity, helping assess the response to osteoporosis treatment.

4. Explanation of Investigations

a) **DEXA Scan:**

This is the gold standard for diagnosing osteoporosis and assessing fracture risk. It provides a T-score, comparing the patient's BMD to that of a young, healthy adult. A T-score of ≤ -2.5 indicates osteoporosis, while a T-score between -1.0 and -2.5 indicates osteopenia (low bone mass, but not severe enough to be classified as osteoporosis).

b) **FRAX Tool:**

The FRAX tool is used to estimate an individual's 10-year risk of a major osteoporotic fracture, considering both clinical risk factors and BMD results (if available). It helps guide treatment decisions, especially in those with osteopenia.

c) **Blood Tests:**

Blood tests are important for ruling out secondary causes of osteoporosis. Vitamin D deficiency, hypercalcaemia, or hyperparathyroidism can contribute to bone loss, and correcting these underlying issues is critical in managing osteoporosis.

5. Diagnostic Criteria for Osteoporosis

Osteoporosis is diagnosed based on BMD measurements and clinical risk factors:

T-score ≤ -2.5 on a DEXA scan confirms a diagnosis of osteoporosis.

Osteopenia is diagnosed when the T-score is between -1.0 and -2.5, indicating low bone mass.

Fragility Fractures: A history of fractures following minimal trauma (e.g., a fall from standing height) strongly suggests osteoporosis, even in the absence of a DEXA scan result.

NICE guidelines recommend using the FRAX tool in conjunction with BMD testing to assess fracture risk in patients with low bone mass and guide treatment decisions.

6. First-Line Therapy According to Guidelines

The primary goals of osteoporosis treatment are to reduce the risk of fractures, maintain bone strength, and improve quality of life. Management includes pharmacological and lifestyle interventions:

a) **Pharmacological Treatment:**

Bisphosphonates (e.g., Alendronate, Risedronate, Zoledronate):

Action: Inhibit bone resorption by osteoclasts, slowing bone loss.

Dose: Alendronate 70 mg orally once a week or Zoledronate 5 mg IV annually.

Outcome: Reduces the risk of vertebral, hip, and other fractures.

Denosumab:

Action: A monoclonal antibody that inhibits RANKL, preventing osteoclast formation and bone resorption.

Dose: 60 mg subcutaneously every 6 months.

Outcome: Reduces the risk of fractures, particularly in patients intolerant to bisphosphonates.

Calcium and Vitamin D Supplements:

Action: Provide the necessary nutrients for bone health.

Dose: 1,000-1,200 mg of calcium and 800-1,000 IU of vitamin D daily.

Outcome: Supports bone formation and prevents fractures, particularly in those with vitamin D deficiency.

Teriparatide (Parathyroid Hormone Analogue):

Action: Stimulates bone formation by increasing osteoblast activity.

Dose: 20 mcg subcutaneously daily (for up to 24 months).

Outcome: Used in patients with severe osteoporosis or multiple fractures who are not responding to other treatments.

Hormone Replacement Therapy (HRT) (in postmenopausal women):

Action: Increases bone density by replacing oestrogen, which decreases after menopause.

Outcome: Effective in preventing bone loss but typically reserved for younger postmenopausal women due to the associated risks (e.g., breast cancer, cardiovascular disease).

b) Lifestyle Modifications:

Weight-Bearing and Resistance Exercise:

Action: Regular physical activity, particularly weight-bearing exercises (e.g., walking, dancing) and resistance training.

Outcome: Strengthens bones and muscles, reducing fracture risk.

Smoking Cessation and Alcohol Reduction:

Action: Quit smoking and limit alcohol intake to <2 units per day.

Outcome: Reduces bone loss and improves overall bone health.

Fall Prevention:

Action: Implement home safety modifications, use appropriate footwear, and consider balance exercises (e.g., Tai Chi) to reduce the risk of falls.

Outcome: Prevents fractures by reducing the likelihood of falls.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Bisphosphonates: Should be avoided in patients with severe renal impairment (eGFR <35 mL/min), hypocalcaemia, or oesophageal disorders due to the risk of oesophagitis.

b) Second-Line Therapy:

Raloxifene (Selective Oestrogen Receptor Modulator - SERM):

Indication: Used in postmenopausal women who are at increased risk of vertebral fractures but are intolerant of bisphosphonates.

Mechanism: Mimics oestrogen's effects on bone, reducing bone resorption.

Outcome: Reduces the risk of vertebral fractures but does not reduce hip fracture risk.

Romosozumab:

Indication: For postmenopausal women with severe osteoporosis who have not responded to other treatments.

Mechanism: Inhibits sclerostin, increasing bone formation and reducing resorption.

Outcome: Increases bone density and reduces the risk of fractures.

8. Routine Monitoring and Follow-Up

a) Repeat DEXA Scans:

Patients should have follow-up DEXA scans every 2-3 years to monitor BMD and assess the effectiveness of treatment.

b) Monitoring for Adverse Effects:

Regularly monitor patients on bisphosphonates for side effects, such as gastrointestinal symptoms or rare complications like osteonecrosis of the jaw (particularly with IV bisphosphonates).

c) Bone Turnover Markers:

In some cases, bone turnover markers can be monitored to assess response to treatment.

d) Fracture Risk Assessment:

Reassess fracture risk regularly, especially after new fractures, changes in medication, or significant health changes.

9. Complications of Osteoporosis

a) Fractures:

The most common and serious complication of osteoporosis. Hip fractures often lead to loss of independence, disability, and increased mortality, while vertebral fractures can cause chronic pain and kyphosis.

b) Chronic Pain:

Vertebral fractures can lead to long-term back pain and disability, affecting quality of life and mobility.

c) Kyphosis and Height Loss:

Multiple vertebral fractures can cause a stooped posture (kyphosis) and significant loss of height.

d) Immobilisation and Disability:

Fractures, especially hip fractures, can lead to prolonged immobility, increasing the risk of complications such as deep vein thrombosis (DVT), pressure sores, and pneumonia.

Summary of Key Points for Osteoporosis

Osteoporosis is a condition characterised by reduced bone density and an increased risk of fractures, particularly in elderly patients.

Diagnosis is primarily based on BMD testing using DEXA scans, with a T-score of ≤ -2.5 indicating osteoporosis.

First-line treatment includes bisphosphonates, calcium and vitamin D supplementation, and lifestyle modifications such as exercise and fall prevention.

Regular monitoring, including follow-up DEXA scans and fracture risk assessments, is essential to managing osteoporosis and preventing fractures.

50. Parkinson's Disease – Comprehensive Revision Notes

1. Detailed Definition of Parkinson's Disease

Parkinson's disease (PD) is a progressive neurodegenerative disorder that primarily affects movement. It results from the loss of dopamine-producing neurons in the substantia nigra, a part of the brain that controls motor function. The decrease in dopamine leads to characteristic motor symptoms, including tremors, bradykinesia (slowness of movement), rigidity, and postural instability. As the disease progresses, non-motor symptoms, such as cognitive decline, depression, autonomic dysfunction, and sleep disturbances, often develop. Parkinson's disease typically affects individuals over the age of 60 but can occur earlier in some cases.

2. Common Presenting Complaints and Symptoms

Patients with Parkinson's disease may present with both **motor** and **non-motor** symptoms:

a) Motor Symptoms:

Resting Tremor:

Usually begins in one hand or arm and is often described as a "pill-rolling" tremor. It occurs at rest and may improve with voluntary movement.

Bradykinesia (Slowness of Movement):

Difficulty initiating and performing voluntary movements, such as walking or rising from a chair. Patients may exhibit a shuffling gait with short steps.

Muscle Rigidity:

Increased muscle tone, often described as "lead-pipe" or "cogwheel" rigidity when the limbs are moved by an examiner.

Postural Instability:

Problems with balance and coordination, leading to falls and difficulty maintaining an upright posture.

Micrographia:

Handwriting becomes smaller and more cramped as the disease progresses.

b) Non-Motor Symptoms:

Cognitive Impairment:

Difficulty with attention, planning, and memory. In later stages, dementia may develop.

Mood Disorders:

Depression, anxiety, and apathy are common in patients with Parkinson's disease.

Autonomic Dysfunction:

Symptoms may include constipation, urinary incontinence, orthostatic hypotension, and erectile dysfunction.

Sleep Disturbances:

Insomnia, vivid dreams, restless legs syndrome, and REM sleep behaviour disorder (acting out dreams during sleep).

Hyposmia (Reduced Sense of Smell):

Often an early symptom of Parkinson's disease, sometimes predating the motor symptoms by years.

3. First-Line Investigations

Parkinson's disease is primarily diagnosed based on clinical features, but additional investigations may be needed to rule out other causes of parkinsonism.

a) Clinical Diagnosis (UK Parkinson's Disease Society Brain Bank Criteria):

What it examines: Diagnosis is based on the presence of **bradykinesia** plus at least one of the following:

Resting tremor.

Muscular rigidity.

Postural instability (not caused by primary visual, vestibular, cerebellar, or proprioceptive dysfunction).

Purpose: Confirms the diagnosis of idiopathic Parkinson's disease, while excluding other causes of parkinsonism.

b) Levodopa Trial:

What it examines: Response to a trial of levodopa (the main drug used to treat PD).

Purpose: Improvement in motor symptoms after starting levodopa supports the diagnosis of Parkinson's disease.

c) DaTSCAN (Dopamine Transporter Scan):

What it examines: Imaging that measures dopamine transporter levels in the brain.

Purpose: Differentiates Parkinson's disease from other conditions that mimic parkinsonism, such as drug-induced parkinsonism or essential tremor.

d) **MRI or CT Brain Scan** (if needed):

What it examines: Brain structure.

Purpose: Used to rule out other causes of parkinsonism, such as vascular parkinsonism or normal pressure hydrocephalus. Brain imaging in Parkinson's disease is typically normal.

4. Explanation of Investigations

a) **Clinical Diagnosis Using UK Brain Bank Criteria:**

The clinical diagnosis of Parkinson's disease is based on specific motor symptoms, such as bradykinesia and resting tremor, and is supported by a good response to dopaminergic medications like levodopa. Non-motor symptoms, such as sleep disturbances or depression, also help differentiate PD from other parkinsonian syndromes.

b) **DaTSCAN:**

This imaging technique helps confirm the loss of dopamine-producing neurons in the brain by visualising the dopamine transporter. It is used when the diagnosis is uncertain and to rule out other conditions that mimic PD.

5. Diagnostic Criteria for Parkinson's Disease

The **UK Parkinson's Disease Society Brain Bank Criteria** are commonly used to diagnose Parkinson's disease. The diagnosis requires:

Bradykinesia (slowness of movement) and at least one of the following:

Resting tremor.

Muscular rigidity.

Postural instability.

Exclusion of other causes of parkinsonism, such as drug-induced parkinsonism, vascular parkinsonism, or atypical parkinsonian syndromes (e.g., multiple system atrophy, progressive supranuclear palsy).

6. First-Line Therapy According to Guidelines

The treatment of Parkinson's disease focuses on relieving symptoms, particularly motor symptoms, while also addressing non-motor issues. Treatment is often initiated based on the severity of symptoms and their impact on daily life.

a) **Pharmacological Treatment:**

Levodopa (e.g., Co-Beneldopa, Co-Careldopa):

Action: Levodopa is converted to dopamine in the brain, compensating for the dopamine deficiency.

Dose: Typically started at a low dose and titrated up as needed, often in combination with a decarboxylase inhibitor to reduce peripheral side effects.

Outcome: Levodopa is the most effective treatment for improving motor symptoms, including bradykinesia and rigidity. Long-term use may be associated with motor fluctuations and dyskinesias (involuntary movements).

Dopamine Agonists (e.g., Pramipexole, Ropinirole):

Action: Stimulate dopamine receptors in the brain.

Outcome: Useful as initial therapy in younger patients to delay the need for levodopa or as adjunctive therapy. May cause side effects such as impulse control disorders (e.g., gambling, hypersexuality).

Monoamine Oxidase-B (MAO-B) Inhibitors (e.g., Selegiline, Rasagiline):

Action: Inhibits the breakdown of dopamine in the brain.

Outcome: May be used as monotherapy in early-stage PD or in combination with levodopa to reduce motor fluctuations.

Catechol-O-Methyltransferase (COMT) Inhibitors (e.g., Entacapone):

Action: Inhibits the breakdown of levodopa, prolonging its action.

Outcome: Used in combination with levodopa to reduce "wearing-off" symptoms and prolong its effectiveness.

b) Non-Pharmacological Treatments:

Physiotherapy:

Action: Improves mobility, balance, and muscle strength.

Outcome: Helps reduce falls, maintain mobility, and manage gait difficulties.

Occupational Therapy:

Action: Assists patients in managing daily activities and maintaining independence.

Outcome: Supports patients in adapting to the challenges posed by motor and non-motor symptoms.

Speech and Language Therapy:

Action: Helps with speech clarity (hypophonia) and swallowing difficulties (dysphagia).

Outcome: Improves communication and reduces the risk of aspiration pneumonia.

c) Deep Brain Stimulation (DBS):

Indication: For patients with advanced Parkinson's disease who have significant motor fluctuations or dyskinesias that are poorly controlled by medication.

Mechanism: Involves surgical implantation of electrodes in the brain to stimulate specific areas involved in motor control.

Outcome: Can provide significant relief from motor symptoms and reduce the need for high doses of medication.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Dopamine Agonists: Should be used cautiously in elderly patients due to the increased risk of side effects such as hallucinations, somnolence, and impulse control disorders.

b) Second-Line Therapy:

Amantadine:

Indication: May be used to treat dyskinesias in patients on long-term levodopa therapy.

Mechanism: Increases dopamine release and reduces dyskinesias.

Outcome: Provides additional control of motor symptoms but may cause side effects such as confusion or hallucinations.

Apomorphine:

Indication: Used for severe motor fluctuations as a "rescue" therapy for sudden "off" periods in advanced PD.

Mechanism: A potent dopamine agonist that can be given via subcutaneous injection or continuous infusion.

Outcome: Provides rapid relief of severe "off" episodes but requires careful monitoring for side effects.

8. Routine Monitoring and Follow-Up

a) Regular Medication Review:

Patients should have their medication regimen reviewed regularly, particularly as the disease progresses, to manage motor fluctuations, dyskinesias, and side effects.

b) Cognitive Monitoring:

Patients with Parkinson's disease should be monitored for cognitive decline, depression, and other non-motor symptoms.

c) Bone Health Monitoring:

Elderly patients with PD are at increased risk of falls and fractures, so regular monitoring for osteoporosis and fall prevention strategies are essential.

d) Speech and Swallowing Assessment:

Speech and language therapy should monitor patients for speech difficulties and dysphagia, especially as the disease progresses.

9. Complications of Parkinson's Disease

a) **Motor Complications:**

Long-term levodopa use can lead to motor fluctuations ("on-off" phenomena) and dyskinesias (involuntary movements).

b) **Falls and Fractures:**

Postural instability and balance problems significantly increase the risk of falls, which can lead to fractures, particularly in older patients.

c) **Cognitive Decline and Dementia:**

As Parkinson's disease progresses, many patients develop cognitive impairment or Parkinson's disease dementia, affecting memory, attention, and executive function.

d) **Depression and Anxiety:**

Mood disorders are common in PD and can significantly affect quality of life.

e) **Autonomic Dysfunction:**

Orthostatic hypotension, urinary incontinence, constipation, and erectile dysfunction are common autonomic symptoms of PD.

Summary of Key Points for Parkinson's Disease

Parkinson's disease is a progressive neurodegenerative disorder characterised by motor symptoms such as tremor, bradykinesia, and rigidity, as well as non-motor symptoms including cognitive impairment and autonomic dysfunction.

Diagnosis is based on clinical criteria (bradykinesia plus resting tremor, rigidity, or postural instability) and can be supported by imaging (DaTSCAN) if necessary.

First-line treatment includes **levodopa**, dopamine agonists, and MAO-B inhibitors, with the goal of improving motor symptoms and maintaining function.

Regular monitoring is essential to manage both motor and non-motor symptoms, with multidisciplinary care providing support for physiotherapy, speech therapy, and mental health needs.

51. Pressure Sores and Skin Ulcers

1. Detailed Definition of Pressure Sores and Skin Ulcers

Pressure sores (also known as **pressure ulcers**, **bedsores**, or **decubitus ulcers**) are areas of skin and underlying tissue damage caused by prolonged pressure or friction. These sores typically develop over bony prominences, such as the sacrum, heels, hips, and elbows, where prolonged pressure impairs blood flow, leading to tissue ischemia and necrosis. Pressure sores are classified into stages based on the depth and severity of tissue damage, ranging from Stage 1 (non-blanchable erythema of intact skin) to Stage 4 (full-thickness tissue loss with exposed bone or muscle).

Skin ulcers are broader in definition and can include ulcers caused by arterial insufficiency, venous stasis, or neuropathy. These ulcers result from poor blood flow or nerve damage and can occur anywhere on the body, commonly on the legs and feet.

2. Common Presenting Complaints and Symptoms

Patients with pressure sores or skin ulcers may present with:

a) **Reddened Skin:**

Early signs of pressure sores include areas of red, non-blanching skin, typically over bony prominences.

b) **Blisters or Open Wounds:**

As pressure sores progress, blisters or superficial skin breakdown may be visible. Full-thickness skin loss can occur in more advanced stages.

c) **Pain or Discomfort:**

Patients may report pain or discomfort at the site of the ulcer, though some, especially those with neuropathy, may not experience pain.

d) **Odour and Discharge:**

Infected ulcers may produce an offensive odour and discharge, with signs of infection such as pus, increased warmth, or redness around the wound.

e) **Necrotic Tissue:**

In advanced pressure sores, necrotic (black or brown) tissue may be visible, indicating severe tissue damage.

f) **Signs of Systemic Infection:**

Patients with infected pressure sores or skin ulcers may present with fever, chills, and signs of sepsis, including confusion and tachycardia.

3. First-Line Investigations

Assessment and diagnosis of pressure sores and skin ulcers involve both physical examination and investigations to determine underlying causes and complications:

a) **Wound Assessment:**

What it examines: Location, size, depth, exudate, odour, and signs of infection.

Purpose: Classifies the severity of the pressure sore or ulcer and identifies signs of infection or necrosis. The wound should be staged according to established guidelines (e.g., National Pressure Ulcer Advisory Panel).

b) **Full Blood Count (FBC):**

What it measures: White blood cell count, haemoglobin, and platelets.

Purpose: Detects infection, anaemia, or other haematological conditions that may complicate wound healing.

c) C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR):

What they measure: Markers of inflammation.

Purpose: Elevated levels indicate an inflammatory response, suggesting infection or a systemic inflammatory condition.

d) Wound Culture and Sensitivity:

What it examines: A sample from the ulcer is cultured to identify bacterial pathogens.

Purpose: Confirms the presence of infection and determines the most appropriate antibiotic treatment.

e) Blood Glucose and HbA1c:

What it measures: Blood glucose levels and long-term glucose control (HbA1c).

Purpose: Identifies poorly controlled diabetes, which is a risk factor for delayed wound healing and ulcer formation.

f) Ankle-Brachial Pressure Index (ABPI) (for leg ulcers):

What it examines: The ratio of the systolic blood pressure at the ankle to the systolic pressure at the arm.

Purpose: Assesses arterial blood flow to the legs, helping to differentiate between venous and arterial ulcers. A low ABPI (<0.9) suggests arterial insufficiency.

g) Doppler Ultrasound (for leg ulcers):

What it examines: Blood flow in the leg arteries and veins.

Purpose: Helps diagnose venous insufficiency or arterial disease contributing to ulcer formation.

4. Explanation of Investigations

a) Wound Culture and Sensitivity:

A wound culture is essential for identifying bacterial infections, particularly in ulcers that are not healing or have signs of infection. The results guide antibiotic selection, ensuring that treatment targets the specific pathogens present in the wound.

b) Ankle-Brachial Pressure Index (ABPI):

This test is particularly important in leg ulcers to differentiate between venous and arterial ulcers. An ABPI of <0.9 suggests arterial disease, while a value >1.3 indicates calcified, non-compressible arteries, often seen in patients with diabetes.

5. Diagnostic Criteria for Pressure Sores and Skin Ulcers

Pressure sores are classified into four stages based on the severity of tissue damage:

Stage 1: Non-blanchable erythema of intact skin.

Stage 2: Partial-thickness skin loss with exposed dermis (may appear as a blister or shallow ulcer).

Stage 3: Full-thickness skin loss with visible fat but no bone, tendon, or muscle exposure.

Stage 4: Full-thickness tissue loss with exposed bone, tendon, or muscle. Necrotic tissue may be present.

Venous ulcers: Typically located on the medial malleolus, with a shallow, irregular shape and associated oedema or varicose veins. ABPI is usually >0.9 .

Arterial ulcers: Often located on the toes or lateral ankle, with a well-defined border, pale or necrotic base, and minimal exudate. ABPI is typically <0.9 .

6. First-Line Therapy According to Guidelines

Management of pressure sores and skin ulcers involves a combination of local wound care, infection control, and addressing the underlying causes of pressure or poor blood flow.

a) Wound Care and Pressure Offloading:

Wound Dressing:

Action: Select appropriate dressings (e.g., hydrocolloid, foam, alginate) based on the ulcer's depth, exudate level, and presence of infection.

Outcome: Promotes wound healing by maintaining a moist environment, absorbing exudate, and protecting the wound from infection.

Pressure Redistribution:

Action: Use specialised mattresses, cushions, or offloading devices to reduce pressure on bony prominences.

Outcome: Prevents further tissue damage by redistributing pressure away from high-risk areas.

b) Debridement of Necrotic Tissue:

Action: Remove necrotic tissue using sharp, enzymatic, or autolytic debridement techniques.

Outcome: Removes dead tissue, which can harbour bacteria, and facilitates healing by exposing healthy tissue.

c) Antibiotic Therapy:

Action: Systemic antibiotics are indicated for infected ulcers (e.g., cellulitis, osteomyelitis) and should be guided by culture results.

Outcome: Treats infection, reduces inflammation, and prevents systemic spread (e.g., sepsis).

d) Optimising Nutrition:

Action: Ensure adequate protein, vitamin C, and zinc intake to promote wound healing.

Outcome: Supports tissue repair and immune function, especially in malnourished or frail elderly patients.

e) **Managing Comorbidities:**

Diabetes Control:

Action: Optimise blood glucose levels to improve wound healing.

Outcome: Prevents complications such as delayed healing and further ulceration in diabetic patients.

Vascular Surgery Referral:

Action: In cases of arterial ulcers, refer for surgical revascularisation or angioplasty if poor blood flow is a contributing factor.

Outcome: Improves blood supply to the affected area, promoting healing and preventing further ulcers.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Aggressive Debridement in Ischaemic Ulcers: Sharp debridement should be avoided in arterial ulcers without adequate blood flow, as it can worsen tissue damage.

b) **Second-Line Therapy:**

Negative Pressure Wound Therapy (NPWT):

Indication: For large, deep ulcers with significant exudate that are not responding to conventional dressings.

Mechanism: Applies suction to the wound, removing exudate and promoting granulation tissue formation.

Outcome: Accelerates wound healing in chronic or deep ulcers.

Hyperbaric Oxygen Therapy (HBOT):

Indication: For non-healing ulcers, particularly in diabetic foot ulcers or ulcers complicated by ischaemia.

Mechanism: Increases oxygen delivery to the wound site, enhancing tissue repair and reducing infection.

Outcome: May improve healing rates in selected patients with refractory ulcers.

8. Routine Monitoring and Follow-Up

a) **Regular Wound Assessment:**

Monitor the wound size, depth, exudate, and signs of infection at each dressing change to assess healing progress and adjust treatment as needed.

b) Nutritional Monitoring:

Regularly assess nutritional status, particularly in frail or malnourished patients, and provide supplementation as necessary.

c) Infection Monitoring:

Monitor for signs of infection (e.g., increased pain, warmth, redness) and perform wound cultures if infection is suspected.

d) Pressure Relief:

Ensure continued use of pressure-relieving devices and reposition the patient regularly to prevent new pressure sores from forming.

9. Complications of Pressure Sores and Skin Ulcers

a) Infection:

Pressure sores and skin ulcers can become infected, leading to cellulitis, osteomyelitis (infection of the bone), or sepsis, particularly in immunocompromised or frail patients.

b) Chronic Non-Healing Ulcers:

Ulcers that do not heal despite treatment may result in long-term disability, pain, and a higher risk of secondary infection.

c) Osteomyelitis:

Pressure sores, particularly those over bony prominences, can extend into the underlying bone, causing infection. This requires prolonged antibiotic therapy and sometimes surgical intervention.

d) Sepsis:

Infected ulcers can lead to sepsis, a life-threatening systemic infection that requires urgent treatment with intravenous antibiotics and supportive care.

Summary of Key Points for Pressure Sores and Skin Ulcers

Pressure sores and skin ulcers result from prolonged pressure, poor circulation, or nerve damage, often occurring in elderly or immobile patients.

Diagnosis involves staging the severity of the pressure sore and performing investigations such as wound cultures, blood tests, and ABPI to identify infection and underlying causes.

First-line treatment includes wound care, pressure redistribution, infection control, and addressing underlying conditions such as diabetes or vascular disease.

Regular monitoring and follow-up are crucial to ensure wound healing, prevent complications, and reduce the risk of further ulceration.

52. Sensory Impairment: Hearing Loss and Visual Loss

1. Detailed Definition of Sensory Impairment (Hearing Loss and Visual Loss)

Sensory impairment in the elderly refers to the partial or complete loss of hearing and/or vision, which can significantly affect quality of life, communication, and independence. Hearing and visual impairments are common in older adults and can result from age-related changes, chronic conditions, or acute injuries.

Hearing Loss: A reduction in the ability to perceive sound, ranging from mild difficulty in understanding speech to profound deafness. Hearing loss in the elderly is most often due to **presbycusis** (age-related hearing loss), a progressive sensorineural hearing loss that affects high-frequency sounds. Conductive hearing loss, caused by issues such as earwax impaction or middle ear problems, is also common in this population.

Visual Loss: A reduction in the ability to see clearly, often due to age-related eye diseases such as **cataracts**, **glaucoma**, **age-related macular degeneration (AMD)**, and **diabetic retinopathy**. Visual impairment can range from mild blurring to complete blindness.

Both types of sensory impairment can lead to difficulties with communication, social isolation, and an increased risk of falls and injury.

2. Common Presenting Complaints and Symptoms

Hearing Loss:

Difficulty Hearing Conversations:

Difficulty understanding speech, especially in noisy environments, or when multiple people are speaking.

Increased Volume on Devices:

The need to increase the volume on the television, radio, or phone.

Tinnitus:

A ringing, buzzing, or hissing sound in the ears, often accompanying hearing loss.

Social Withdrawal:

Reduced participation in social activities due to difficulty hearing and understanding speech.

Asking for Repetition:

Frequently asking others to repeat what they've said or misunderstanding conversations.

Visual Loss:

Blurred Vision:

Difficulty focusing, especially on near or far objects. May present with double vision or halos around lights in cataracts.

Difficulty Reading:

Challenges reading small print, even with corrective lenses, and difficulty recognising faces.

Glare Sensitivity:

Increased sensitivity to bright lights or glare, often associated with cataracts or AMD.

Reduced Peripheral Vision:

Loss of side vision (common in glaucoma), making it difficult to navigate safely.

Frequent Falls or Bumping into Objects:

Difficulty navigating familiar spaces, leading to falls or accidents.

Night Blindness:

Difficulty seeing in low-light conditions, often associated with conditions like cataracts or retinitis pigmentosa.

3. First-Line Investigations

Diagnosis of hearing and visual impairments involves clinical assessment and specific diagnostic tests to determine the type and extent of the sensory loss.

Hearing Loss:**a) Otoscopy:**

What it examines: The ear canal and eardrum.

Purpose: Identifies visible causes of conductive hearing loss, such as earwax impaction, middle ear effusion, or perforation of the tympanic membrane.

b) Pure Tone Audiometry (PTA):

What it measures: The ability to hear different tones across a range of frequencies.

Purpose: Quantifies the degree and type (sensorineural, conductive, or mixed) of hearing loss.

c) Tympanometry:

What it examines: Measures middle ear pressure and mobility of the tympanic membrane.

Purpose: Detects middle ear pathology, such as otitis media or Eustachian tube dysfunction, which can cause conductive hearing loss.

d) Speech Audiometry:

What it measures: Ability to understand speech at different volumes.

Purpose: Assesses how hearing loss affects communication, which helps guide hearing aid fitting.

Visual Loss:**a) Visual Acuity Testing (Snellen Chart):**

What it examines: Measures the clarity of vision (distance vision).

Purpose: Assesses overall visual sharpness and identifies reduced visual acuity.

b) Slit-Lamp Examination:

What it examines: The structures of the eye, including the cornea, lens, and retina.

Purpose: Detects conditions such as cataracts, corneal abrasions, and macular degeneration.

c) Intraocular Pressure Measurement (Tonometry):

What it examines: Measures the pressure inside the eye.

Purpose: Elevated intraocular pressure suggests glaucoma, a major cause of visual loss in older adults.

d) Visual Field Testing:

What it examines: Assesses the full horizontal and vertical range of peripheral vision.

Purpose: Detects peripheral vision loss, commonly associated with glaucoma.

e) Fundoscopy:

What it examines: Direct examination of the retina and optic nerve.

Purpose: Identifies signs of diabetic retinopathy, macular degeneration, or optic neuropathy.

4. Explanation of Investigations

a) Pure Tone Audiometry (PTA):

PTA is the standard test used to diagnose hearing loss. It measures the threshold at which different frequencies of sound can be heard. A sensorineural hearing loss (common in presbycusis) shows reduced hearing across all frequencies, while conductive hearing loss shows a gap between air and bone conduction.

b) Slit-Lamp Examination:

A slit-lamp allows the eye doctor to examine the front and back of the eye under high magnification, helping to diagnose cataracts, macular degeneration, and other structural problems.

5. Diagnostic Criteria for Hearing Loss and Visual Loss

Hearing Loss:

Conductive Hearing Loss: Blockage or damage to the outer or middle ear prevents sound from being conducted properly. Causes include earwax, otitis media, or otosclerosis.

Sensorineural Hearing Loss: Damage to the inner ear (cochlea) or the auditory nerve causes hearing loss. Presbycusis is the most common form, affecting high frequencies first.

Mixed Hearing Loss: A combination of conductive and sensorineural components.

Visual Loss:

Cataracts: Clouding of the lens, leading to blurred vision, glare sensitivity, and difficulty seeing at night.

Glaucoma: Damage to the optic nerve, often due to increased intraocular pressure, leading to peripheral vision loss.

Age-Related Macular Degeneration (AMD): Damage to the macula (central part of the retina), leading to central vision loss and difficulty reading or recognising faces.

Diabetic Retinopathy: Retinal damage caused by poorly controlled diabetes, leading to vision loss, floaters, and eventually blindness.

6. First-Line Therapy According to Guidelines

Management of hearing and visual loss in elderly patients focuses on improving function, preventing further deterioration, and enhancing quality of life.

Hearing Loss:

a) Hearing Aids:

Action: Devices amplify sound to improve hearing.

Outcome: Improves communication and quality of life in patients with mild to moderate sensorineural hearing loss.

b) Earwax Removal:

Action: Earwax impaction can be treated with softening drops or manual removal by a healthcare professional.

Outcome: Restores hearing in cases of conductive hearing loss caused by wax blockage.

c) Cochlear Implants:

Action: Surgical implantation of a device that stimulates the auditory nerve directly.

Outcome: Used for patients with severe to profound sensorineural hearing loss who do not benefit from hearing aids.

d) Assistive Listening Devices:

Action: Devices like amplified phones or TV listeners.

Outcome: Enhances hearing in specific situations where hearing aids may not be effective.

Visual Loss:

a) Cataract Surgery:

Action: Removal of the cloudy lens and replacement with an artificial intraocular lens.

Outcome: Restores vision in patients with cataracts and improves quality of life.

b) Glaucoma Treatment:

Topical Eye Drops (e.g., prostaglandin analogs, beta-blockers):

Action: Reduces intraocular pressure to prevent further optic nerve damage.

Outcome: Slows the progression of glaucoma and prevents vision loss.

Surgery (e.g., trabeculectomy):

Action: Creates a new drainage pathway for fluid to leave the eye, reducing intraocular pressure.

Outcome: Reduces the risk of further optic nerve damage in advanced cases of glaucoma.

c) **Anti-VEGF Injections** (for wet AMD):

Action: Injections into the eye that inhibit the growth of abnormal blood vessels in the retina.

Outcome: Slows vision loss and, in some cases, improves vision in patients with wet macular degeneration.

d) **Laser Photocoagulation** (for diabetic retinopathy):

Action: Laser therapy to seal leaking blood vessels in the retina.

Outcome: Prevents further retinal damage and vision loss in diabetic retinopathy.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Cochlear Implants: May not be suitable for patients with significant cognitive decline or anatomical abnormalities of the cochlea.

Cataract Surgery: May be contraindicated in patients with severe eye infections or other ocular conditions that increase the risk of surgery.

b) **Second-Line Therapy:**

Bone-Anchored Hearing Aids (BAHA):

Indication: For patients with conductive hearing loss or mixed hearing loss who cannot use conventional hearing aids.

Mechanism: Surgically implanted device that transmits sound through bone conduction.

Outcome: Improves hearing in patients with conditions such as chronic ear infections or malformations of the ear.

Glaucoma Surgery (e.g., shunt implant):

Indication: For patients with refractory glaucoma where other treatments have failed.

Mechanism: Shunt surgery helps drain fluid from the eye to control intraocular pressure.

Outcome: Prevents further vision loss in advanced glaucoma.

8. Routine Monitoring and Follow-Up

a) **Hearing Aid Follow-Up:**

Patients using hearing aids should have regular follow-up appointments to check the device's function and fit, and to adjust settings as needed.

b) **Visual Acuity Monitoring:**

Patients with conditions such as glaucoma or AMD should have regular eye examinations to monitor disease progression and adjust treatment accordingly.

c) **Intraocular Pressure Checks:**

Patients with glaucoma should have regular checks of their intraocular pressure to ensure that it remains within target ranges.

9. Complications of Sensory Impairment

a) **Falls and Injuries:**

Both hearing and visual impairments increase the risk of falls, which can lead to fractures and other injuries, particularly in older adults.

b) **Social Isolation:**

Hearing and visual impairments can lead to communication difficulties, withdrawal from social activities, and increased isolation, contributing to depression and cognitive decline.

c) **Cognitive Decline:**

There is a strong association between hearing loss and an increased risk of dementia, as sensory impairment can reduce cognitive stimulation and social engagement.

Summary of Key Points for Sensory Impairment (Hearing and Visual Loss)

Hearing and visual impairments are common in older adults and can have a significant impact on communication, independence, and quality of life.

Diagnosis involves a combination of clinical assessments, such as pure tone audiometry for hearing loss and slit-lamp examination or visual field testing for visual loss.

First-line treatment includes hearing aids, cataract surgery, glaucoma eye drops, and other interventions depending on the cause of the impairment.

Regular monitoring and follow-up are essential to adjust treatment, prevent further sensory loss, and reduce the risk of complications such as falls and social isolation.

53. Stroke

1. Detailed Definition of Stroke

A **stroke** is a medical emergency characterised by a sudden loss of brain function due to the disruption of blood flow to the brain. This disruption can be caused by:

Ischaemic Stroke: The most common type, accounting for approximately 85% of strokes, results from a blockage (thrombus or embolus) in a cerebral artery, cutting off the blood supply to part of the brain.

Haemorrhagic Stroke: Results from the rupture of a blood vessel, leading to bleeding within the brain (intracerebral haemorrhage) or around the brain (subarachnoid haemorrhage).

Transient Ischaemic Attack (TIA): Often called a “mini-stroke,” it occurs when the blood flow to the brain is temporarily blocked but resolves within 24 hours without lasting damage.

Stroke can lead to permanent neurological damage, disability, or death, depending on the location and extent of the brain injury.

2. Common Presenting Complaints and Symptoms

The symptoms of stroke vary depending on the area of the brain affected but typically include:

a) Sudden Weakness or Paralysis:

Usually affects one side of the body (hemiparesis or hemiplegia), including the face, arm, and leg.

b) Sudden Numbness or Loss of Sensation:

Often one-sided (hemisensory loss), affecting the face, arm, or leg.

c) Difficulty Speaking (Aphasia):

Expressive aphasia (difficulty producing speech) or receptive aphasia (difficulty understanding speech).

d) Sudden Visual Disturbances:

Loss of vision in one or both eyes (e.g., visual field deficits), or double vision (diplopia).

e) Sudden Dizziness or Loss of Balance:

Difficulty walking, unsteadiness, or vertigo.

f) Severe Headache (in haemorrhagic stroke):

Sudden, severe headache described as "the worst headache ever."

g) Confusion or Altered Consciousness:

Difficulty understanding or confusion, often seen in more severe strokes.

3. First-Line Investigations

Rapid and accurate diagnosis of stroke is essential to initiate appropriate treatment and improve outcomes. Investigations include imaging and laboratory tests:

a) Non-Contrast CT Brain Scan:

What it examines: Imaging of the brain to distinguish between ischaemic and haemorrhagic stroke.

Purpose: CT is used to rapidly identify haemorrhage, infarction, or other causes of neurological symptoms. It helps guide treatment decisions, particularly for thrombolysis.

b) MRI Brain:

What it examines: Detailed imaging of brain tissue, using diffusion-weighted imaging (DWI) to detect ischaemic areas.

Purpose: MRI is more sensitive than CT in detecting small or early infarcts and is particularly useful in diagnosing posterior circulation strokes or TIAs.

c) Carotid Doppler Ultrasound:

What it examines: Blood flow in the carotid arteries.

Purpose: Detects carotid artery stenosis (narrowing), which may be a source of emboli causing ischaemic stroke.

d) ECG (Electrocardiogram):

What it examines: Heart rhythm and electrical activity.

Purpose: Identifies atrial fibrillation, a common cause of embolic stroke.

e) Blood Tests:

What they measure: Full blood count (FBC), electrolytes, glucose, coagulation profile, and lipid profile.

Purpose: Identifies underlying conditions (e.g., hyperglycaemia, thrombocytopenia, electrolyte imbalances) that may contribute to stroke or impact treatment.

f) Echocardiogram:

What it examines: Structure and function of the heart.

Purpose: Detects sources of emboli (e.g., left ventricular thrombus or atrial thrombus) that could cause ischaemic stroke.

g) CT or MR Angiography:

What it examines: Visualises the blood vessels in the brain and neck.

Purpose: Identifies stenosis, occlusions, or aneurysms that may contribute to stroke.

4. Explanation of Investigations

a) Non-Contrast CT Brain Scan:

This is the first-line investigation in suspected stroke because it rapidly distinguishes between ischaemic and haemorrhagic stroke. It is especially useful in identifying intracerebral haemorrhage, which requires different management from ischaemic stroke.

b) Carotid Doppler Ultrasound:

Carotid Doppler ultrasound evaluates the degree of stenosis in the carotid arteries, which supply blood to the brain. Carotid stenosis is a major risk factor for ischaemic stroke, and significant narrowing may require surgical intervention.

5. Diagnostic Criteria for Stroke

Diagnosis of stroke is based on the sudden onset of focal neurological symptoms lasting more than 24 hours, confirmed by neuroimaging. Diagnostic criteria include:

Sudden Onset of Neurological Deficits: Symptoms such as hemiparesis, aphasia, or visual disturbances, lasting more than 24 hours.

Neuroimaging Evidence: CT or MRI shows evidence of brain infarction or haemorrhage.

Exclusion of Other Causes: Symptoms are not attributable to other conditions such as a brain tumour, seizure, or migraine.

For **Transient Ischaemic Attack (TIA)**, symptoms are similar but resolve within 24 hours, and neuroimaging does not show infarction.

NICE guidelines recommend immediate brain imaging in suspected stroke to guide treatment decisions, particularly if thrombolysis is being considered.

6. First-Line Therapy According to Guidelines

Management of stroke depends on the type of stroke (ischaemic or haemorrhagic) and focuses on restoring blood flow in ischaemic stroke and controlling bleeding in haemorrhagic stroke.

Ischaemic Stroke:

a) Thrombolysis with Alteplase:

Action: Tissue plasminogen activator (tPA) dissolves the clot that is blocking blood flow to the brain.

Dose: Alteplase 0.9 mg/kg IV, with 10% given as a bolus and the remainder over 60 minutes.

Outcome: Significantly improves outcomes if given within 4.5 hours of symptom onset in eligible patients. Contraindicated in haemorrhagic stroke.

b) Thrombectomy:

Action: Mechanical removal of the clot in patients with large vessel occlusion.

Outcome: Reduces disability in patients with large ischaemic strokes, particularly if performed within 6 hours of symptom onset.

c) Antiplatelet Therapy:

Aspirin:

Action: Prevents further clot formation by inhibiting platelet aggregation.

Dose: 300 mg orally or rectally once daily, usually started 24 hours after thrombolysis or immediately in patients not receiving thrombolysis.

Outcome: Reduces the risk of recurrent stroke.

Clopidogrel (long-term):

Action: Antiplatelet agent used to prevent recurrent stroke.

Dose: 75 mg orally once daily.

d) Statins:

Action: Lowers cholesterol and stabilises atherosclerotic plaques.

Dose: Atorvastatin 80 mg orally once daily.

Outcome: Reduces the risk of future cardiovascular events in patients with ischaemic stroke.

e) Blood Pressure Control:

Action: Antihypertensive medications (e.g., ACE inhibitors, calcium channel blockers) help manage high blood pressure.

Outcome: Reduces the risk of recurrent stroke by controlling a major risk factor.

Haemorrhagic Stroke:

a) Blood Pressure Control:

Action: Aggressive blood pressure management using agents such as labetalol or nicardipine to lower systolic blood pressure to <140 mmHg.

Outcome: Reduces the risk of further bleeding and improves outcomes.

b) Surgical Intervention:

Action: In cases of large haemorrhages, surgical evacuation of the haematoma may be required.

Outcome: Reduces intracranial pressure and prevents further neurological deterioration.

c) Reversal of Anticoagulation (if applicable):

Action: For patients on anticoagulants (e.g., warfarin), reversal agents (e.g., vitamin K, prothrombin complex concentrate) are used to restore normal clotting.

Outcome: Reduces ongoing bleeding.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Thrombolysis: Contraindicated in patients with recent major surgery, active bleeding, a history of intracerebral haemorrhage, or severe hypertension (>185/110 mmHg).

b) Second-Line Therapy:

Endovascular Thrombectomy:

Indication: For patients with large vessel occlusion who are not eligible for thrombolysis or who present outside the thrombolysis window.

Outcome: Mechanical clot removal improves outcomes in patients with large ischaemic strokes.

Carotid Endarterectomy:

Indication: For patients with significant carotid artery stenosis (70-99%) following an ischaemic stroke or TIA.

Outcome: Reduces the risk of recurrent stroke by removing the atherosclerotic plaque causing stenosis.

8. Routine Monitoring and Follow-Up

a) Neurological Monitoring:

Frequent monitoring of neurological status is essential, particularly in the first 48-72 hours after a stroke. Watch for signs of deterioration, such as worsening consciousness, motor deficits, or increasing headaches.

b) Blood Pressure Monitoring:

Blood pressure should be closely monitored and controlled to prevent recurrent strokes or haemorrhage.

c) Rehabilitation Assessment:

Patients should be referred for physiotherapy, occupational therapy, and speech therapy as soon as possible to assess and address disabilities.

d) Long-Term Risk Factor Management:

Control of risk factors such as hypertension, hyperlipidaemia, and diabetes is crucial in preventing recurrent strokes.

9. Complications of Stroke

a) Permanent Neurological Deficits:

Stroke can lead to long-term disabilities, including hemiplegia, aphasia, cognitive impairment, and difficulty swallowing (dysphagia).

b) Recurrent Stroke:

Patients who have had a stroke are at high risk of subsequent strokes, particularly if underlying risk factors (e.g., atrial fibrillation, hypertension) are not well controlled.

c) Deep Vein Thrombosis (DVT) and Pulmonary Embolism (PE):

Immobility following a stroke increases the risk of DVT and PE, particularly in patients with limb paralysis.

d) **Depression:**

Post-stroke depression is common and may affect the patient's ability to participate in rehabilitation and recovery.

e) **Aspiration Pneumonia:**

Dysphagia (difficulty swallowing) can lead to aspiration of food or liquids into the lungs, increasing the risk of pneumonia.

Summary of Key Points for Stroke

Stroke is a medical emergency caused by the interruption of blood flow to the brain (ischaemic or haemorrhagic), leading to neurological deficits.

Immediate imaging with **non-contrast CT** is essential to differentiate between ischaemic and haemorrhagic stroke.

Thrombolysis with alteplase is the mainstay of treatment for ischaemic stroke if given within 4.5 hours of symptom onset, and **mechanical thrombectomy** is effective for large vessel occlusions.

Haemorrhagic stroke management focuses on **blood pressure control** and, in some cases, surgical intervention.

Regular follow-up and rehabilitation are crucial to improving recovery and preventing complications such as recurrent stroke and disability.

54. Surgical Liaison

1. Detailed Definition of Surgical Liaison in Elderly Care

Surgical liaison in the care of the elderly refers to the collaborative management of older patients undergoing surgery, ensuring that their unique medical, functional, and social needs are addressed. Elderly patients often have multiple comorbidities, frailty, and age-related physiological changes that increase their risk of complications during and after surgery. The aim of surgical liaison is to provide comprehensive, multidisciplinary care by involving geriatricians early in the surgical pathway to optimise preoperative, perioperative, and postoperative outcomes.

Surgical liaison teams may include geriatricians, anaesthetists, surgeons, physiotherapists, occupational therapists, nurses, and social workers. Their role is to assess frailty, manage comorbidities, optimise medications, plan for rehabilitation, and provide ongoing care to reduce complications such as delirium, infections, and prolonged immobility.

2. Common Presenting Complaints and Issues

Elderly patients requiring surgical care often present with a range of medical and functional concerns, such as:

a) **Multimorbidity:**

Elderly patients typically have multiple chronic conditions (e.g., heart failure, diabetes, chronic obstructive pulmonary disease), which complicate surgical planning and increase the risk of perioperative complications.

b) Frailty:

Frailty increases vulnerability to stressors, such as surgery, leading to higher rates of complications and delayed recovery.

c) Functional Decline:

Preoperative functional limitations, such as reduced mobility or difficulty performing activities of daily living (ADLs), may worsen after surgery without appropriate rehabilitation.

d) Cognitive Impairment and Delirium:

Elderly patients, particularly those with dementia or mild cognitive impairment, are at higher risk of postoperative delirium, which can lead to prolonged hospital stays and functional decline.

e) Polypharmacy:

Older patients often take multiple medications, which may increase the risk of drug interactions, adverse effects, and surgical complications such as falls, bleeding, or hypotension.

f) Nutritional Deficiency:

Malnutrition is common in elderly patients and is associated with poorer surgical outcomes, delayed wound healing, and increased risk of infection.

g) Social Circumstances:

Issues such as inadequate social support or the need for long-term care planning must be addressed before and after surgery.

3. First-Line Assessments and Investigations

Assessment of elderly patients undergoing surgery involves a comprehensive evaluation to identify potential risks and optimise their health prior to surgery. Key assessments include:

a) Comprehensive Geriatric Assessment (CGA):

What it examines: A holistic evaluation of the patient's medical, functional, cognitive, and social needs.

Purpose: Identifies frailty, comorbidities, and potential risks, enabling a tailored approach to perioperative care.

b) Frailty Assessment (e.g., Clinical Frailty Scale):

What it examines: Assesses the degree of frailty, including weakness, weight loss, and reduced physical activity.

Purpose: Identifies patients at increased risk of poor surgical outcomes and helps guide decision-making.

c) Cognitive Screening (e.g., MMSE or MoCA):

What it measures: Cognitive function, including memory, attention, and orientation.

Purpose: Detects cognitive impairment and identifies patients at risk of postoperative delirium.

d) Nutritional Assessment (e.g., MUST):

What it examines: Assesses nutritional status and risk of malnutrition.

Purpose: Ensures nutritional support is optimised before and after surgery, reducing the risk of complications.

e) Medication Review:

What it examines: A comprehensive review of all prescribed and over-the-counter medications.

Purpose: Identifies high-risk medications (e.g., anticoagulants, antiplatelets, antihypertensives) that may need to be adjusted or discontinued perioperatively.

f) Preoperative Blood Tests:

What they measure: Full blood count (FBC), renal function (U&Es), liver function, coagulation profile, and blood glucose.

Purpose: Identifies anaemia, electrolyte imbalances, and other abnormalities that may affect surgical risk and recovery.

g) Echocardiogram and ECG:

What it examines: Heart function and electrical activity.

Purpose: Assesses cardiac risk, particularly in patients with known or suspected cardiovascular disease.

h) Pulmonary Function Tests (if needed):

What it examines: Measures lung function, especially in patients with chronic lung disease.

Purpose: Assesses the risk of respiratory complications post-surgery.

4. Explanation of Assessments

a) Comprehensive Geriatric Assessment (CGA):

The CGA is a multidimensional assessment conducted by a multidisciplinary team to evaluate the overall health and functional status of elderly patients. It is essential for identifying risks such as frailty, cognitive impairment, and social factors that may affect surgical outcomes and planning appropriate interventions.

b) Frailty Assessment:

Frailty is a key predictor of postoperative complications and mortality. Tools such as the Clinical

Frailty Scale (CFS) provide a quick and accurate measure of frailty, helping guide preoperative counselling and decision-making.

5. Preoperative and Perioperative Management in Surgical Liaison

Management involves optimising the patient's medical status before surgery and ensuring close monitoring during the perioperative period. Interventions may include:

a) Optimisation of Comorbidities:

Action: Stabilise chronic conditions (e.g., control blood pressure, optimise diabetes management, manage heart failure).

Outcome: Reduces the risk of perioperative complications such as heart failure, arrhythmias, or metabolic imbalances.

b) Frailty Intervention:

Action: Preoperative physiotherapy or "prehabilitation" to improve physical function, and nutritional support to address malnutrition.

Outcome: Enhances physical resilience, reduces the risk of postoperative functional decline, and improves recovery.

c) Cognitive Care:

Action: Monitor for early signs of delirium and provide perioperative measures (e.g., maintaining sleep hygiene, minimising unnecessary medications, promoting early mobilisation).

Outcome: Reduces the incidence and severity of postoperative delirium, improving cognitive outcomes and reducing hospital stays.

d) Medication Management:

Action: Adjust or discontinue medications that may increase surgical risk (e.g., anticoagulants, antiplatelets, antihypertensives).

Outcome: Reduces the risk of bleeding, hypotension, or other medication-related complications.

e) Prophylaxis:

Venous Thromboembolism (VTE) Prophylaxis:

Action: Use of low-molecular-weight heparin (LMWH) or mechanical prophylaxis to reduce the risk of deep vein thrombosis (DVT).

Outcome: Prevents postoperative thromboembolic events.

Antibiotic Prophylaxis:

Action: Administer prophylactic antibiotics to prevent surgical site infections.

Outcome: Reduces the risk of postoperative infections.

6. Postoperative Care and Rehabilitation

Postoperative care in elderly patients focuses on minimising complications and promoting recovery through a multidisciplinary approach:

a) Early Mobilisation:

Action: Initiate physiotherapy as soon as possible to promote mobility and reduce the risk of complications such as pressure sores, DVT, and pneumonia.

Outcome: Enhances recovery, improves functional outcomes, and reduces the length of hospital stay.

b) Delirium Prevention and Management:

Action: Provide a calm environment, ensure adequate pain control, avoid unnecessary sedatives, and encourage regular orientation (e.g., ensuring patients wear glasses and hearing aids).

Outcome: Reduces the incidence of delirium, which is common in elderly surgical patients and associated with poor outcomes.

c) Multidisciplinary Rehabilitation:

Action: Involvement of occupational therapists, physiotherapists, and social workers to support activities of daily living (ADLs), arrange home adaptations, and plan for safe discharge.

Outcome: Facilitates early discharge, reduces the risk of readmission, and improves the patient's independence and quality of life.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery in High-Risk Frail Patients: Surgery may be contraindicated in patients with severe frailty, significant comorbidities, or poor functional reserve, where the risks outweigh the benefits.

b) Second-Line Therapy:

Conservative Management:

Indication: For patients deemed unsuitable for surgery due to frailty or high surgical risk.

Action: Non-surgical options, such as physiotherapy, pain management, and optimised medical care.

Outcome: Provides symptom relief and improves quality of life without the risks of surgery.

8. Routine Monitoring and Follow-Up

a) Postoperative Monitoring:

Close monitoring of vital signs, cognitive function, and mobility during the first 48-72 hours post-surgery is critical to detect complications early.

b) Nutritional Follow-Up:

Regular assessment of nutritional status is necessary, especially in patients at risk of malnutrition, to ensure adequate calorie and protein intake for healing.

c) Multidisciplinary Team (MDT) Review:

Regular MDT meetings should take place to assess the patient's recovery and update their care plan, focusing on rehabilitation, discharge planning, and long-term support.

9. Complications in Elderly Surgical Patients

a) Delirium:

Postoperative delirium is common in elderly patients and can lead to prolonged hospitalisation, increased mortality, and long-term cognitive decline.

b) Postoperative Infections:

Elderly patients are at increased risk of infections, such as pneumonia, urinary tract infections, or surgical site infections, due to immune system changes and comorbidities.

c) Functional Decline:

Surgery may lead to a permanent reduction in mobility and independence, particularly in frail elderly patients, requiring long-term care or rehabilitation.

d) Venous Thromboembolism (VTE):

Immobility after surgery increases the risk of DVT and pulmonary embolism, particularly in patients with limited mobility or previous thromboembolic events.

Summary of Key Points for Surgical Liaison in Elderly Care

Surgical liaison involves the multidisciplinary management of elderly patients undergoing surgery, focusing on optimising preoperative health and addressing the unique needs of this population.

Key assessments include a **Comprehensive Geriatric Assessment (CGA)**, **frailty assessment**, and medication review, which guide perioperative care and reduce the risk of complications.

Preoperative and postoperative care should aim to minimise risks such as delirium, infections, and functional decline, while promoting early mobilisation and rehabilitation.

Ongoing monitoring and follow-up are essential to ensure recovery and prevent long-term complications.

55. Urinary Incontinence

1. Detailed Definition of Urinary Incontinence

Urinary incontinence (UI) is the involuntary leakage of urine, leading to social, psychological, and hygienic issues, especially common in the elderly. There are several types of urinary incontinence, each with distinct underlying causes:

Stress Incontinence: Involuntary leakage of urine during activities that increase intra-abdominal pressure, such as coughing, sneezing, or physical exertion. This is often due to weakened pelvic floor muscles or a hypermobile urethra.

Urge Incontinence: A sudden, intense urge to urinate followed by an involuntary loss of urine. It is often associated with **overactive bladder syndrome (OAB)**, where the bladder muscles contract inappropriately.

Overflow Incontinence: Occurs when the bladder does not empty fully, leading to frequent dribbling of urine. This is often due to bladder outlet obstruction or weak bladder muscles.

Functional Incontinence: Urinary leakage due to physical or cognitive impairments that prevent timely access to the toilet, despite normal bladder function (e.g., in dementia or mobility impairment).

Mixed Incontinence refers to the presence of both stress and urge incontinence symptoms.

2. Common Presenting Complaints and Symptoms

Patients with urinary incontinence may present with various symptoms depending on the type of incontinence:

a) **Stress Incontinence:**

Leakage of urine during physical activities such as coughing, laughing, sneezing, or exercise.

b) **Urge Incontinence:**

Sudden, overwhelming need to urinate with little warning, followed by involuntary leakage.

Increased frequency of urination, often more than eight times a day, and nocturia (night-time urination).

c) **Overflow Incontinence:**

Continuous dribbling of urine, often accompanied by a sensation of incomplete bladder emptying or difficulty starting urination.

d) **Functional Incontinence:**

Inability to reach the toilet in time due to physical limitations (e.g., arthritis, stroke) or cognitive issues (e.g., dementia).

e) **Mixed Incontinence:**

A combination of symptoms from both stress and urge incontinence.

3. First-Line Investigations

Evaluation of urinary incontinence involves a thorough history, physical examination, and specific investigations to identify the type of incontinence and any underlying causes:

a) **Bladder Diary:**

What it examines: Patient records the frequency, volume of urination, episodes of incontinence, and any triggers (e.g., physical activity or urgency).

Purpose: Helps differentiate between types of incontinence and assess the severity of the condition.

b) Urinalysis:

What it examines: Tests for signs of infection, blood, or glucose in the urine.

Purpose: Rules out urinary tract infection (UTI), haematuria, or diabetes as potential contributors to incontinence.

c) Post-Void Residual (PVR) Measurement:

What it examines: Measures the amount of urine left in the bladder after urination, using a bladder scanner or catheterisation.

Purpose: Identifies urinary retention or incomplete bladder emptying, which is characteristic of overflow incontinence.

d) Urodynamic Testing (if indicated):

What it examines: Measures bladder pressure, urine flow, and bladder volume during filling and voiding.

Purpose: Provides detailed information about bladder function, useful in diagnosing overactive bladder, stress incontinence, or mixed incontinence.

e) Pelvic Exam (in women):

What it examines: Assesses the strength of pelvic floor muscles, detects signs of prolapse, and checks for any masses.

Purpose: Identifies physical factors contributing to stress incontinence, such as pelvic organ prolapse.

f) Prostate Examination (in men):

What it examines: Digital rectal exam (DRE) to assess the size and texture of the prostate.

Purpose: Detects benign prostatic hyperplasia (BPH) or prostate cancer, which may cause overflow incontinence.

4. Explanation of Investigations

a) Bladder Diary:

A bladder diary is a simple, non-invasive tool that helps track urination patterns and incontinence episodes over a few days. It provides useful insight into the frequency of urination, triggers for leakage, and the severity of the condition.

b) Post-Void Residual (PVR) Measurement:

PVR testing helps identify incomplete bladder emptying, which is common in overflow incontinence. A PVR volume of >100 mL suggests incomplete emptying, which may be due to bladder outlet obstruction or detrusor muscle weakness.

5. Diagnostic Criteria for Urinary Incontinence

The diagnosis of urinary incontinence is based on patient history, clinical examination, and specific investigations that help identify the type of incontinence. Key diagnostic features include:

Stress Incontinence: Involuntary leakage during activities that increase intra-abdominal pressure (e.g., coughing, sneezing).

Urge Incontinence: Sudden, intense urge to urinate followed by involuntary leakage.

Overflow Incontinence: Continuous dribbling of urine with a sensation of incomplete bladder emptying.

Functional Incontinence: Incontinence related to physical or cognitive impairment, despite normal bladder function.

According to **NICE guidelines**, a combination of history-taking, bladder diaries, and simple investigations (e.g., urinalysis, PVR) is often sufficient for diagnosing the type of urinary incontinence.

6. First-Line Therapy According to Guidelines

The management of urinary incontinence depends on the type of incontinence and the severity of symptoms. Treatment options include lifestyle changes, pelvic floor exercises, medications, and surgical interventions.

Stress Incontinence:

a) Pelvic Floor Muscle Training (PFMT):

Action: Exercises to strengthen the pelvic floor muscles, improving bladder control.

Duration: Recommended for at least 3 months, with guidance from a physiotherapist.

Outcome: Effective in reducing leakage in women with mild to moderate stress incontinence.

b) Lifestyle Modifications:

Action: Weight loss (if overweight), reducing caffeine and alcohol intake, and managing constipation.

Outcome: Reduces pressure on the bladder and improves symptoms.

c) Surgical Options (if conservative measures fail):

Midurethral Sling Surgery:

Action: Placement of a mesh sling to support the urethra.

Outcome: Provides long-term relief from stress incontinence in appropriate candidates.

Colposuspension:

Action: Surgical suspension of the bladder neck to prevent leakage during physical activity.

Outcome: Effective in managing stress incontinence.

Urge Incontinence (Overactive Bladder):

a) Bladder Training:

Action: Scheduled voiding with gradual increases in the time between urinations, combined with pelvic floor exercises.

Outcome: Improves bladder control and reduces urgency.

b) Antimuscarinic Medications (e.g., Oxybutynin, Tolterodine):

Action: Reduce involuntary bladder contractions by blocking muscarinic receptors in the bladder.

Dose: Oxybutynin 2.5–5 mg two to three times daily.

Outcome: Reduces urgency and frequency of urination, though side effects such as dry mouth and constipation are common.

c) Beta-3 Agonists (e.g., Mirabegron):

Action: Relaxes bladder muscles to increase bladder capacity.

Dose: Mirabegron 50 mg once daily.

Outcome: Effective in reducing symptoms of urgency without the anticholinergic side effects of antimuscarinics.

Overflow Incontinence:

a) Intermittent Self-Catheterisation:

Action: Regular catheterisation to fully empty the bladder.

Outcome: Reduces the risk of urinary retention and overflow incontinence.

b) Treatment of Underlying Causes:

Prostate Medications (in men):

Action: Alpha-blockers (e.g., Tamsulosin) relax the muscles in the prostate and bladder neck to improve urine flow.

Outcome: Reduces symptoms of overflow incontinence due to benign prostatic hyperplasia (BPH).

Functional Incontinence:

a) Addressing Mobility and Accessibility Issues:

Action: Provide mobility aids, improve access to toilet facilities (e.g., bedside commodes), and ensure caregiver support.

Outcome: Reduces the risk of incontinence due to mobility or cognitive limitations.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Antimuscarinics: Caution in elderly patients due to the risk of cognitive impairment, confusion, and constipation, especially in those with dementia.

Surgical Interventions: Surgery is generally contraindicated in patients who are frail or have significant comorbidities that increase surgical risk.

b) Second-Line Therapy:

Botulinum Toxin Injections:

Indication: For patients with refractory overactive bladder (urge incontinence) who do not respond to medications.

Mechanism: Injected into the bladder muscle, reducing overactive contractions.

Outcome: Provides long-lasting relief but requires repeat treatments.

Sacral Nerve Stimulation:

Indication: For severe urge incontinence that does not respond to other treatments.

Mechanism: Electrical stimulation of the sacral nerves improves bladder control.

Outcome: Reduces incontinence episodes and improves quality of life.

8. Routine Monitoring and Follow-Up

a) Follow-Up Appointments:

Patients should be followed up regularly to assess the effectiveness of treatments, monitor for side effects, and adjust management plans as needed.

b) Bladder Diary Review:

Reassess bladder diaries at follow-up to monitor changes in voiding patterns, frequency, and incontinence episodes.

c) Medication Monitoring:

Patients on antimuscarinic or other medications should be monitored for side effects, including dry mouth, constipation, and cognitive impairment.

d) Pelvic Floor Strength Monitoring:

For those undergoing pelvic floor muscle training, reassess pelvic floor strength and adherence to exercises at follow-up appointments.

9. Complications of Urinary Incontinence

a) **Skin Breakdown and Infections:**

Chronic urinary leakage can lead to skin irritation, breakdown, and an increased risk of infections such as cellulitis and urinary tract infections.

b) **Falls and Injuries:**

Patients with urgency or nocturia may rush to the toilet, increasing their risk of falls and fractures, particularly in the elderly.

c) **Social Isolation and Depression:**

Urinary incontinence can cause embarrassment, leading to social withdrawal, reduced quality of life, and an increased risk of depression.

d) **Urinary Retention:**

Untreated overflow incontinence can lead to severe urinary retention, requiring catheterisation and increasing the risk of urinary tract infections.

Summary of Key Points for Urinary Incontinence

Urinary incontinence in the elderly can be classified into stress, urge, overflow, and functional incontinence, with distinct underlying causes and treatment strategies.

Diagnosis is based on patient history, bladder diaries, physical examination, and simple investigations such as urinalysis and PVR measurement.

First-line treatments include **pelvic floor muscle training** for stress incontinence, **bladder training** and **antimuscarinics** for urge incontinence, and **catheterisation** for overflow incontinence.

Regular follow-up and monitoring are essential to assess treatment efficacy, manage side effects, and prevent complications such as skin breakdown or infections.

56. Vertigo

1. Detailed Definition of Vertigo

Vertigo is a subtype of dizziness characterised by the false sensation of spinning or movement, either of the patient or their surroundings. It can result from disturbances in the vestibular system, which includes the inner ear, vestibular nerve, and brain structures responsible for balance. Vertigo is common in the elderly and can be caused by peripheral or central vestibular disorders.

Peripheral Vertigo: Involves the inner ear or vestibular nerve, commonly caused by conditions like **benign paroxysmal positional vertigo (BPPV)**, **Ménière's disease**, or **vestibular neuritis**.

Central Vertigo: Caused by dysfunction within the brain, often related to conditions such as **stroke**, **multiple sclerosis**, or **brainstem lesions**.

Vertigo is often associated with nausea, vomiting, and difficulty maintaining balance, leading to an increased risk of falls in elderly patients.

2. Common Presenting Complaints and Symptoms

Elderly patients with vertigo typically present with:

a) **Sensation of Spinning or Motion:**

The patient may feel as though they or their surroundings are moving or spinning, particularly when changing positions (e.g., rolling over in bed or standing up).

b) **Balance Problems and Gait Instability:**

Difficulty walking, feeling unsteady, or a sensation of being pulled to one side. This increases the risk of falls.

c) **Nausea and Vomiting:**

Accompanies the vertiginous sensations, particularly in acute episodes.

d) **Hearing Loss or Tinnitus:**

In cases such as Ménière's disease, patients may also report hearing loss, ringing in the ears, or a feeling of fullness in one ear.

e) **Visual Disturbances:**

Blurred vision or difficulty focusing during episodes of vertigo due to oscillopsia (a sensation that the environment is moving).

f) **Triggers or Positional Changes:**

Symptoms may worsen with head movement, turning, or positional changes, especially in **BPPV**.

g) **Recent Viral Illness:**

A history of a recent upper respiratory infection may precede **vestibular neuritis**, which can cause sudden-onset vertigo.

3. First-Line Investigations

A detailed history and clinical examination are essential for diagnosing the cause of vertigo. In some cases, further investigations are needed to rule out serious underlying conditions.

a) **Dix-Hallpike Manoeuvre** (for BPPV):

What it examines: Provokes vertigo by moving the patient from a seated to a supine position with the head turned to one side.

Purpose: Diagnoses BPPV by reproducing vertigo and observing nystagmus (involuntary eye movements), which is characteristic of this condition.

b) **Head Impulse Test (HIT):**

What it examines: Assesses the vestibulo-ocular reflex by moving the patient's head quickly and observing eye movements.

Purpose: Detects peripheral vestibular dysfunction, as seen in vestibular neuritis or labyrinthitis.

c) Romberg and Unterberger Tests:

What it examines: Assesses balance and gait.

Purpose: Positive results (falling to one side or difficulty maintaining balance with eyes closed) indicate vestibular dysfunction.

d) Audiometry:

What it examines: Measures hearing levels and detects hearing loss.

Purpose: Identifies hearing impairment associated with conditions like Ménière's disease.

e) MRI Brain (if central cause suspected):

What it examines: Brain structures, particularly the brainstem and cerebellum.

Purpose: Rules out central causes of vertigo, such as stroke, brainstem lesions, or tumours.

f) CT Brain (if stroke or trauma is suspected):

What it examines: Brain structures for evidence of bleeding or infarction.

Purpose: Rapidly identifies stroke or other structural abnormalities in patients with acute onset of vertigo and neurological symptoms.

g) Vestibular Function Tests (if indicated):

What it examines: Measures the function of the vestibular system through caloric testing, electronystagmography, or rotary chair testing.

Purpose: Provides detailed information about vestibular dysfunction in cases where the diagnosis is unclear.

4. Explanation of Investigations

a) Dix-Hallpike Manoeuvre:

This test is the gold standard for diagnosing **BPPV**. It involves quickly changing the patient's head position to provoke vertigo and observe the direction of nystagmus. A positive result confirms a diagnosis of BPPV, with nystagmus typically lasting less than 60 seconds.

b) Head Impulse Test (HIT):

This test assesses the integrity of the vestibulo-ocular reflex, which helps stabilise vision during head movements. A positive HIT (corrective eye movement) indicates a peripheral vestibular lesion, such as in **vestibular neuritis**.

5. Diagnostic Criteria for Vertigo

Peripheral Vertigo is diagnosed based on:

BPPV: Diagnosed with a positive Dix-Hallpike test, where vertigo and nystagmus are triggered by specific head movements.

Ménière's Disease: Diagnosed by episodic vertigo lasting minutes to hours, accompanied by hearing loss, tinnitus, and aural fullness.

Vestibular Neuritis: Sudden-onset vertigo, often following a viral illness, with positive head impulse test and no hearing loss.

Central Vertigo is suspected if:

Neurological symptoms such as double vision, weakness, or difficulty speaking accompany vertigo.

Vertigo is persistent and does not improve with positional changes or specific manoeuvres.

MRI or CT scans show evidence of a central lesion (e.g., stroke, tumour).

6. First-Line Therapy According to Guidelines

The treatment of vertigo depends on the underlying cause, and management may include medications, vestibular rehabilitation, and specific manoeuvres.

Benign Paroxysmal Positional Vertigo (BPPV):

a) Epley Manoeuvre:

Action: A series of head movements designed to reposition the displaced otoliths (calcium crystals) in the inner ear back into the correct location.

Outcome: Provides immediate relief of symptoms in the majority of BPPV cases.

b) Brandt-Daroff Exercises:

Action: Exercises performed at home that involve repeated positional changes to desensitise the vestibular system.

Outcome: Useful in patients with persistent or recurrent BPPV to reduce symptoms over time.

Ménière's Disease:

a) Dietary Modifications:

Action: Low-salt diet and avoidance of caffeine and alcohol to reduce fluid buildup in the inner ear.

Outcome: Helps reduce the frequency of Ménière's attacks.

b) Diuretics (e.g., hydrochlorothiazide):

Action: Reduces endolymphatic fluid volume in the inner ear.

Dose: Hydrochlorothiazide 25-50 mg orally once daily.

Outcome: Prevents or reduces the frequency of vertigo episodes.

c) **Betahistine:**

Action: A histamine analogue that improves blood flow to the inner ear and reduces endolymphatic pressure.

Dose: Betahistine 16 mg three times daily.

Outcome: Reduces the frequency and severity of vertigo attacks.

Vestibular Neuritis:

a) **Vestibular Suppressants (e.g., Prochlorperazine, Meclizine):**

Action: Reduces symptoms of vertigo and nausea by acting on the central nervous system.

Dose: Prochlorperazine 5-10 mg orally three times daily.

Outcome: Provides short-term relief of acute vertigo but should not be used long-term as it delays vestibular compensation.

b) **Corticosteroids** (if early in the course):

Action: Reduces inflammation in the vestibular nerve.

Dose: Prednisolone 50 mg daily for 5 days, then tapering.

Outcome: May improve recovery in the acute phase of vestibular neuritis.

c) **Vestibular Rehabilitation:**

Action: Exercises designed to promote central compensation for loss of vestibular function.

Outcome: Improves balance, reduces dizziness, and enhances recovery after acute vestibular dysfunction.

Central Vertigo:

a) **Treat Underlying Cause:**

For **stroke**, immediate treatment with thrombolysis or thrombectomy may be required.

For **tumours**, surgical intervention or radiotherapy may be indicated.

b) **Vestibular Rehabilitation:**

Action: Physical therapy exercises aimed at retraining the brain to compensate for central vestibular dysfunction.

Outcome: Improves balance and reduces dizziness in patients with central causes of vertigo.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Vestibular Suppressants: Prolonged use is contraindicated in chronic vertigo because it delays central compensation and recovery. These medications should be used only for acute episodes.

b) **Second-Line Therapy:**

Intratympanic Steroid Injections (for Ménière's Disease):

Indication: For patients with refractory Ménière's disease.

Mechanism: Reduces inflammation in the inner ear.

Outcome: Provides relief from vertigo attacks.

Surgical Options (for refractory cases):

Indication: For patients with severe, disabling vertigo that does not respond to medical treatment.

Options: Endolymphatic sac surgery (for Ménière's disease) or vestibular nerve section (for intractable vertigo).

Outcome: Reduces or eliminates vertigo but may lead to some hearing loss.

8. Routine Monitoring and Follow-Up

a) **Symptom Monitoring:**

Regular follow-up is important to assess symptom progression, particularly in patients with chronic vertigo. Monitor for the development of new neurological symptoms.

b) **Hearing Assessments:**

Patients with Ménière's disease or vestibular neuritis should have regular hearing evaluations to monitor for any progression of hearing loss.

c) **Rehabilitation Progress:**

Patients undergoing vestibular rehabilitation should be monitored for improvement in balance and reduction in dizziness. Adjust exercises as necessary to promote recovery.

9. Complications of Vertigo in the Elderly

a) **Falls and Injuries:**

The elderly are particularly prone to falls due to balance issues related to vertigo, increasing the risk of fractures and other injuries.

b) **Social Isolation and Depression:**

Chronic vertigo can lead to reduced mobility, social withdrawal, and increased risk of depression due to the disabling nature of the symptoms.

c) **Hearing Loss:**

Conditions like Ménière's disease may lead to progressive hearing loss, affecting communication and quality of life.

d) **Chronic Dizziness:**

In cases where vertigo persists, patients may develop chronic dizziness and unsteadiness, significantly impacting daily activities.

Summary of Key Points for Vertigo in the Elderly

Vertigo in the elderly is commonly caused by **BPPV**, **Ménière's disease**, or **vestibular neuritis**, though central causes such as stroke must be considered.

Diagnosis is based on clinical manoeuvres like the **Dix-Hallpike test** and **Head Impulse Test**, with MRI or CT scans reserved for suspected central causes.

First-line treatment includes **Epley manoeuvre** for BPPV, **betahistine** for Ménière's disease, and vestibular suppressants for acute vertigo.

Vestibular rehabilitation is essential in promoting recovery and reducing the risk of chronic dizziness or falls.

Cardiology

57. Angina

1. Definition of Angina:

Angina pectoris is chest pain caused by myocardial ischemia due to reduced coronary blood flow. This typically results from atherosclerosis in the coronary arteries. Angina is classified into:

- **Stable angina:** Predictable chest pain during exertion or stress, relieved by rest or nitroglycerine.
- **Unstable angina:** A part of acute coronary syndrome (ACS), characterized by unpredictable chest pain that can occur at rest.

2. Common Presenting Complaints and Symptoms:

- **Chest pain or discomfort:** Often described as tight, pressure-like, or squeezing. Pain may radiate to the jaw, neck, or arms.
- **Symptoms triggered by:** Physical exertion, emotional stress, or exposure to cold.
- **Duration:** Typically lasts less than 15 minutes and is relieved by rest or glyceryl trinitrate (GTN).
- **Other symptoms:** Shortness of breath, nausea, fatigue, or dizziness.

For **unstable angina**, symptoms occur unpredictably and can occur at rest or with minimal exertion.

3. First-Line Investigations:

a) ECG (Electrocardiogram):

- **Purpose:** To detect ischemic changes such as ST depression or T-wave inversions during an episode of angina.
- **Explanation:** Ischemic changes may be evident only during an episode of chest pain.

b) Exercise Tolerance Test (ETT):

- **Purpose:** To assess the heart's response to exercise.

- **Explanation:** This test is positive if angina symptoms are provoked and/or ECG changes are seen during exercise.

c) Coronary Angiography:

- **Purpose:** To visualize coronary artery blockages and assess their severity.
- **Explanation:** Used in cases of high-risk or refractory angina, or when considering revascularization.

d) Blood Tests:

- **Troponins:** To rule out myocardial infarction (MI) in cases of suspected unstable angina.
- **Lipid profile:** To assess cardiovascular risk factors.
- **HbA1c and fasting glucose:** To screen for diabetes.

4. Diagnostic Criteria:

Stable Angina:

- Clinical diagnosis based on chest pain that is predictable, triggered by exertion, and relieved by rest or GTN.
- Investigations such as stress testing or coronary angiography confirm the presence of coronary artery disease (CAD).

Unstable Angina:

- New or worsening chest pain, often occurring at rest.
- **ECG** may show ischemic changes, but **troponins** are not elevated (differentiating it from NSTEMI).

5. First-Line Therapy for Stable Angina:

a) General Pharmacological Therapy:

According to **NICE 2011 guidelines**, all patients with stable angina should receive the following medications, unless contraindicated:

1. **Aspirin (75mg once daily):**
 - **Mechanism:** Inhibits cyclooxygenase-1 (COX-1), reducing thromboxane A2, which prevents platelet aggregation and reduces the risk of thrombus formation.
2. **Statin (e.g., Atorvastatin 20-80mg once daily):**
 - **Mechanism:** Inhibits HMG-CoA reductase, lowering cholesterol synthesis, stabilizing atherosclerotic plaques, and reducing cardiovascular events.
 - Statins are essential in reducing LDL cholesterol levels and cardiovascular risk.
3. **Sublingual Glyceryl Trinitrate (GTN):**
 - **Mechanism:** A short-acting nitrate that dilates coronary arteries, improving blood flow and relieving ischemic pain.
 - **Usage:** Administered during an angina episode (1–2 sprays or tablets under the tongue). Patients should be advised to sit down before taking it to avoid dizziness due to blood pressure lowering.

b) Antianginal Drug Therapy:

NICE recommends starting with either a **beta-blocker** or a **calcium channel blocker** as first-line therapy. The choice depends on patient comorbidities, contraindications, and personal preferences.

6. Beta-Blockers vs. Calcium Channel Blockers:

Beta-Blockers (e.g., Bisoprolol 2.5-10mg once daily):

- **Mechanism:** Decreases heart rate and myocardial oxygen demand by blocking beta-adrenergic receptors, reducing workload on the heart.

- **Indication:** First-line for patients without contraindications (e.g., asthma).
- **Dosage:** Start at a low dose and titrate up to the maximum tolerated dose (e.g., Atenolol 50-100mg once daily).
- **Contraindications:** Avoid in patients with asthma, severe COPD, bradycardia, or heart block.

Calcium Channel Blockers:

- **Rate-limiting (e.g., Verapamil, Diltiazem):**
 - **Mechanism:** Slows heart rate and reduces myocardial oxygen demand by inhibiting calcium entry into cardiac and vascular smooth muscle cells.
 - **Indication:** First-line if beta-blockers are contraindicated or not tolerated.
 - **Contraindication:** **Do not combine verapamil with beta-blockers** due to the risk of **complete heart block**.
- **Dihydropyridines (e.g., Amlodipine, Nifedipine):**
 - **Mechanism:** Vasodilates coronary arteries and peripheral vasculature.
 - **Usage:** If combined with a beta-blocker, use a **long-acting dihydropyridine** (e.g., Amlodipine) to avoid bradycardia.

7. Second-Line Therapy for Angina:

If patients do not achieve adequate symptom control with monotherapy, consider the following combinations or second-line drugs:

a) Long-acting Nitrates (e.g., Isosorbide Mononitrate 30-120mg once daily):

- **Mechanism:** Provides prolonged vasodilation, reducing myocardial oxygen demand.
- **Nitrate Tolerance:** Patients should use an asymmetric dosing schedule (e.g., morning dose and afternoon dose) to maintain a nitrate-free interval of 10-14 hours to avoid tolerance.

b) Ivabradine (5-7.5mg twice daily):

- **Mechanism:** Inhibits the funny current (If) in the sinoatrial node, reducing heart rate without affecting blood pressure or contractility.
- **Indication:** For patients who cannot tolerate beta-blockers or calcium channel blockers.

c) Nicorandil (10-20mg twice daily):

- **Mechanism:** A potassium channel activator that causes vasodilation and reduces myocardial oxygen demand.
- **Indication:** Add-on therapy in patients with refractory angina.

d) Ranolazine (500-1000mg twice daily):

- **Mechanism:** Inhibits late sodium currents, improving myocardial relaxation and reducing ischemia.
- **Indication:** Useful in patients who remain symptomatic despite first-line treatments.

8. Nitrate Tolerance:

Many patients who take **nitrates** develop tolerance, meaning the drugs become less effective over time. To prevent this:

- **NICE advises** an asymmetric dosing interval with **standard-release isosorbide mononitrate** to maintain a nitrate-free period of 10-14 hours each day.
- This effect is **not seen** with once-daily modified-release isosorbide mononitrate formulations.

9. Combining Drugs in Refractory Angina:

If a patient remains symptomatic despite monotherapy with a beta-blocker or a calcium channel blocker:

- **Add the other drug class:** For example, if on a beta-blocker, add a calcium channel blocker and vice versa.
- If patients are on both a beta-blocker and a calcium channel blocker but still symptomatic, a **third agent** (e.g., long-acting nitrate, ivabradine, nicorandil, or ranolazine) can be considered while awaiting **PCI** or **CABG**.

10. Routine Monitoring:

- **Blood pressure:** Regularly check in patients on beta-blockers, ACE inhibitors, or calcium channel blockers.
- **Lipid profile:** Monitor lipid levels to assess the efficacy of statin therapy.
- **Renal function:** Especially in patients on ACE inhibitors or angiotensin receptor blockers (ARBs).
- **ECG:** Repeat if symptoms worsen or if new ischemic changes are suspected.

11. Lifestyle Modifications:

- **Smoking cessation:** Reduces cardiovascular risk.
- **Diet:** A heart-healthy diet rich in fruits, vegetables, and whole grains, and low in saturated fats, is recommended.
- **Physical activity:** Regular moderate exercise, while avoiding activities that provoke angina.
- **Weight management:** Helps reduce cardiac workload and overall risk factors.

58. Acute Coronary Syndrome (ACS)

1. Definition of Acute Coronary Syndrome (ACS):

Acute Coronary Syndrome (ACS) is a term used to describe a spectrum of conditions caused by decreased blood flow in the coronary arteries, leading to ischemia and potential myocardial infarction (MI). ACS encompasses three clinical entities:

- **ST-elevation myocardial infarction (STEMI):** ST-segment elevation on ECG with elevated biomarkers indicating myocardial necrosis.
- **Non-ST-elevation myocardial infarction (NSTEMI):** ECG changes without ST-segment elevation, but with raised biomarkers of myocardial damage.
- **Unstable angina (UA):** Similar clinical presentation as NSTEMI but without elevated cardiac biomarkers.

ACS is a medical emergency requiring prompt diagnosis and management to restore blood flow to the heart and minimize myocardial damage.

2. Common Presenting Complaints and Symptoms:

- **Chest pain:** Central, crushing, or squeezing pain lasting ≥ 20 minutes, often radiating to the left arm, jaw, or back.
- **Dyspnoea:** Shortness of breath, especially with exertion.
- **Diaphoresis** (excessive sweating)
- **Nausea and vomiting**
- **Palpitations** or dizziness
- **Fatigue or weakness** (particularly in women and elderly patients)
- **Atypical symptoms** (more common in diabetic and elderly patients), such as epigastric pain or silent MI without overt symptoms.

3. First-Line Investigations:

a) ECG (Electrocardiogram):

- **Purpose:** The primary diagnostic tool to detect ischemic changes.
- **STEMI Criteria:**
 - ST-elevation in ≥ 2 contiguous leads, with thresholds:
 - ≥ 2.5 mm in men under 40 years (V2-V3).
 - ≥ 2 mm in men over 40 years (V2-V3).
 - ≥ 1.5 mm in women (V2-V3).
 - ≥ 1 mm in other leads.
 - New left bundle branch block (LBBB) may also be indicative of STEMI.

b) Cardiac Troponins (T or I):

- **Purpose:** Biomarkers of myocardial necrosis.
- **Explanation:** Troponins are proteins released when myocardial cells are damaged. Elevated troponin levels are diagnostic of NSTEMI or STEMI but not of unstable angina.

c) Chest X-ray (CXR):

- **Purpose:** To rule out differential diagnoses such as aortic dissection or pneumothorax, and assess for heart failure.

d) Bloods:

- **Full Blood Count (FBC):** To check for anaemia or infection.
- **Urea & Electrolytes (U&Es):** To assess renal function and electrolyte balance.
- **Liver Function Tests (LFTs):** Relevant when using hepatotoxic drugs like statins.
- **Lipid Profile:** For cardiovascular risk assessment.
- **Glucose and HbA1c:** To screen for diabetes.

e) Coronary Angiography:

- **Purpose:** The definitive imaging to evaluate coronary artery blockages. Indicated urgently in high-risk patients, particularly those with NSTEMI or unstable angina.

4. Diagnostic Criteria:

STEMI:

- **ECG findings:** ST-elevation or new LBBB.
- **Elevated biomarkers:** Troponins rise significantly.
- **Symptoms:** Persistent chest pain lasting ≥ 20 minutes.

NSTEMI:

- **ECG findings:** ST-depression, T-wave inversion, or no significant changes.
- **Elevated biomarkers:** Troponins are elevated, but no ST-elevation.

Unstable Angina:

- **ECG findings:** May be normal or show transient ischemic changes.
- **Normal biomarkers:** No elevation in troponin levels, despite chest pain.

5. First-Line Therapy:

Common Management for All ACS Patients:

- **Aspirin 300mg:** Irreversibly inhibits cyclooxygenase-1 (COX-1), reducing thromboxane A2 and platelet aggregation.
- **Oxygen therapy:** Only indicated if oxygen saturations fall below 94% (following the British Thoracic Society guidelines).
- **Morphine:** Only for severe pain, as routine use may have adverse outcomes. Administer cautiously with antiemetics.

- **Nitrates** (sublingual or intravenous): Relieve chest pain and reduce myocardial oxygen demand by dilating coronary vessels. Caution in hypotension.

6. Specific Management of STEMI:

Percutaneous Coronary Intervention (PCI):

- **Indication:** Primary PCI is preferred within 12 hours of symptom onset and within 120 minutes of first medical contact.
 - **Drug-eluting stents (DES)** are favoured over bare-metal stents due to lower restenosis rates.
 - **Radial access** is preferred over femoral access for PCI due to lower complication rates.

Fibrinolysis:

- **Indication:** If PCI is not available within 120 minutes, fibrinolysis should be administered within 12 hours of symptom onset.
 - An ECG should be repeated after 60-90 minutes to assess ST-segment resolution. Failure to resolve may require rescue PCI.

Antiplatelet Therapy (Dual Antiplatelet Therapy):

- **Prasugrel (if not anticoagulated)** or **clopidogrel** (if on anticoagulants) are added to aspirin to inhibit platelet aggregation.
- **Unfractionated heparin:** Given during PCI to prevent thrombus formation.

7. Management of NSTEMI and Unstable Angina:

Initial Management:

- **Fondaparinux** (an antithrombin) should be offered to patients who are not immediately undergoing angiography and are not at high bleeding risk.
- **Unfractionated heparin** if creatinine > 265 µmol/L or immediate angiography is planned.

Risk Stratification:

- **GRACE score:** Used to assess the risk of future adverse cardiovascular events, guiding further management.
 - Immediate angiography is warranted for clinically unstable patients.
 - Angiography within 72 hours for patients with a GRACE score >3% (intermediate or high risk).

Dual Antiplatelet Therapy:

- **Ticagrelor** or **Prasugrel** is recommended for most patients in addition to aspirin.
- **Clopidogrel** is used for those at high bleeding risk or taking oral anticoagulants.

8. Contraindications and Second-Line Therapy:

Contraindications to Aspirin:

- **GI bleeding or hypersensitivity.**
- **Second-line:** P2Y12 inhibitors (e.g., clopidogrel) can be used in isolation.

Contraindications to Fibrinolysis:

- **Absolute contraindications:** History of haemorrhagic stroke, active bleeding, aortic dissection.
- **Second-line:** Primary PCI is always preferred if fibrinolysis is contraindicated or unavailable within 120 minutes.

9. Routine Monitoring:

- **Serial ECGs:** To assess for ischemic changes or reperfusion after treatment.
- **Cardiac enzymes:** Repeat troponin levels to monitor the extent of myocardial injury.
- **Renal function:** Regularly check U&Es, especially if the patient is on ACE inhibitors, heparin, or other nephrotoxic medications.
- **Liver function tests:** For patients on statins or other hepatically cleared drugs.
- **Blood glucose monitoring:** Particularly important in diabetic patients.
- **Blood pressure:** Especially in patients treated with beta-blockers or nitrates.

59. Cardiac Arrest

1. Definition of Cardiac Arrest:

Cardiac arrest is defined as the sudden cessation of effective cardiac function, leading to loss of circulation, consciousness, and breathing. It is an immediate life-threatening emergency requiring prompt recognition and treatment to restore cardiac function. The primary underlying causes are often:

- **Ventricular fibrillation (VF)**
- **Pulseless ventricular tachycardia (pulseless VT)**
- **Asystole**
- **Pulseless electrical activity (PEA)**

2. Common Presenting Complaints and Symptoms:

- **Sudden collapse**
- **Loss of consciousness**
- **No pulse or detectable circulation**
- **No breathing or gasping (agonal respirations)**
- **Unresponsiveness to external stimuli**

Symptoms leading up to the arrest may include:

- **Chest pain**
- **Shortness of breath**
- **Palpitations**
- **Light-headedness or dizziness**

Once cardiac arrest occurs, immediate recognition and initiation of resuscitation are critical.

3. First-Line Investigations:

In the setting of cardiac arrest, diagnostic investigations are performed alongside ongoing resuscitative efforts.

a) Electrocardiogram (ECG):

- **Purpose:** To identify the rhythm and classify the arrest as **shockable** (VF/pulseless VT) or **non-shockable** (asystole/PEA).
- **Explanation:** The ECG guides immediate management:
 - **Shockable rhythms:** VF and pulseless VT, which require defibrillation.
 - **Non-shockable rhythms:** Asystole and PEA, which require continuous CPR without defibrillation.

b) Blood Gas Analysis (ABG or VBG):

- **Purpose:** To assess oxygenation, carbon dioxide levels, and acid-base status.
- **Explanation:** These parameters help identify underlying causes (e.g., acidosis, hyperkalaemia) and guide further treatment.

c) Serum Electrolytes (U&Es):

- **Purpose:** Identify electrolyte imbalances such as hyperkalaemia or hypokalaemia, which can trigger arrhythmias.
- **Explanation:** Correcting electrolyte disturbances is crucial to resolving the arrest.

d) Blood Glucose:

- **Purpose:** To check for severe hypoglycaemia, which is a reversible cause of cardiac arrest.

e) Troponins:

- **Purpose:** Elevated levels suggest myocardial infarction as a potential cause of the arrest.

4. Diagnosis Criteria:

The diagnosis of cardiac arrest is made clinically with the following findings:

- **Unresponsiveness**
- **No palpable pulse**
- **Absence of effective breathing**
- **ECG confirmation of a shockable or non-shockable rhythm**

Immediate CPR and defibrillation (if indicated) should be initiated, based on the rhythm classification.

5. First-Line Therapy (Adult Advanced Life Support):

According to the **2021 Resuscitation Council UK guidelines**, cardiac arrest management follows the ALS algorithm, which divides the arrest into **shockable** (VF/pulseless VT) and **non-shockable** (asystole/PEA) rhythms.

Chest Compressions:

- **Compression to ventilation ratio:** 30:2
- **Chest compressions should be continuous while the defibrillator is charging** to minimize interruptions.
- High-quality compressions: 100-120 compressions per minute, depth of 5-6 cm.

Defibrillation (for shockable rhythms - VF/pulseless VT):

- **Single shock followed by immediate 2 minutes of CPR.**
- **If arrest is witnessed in a monitored setting (e.g., coronary care unit),** up to three successive (stacked) shocks may be delivered before resuming CPR.
- **Post-shock:** Resume compressions immediately for 2 minutes before rhythm re-check.

Drug Delivery:

- **IV access** is the preferred route for drug delivery. If IV access cannot be achieved, **intraosseous (IO) access** should be used.
- Drug delivery via a tracheal tube is **no longer recommended**.

Adrenaline:

- **Shockable rhythms (VF/VT):** Administer **1mg adrenaline** after the third shock, then every 3-5 minutes during ALS.
- **Non-shockable rhythms (asystole/PEA):** Administer **1mg adrenaline as soon as possible**, then every 3-5 minutes.

Amiodarone (for shockable rhythms - VF/pulseless VT):

- **300mg IV after the third shock**, with an additional **150mg after the fifth shock** if VF/VT persists.
- **Lidocaine** can be used as an alternative to amiodarone if unavailable or if local protocols favour its use.

Thrombolytics:

- Consider thrombolytic therapy if **pulmonary embolism** is suspected as the cause of the arrest.
 - If thrombolytics are given, **CPR should be continued for 60-90 minutes** to allow the drug to work.

6. Contraindications and Second-Line Therapy:

- **Atropine:** No longer recommended for routine use in asystole or PEA.
- **Defibrillation** is contraindicated in non-shockable rhythms (asystole and PEA). In these cases, focus on high-quality CPR and treating reversible causes.

Reversible Causes of Cardiac Arrest (4 H's and 4 T's):

- **Hypoxia:** Ensure adequate oxygenation via airway management.
- **Hypovolemia:** Rapid fluid resuscitation if suspected (e.g., haemorrhage, dehydration).
- **Hyperkalaemia, Hypokalaemia, Hypoglycaemia, Hypocalcaemia, Acidosis:** Correct metabolic and electrolyte disturbances.
- **Hypothermia:** Rewarm the patient.
- **Thrombosis (coronary or pulmonary):** Suspected MI or PE may require thrombolysis or emergent PCI.
- **Tension pneumothorax:** Perform needle decompression.
- **Tamponade:** Emergency pericardiocentesis.
- **Toxins:** Administer antidotes if poisoning is suspected (e.g., opioid overdose, poisoning).

7. Post-Arrest Care and Monitoring:

After Return of Spontaneous Circulation (ROSC):

- **Oxygen therapy:** Titrate oxygen to achieve saturations of 94-98%, as hyperoxia can be harmful.
- **ECG Monitoring:** Continuous monitoring for arrhythmias or ischemic changes.
- **Targeted Temperature Management (TTM):** Maintain body temperature between 32°C and 36°C for 24 hours to improve neurological outcomes.
- **Blood Pressure Support:** Use inotropes or vasopressors (e.g., adrenaline, noradrenaline) to maintain mean arterial pressure (MAP) and organ perfusion.
- **Bloods and Imaging:**
 - **Lactate levels:** To assess for ongoing tissue hypoxia.
 - **Troponins:** To assess for myocardial infarction.
 - **CT scans:** Consider brain imaging to assess for hypoxic brain injury.

8. Routine Monitoring and Investigations Post-ROSC:

- **Cardiac function:** Echocardiogram to assess for structural abnormalities or wall motion issues.
- **Renal function:** Monitor U&Es to assess for acute kidney injury due to prolonged hypoperfusion.
- **Neurological function:** Regular neurological assessments using the Glasgow Coma Scale (GCS).

Summary of Key ALS Protocol Points (2021 Resuscitation Council UK Guidelines):

- **Shockable rhythms (VF/pulseless VT):** Defibrillation followed by 2 minutes of CPR. Administer adrenaline after the third shock and amiodarone after the third and fifth shocks.

- **Non-shockable rhythms (asystole/PEA):** Immediate CPR with adrenaline as soon as possible.
- **Reversible causes:** Always consider and treat the **4 H's** and **4 T's**.
- **Post-arrest care:** Oxygenation, temperature management, and blood pressure support are key to improving outcomes after ROSC.

60. Atrial Fibrillation (AF)

1. Definition of Atrial Fibrillation (AF):

Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia, characterized by rapid and irregular atrial activity. In AF, the atria do not contract in a coordinated manner, leading to ineffective blood flow and an increased risk of thromboembolism, particularly **stroke**. AF is especially common in the elderly, with a prevalence of around 5% in individuals aged 70-75 years and up to 10% in those aged 80-85 years.

The most critical aspect of managing AF is **stroke prevention**, as the irregular atrial contraction promotes blood stasis and thrombus formation, primarily in the left atrial appendage.

2. Types of Atrial Fibrillation:

- **First detected episode:** When AF is diagnosed for the first time, regardless of whether it is symptomatic or self-terminating.
- **Paroxysmal AF:** Recurrent episodes of AF that terminate spontaneously, usually within 24 hours but lasting less than 7 days.
- **Persistent AF:** Episodes that last more than 7 days and require medical intervention (e.g., cardioversion) for termination.
- **Permanent AF:** Continuous AF where attempts to restore sinus rhythm have failed or are considered inappropriate, and management is focused on rate control and anticoagulation.

3. Common Presenting Complaints and Symptoms:

Symptoms:

- **Palpitations:** Sensation of rapid, irregular heartbeats.
- **Dyspnoea:** Shortness of breath, especially during exertion.
- **Chest pain:** May occur due to reduced coronary blood flow.
- **Fatigue:** Reduced exercise tolerance.
- **Dizziness:** Sometimes accompanied by near-syncope.

Signs:

- **Irregularly irregular pulse:** A hallmark of AF, where the pulse is irregular both in rate and rhythm.

4. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Purpose:** Confirm diagnosis by identifying hallmark findings of AF.
- **Explanation:** AF is characterized by the absence of distinct P waves, replaced by chaotic fibrillatory waves, and an irregularly irregular ventricular response.

b) Echocardiogram:

- **Purpose:** Assess cardiac structure and function, including left atrial size and valvular disease.

- **Explanation:** Helps identify underlying structural abnormalities and assess thromboembolic risk.

c) Thyroid Function Tests (TFTs):

- **Purpose:** Rule out hyperthyroidism, a reversible cause of AF.

d) Blood Tests:

- **Full Blood Count (FBC):** To exclude anaemia or infection as triggers.
- **U&Es:** To check renal function and electrolyte imbalances.
- **Liver Function Tests (LFTs):** For monitoring anticoagulants (particularly warfarin or DOACs).

e) 24-hour Holter Monitoring:

- **Purpose:** Assess the burden of AF in patients with intermittent episodes.

5. Management Goals for Atrial Fibrillation:

Management focuses on two key strategies:

1. **Rate or rhythm control:** Managing the heart rate and attempting to restore normal sinus rhythm if appropriate.
2. **Stroke risk reduction:** Anticoagulation therapy to prevent thromboembolism, particularly stroke.

6. Rate vs. Rhythm Control:

Rate Control:

- **Strategy:** Accept the irregular rhythm but slow the ventricular rate to minimize symptoms and prevent deterioration in cardiac function.
- **First-line agents:**
 - **Beta-blockers (e.g., Bisoprolol):** Reduce heart rate by blocking beta-adrenergic receptors.
 - **Calcium channel blockers (e.g., Diltiazem):** Slow heart rate by blocking calcium entry into pacemaker cells.
 - **Digoxin:** Often used in sedentary or elderly patients, especially if heart failure is present. Less effective during exertion.

Combination therapy:

- If rate control with a single agent is insufficient, **combination therapy** with any two of the following (beta-blocker, calcium channel blocker, digoxin) can be used.

Rhythm Control:

- **Strategy:** Restore and maintain normal sinus rhythm, particularly in younger or symptomatic patients, or those with coexisting heart failure.
- **Methods:**
 - **Electrical cardioversion:** Synchronized direct current (DC) shock to restore sinus rhythm.
 - **Pharmacological cardioversion:** Using antiarrhythmic drugs such as **Amiodarone** or **Flecainide**.

When to use rhythm control:

- First-onset AF (<48 hours).
- AF secondary to a reversible cause.
- Patients with AF and heart failure where rhythm control may improve cardiac function.

7. Cardioversion and Anticoagulation:

Onset < 48 hours:

- If the duration of AF is less than 48 hours, **cardioversion** (electrical or pharmacological) may be performed after heparinization.
- **Anticoagulation:** Patients with stroke risk factors should be started on **lifelong oral anticoagulation**.

Onset > 48 hours:

- **Anticoagulation:** Required for at least 3 weeks before cardioversion or perform a **transoesophageal echocardiogram (TOE)** to exclude left atrial appendage thrombus. If thrombus is excluded, immediate cardioversion can be performed.
- After cardioversion, anticoagulation should be continued for at least 4 weeks, and further treatment depends on stroke risk (assessed by CHA2DS2-VASc).

8. Reducing Stroke Risk in AF:

The risk of stroke in AF patients is stratified using the **CHA2DS2-VASc** score:

Risk Factor	Points
Congestive heart failure	1
Hypertension	1
A2 Age $\geq$ 75 years	2
Diabetes mellitus	1
S2 Stroke/TIA/TE	2
Vascular disease	1
A Age 65–74 years	1
Sex (female)	1

Anticoagulation Recommendations:

- **Score 0:** No treatment needed.
- **Score 1** (males): Consider anticoagulation.
- **Score $\geq$ 2:** Offer anticoagulation.

Anticoagulation options:

1. **Direct Oral Anticoagulants (DOACs):** Apixaban, Dabigatran, Rivaroxaban, Edoxaban.
 - DOACs are preferred over warfarin due to fewer interactions and no need for routine INR monitoring.
2. **Warfarin:** Used if DOACs are contraindicated (e.g., mechanical heart valves).

Aspirin is no longer recommended for stroke prevention in AF.

9. Catheter Ablation:

- **Indication:** For patients with symptomatic AF who fail or prefer not to use antiarrhythmic drugs.
- **Procedure:** Ablation of the electrical pathways in the pulmonary veins to prevent aberrant electrical signals.
- **Anticoagulation:** Patients should be anticoagulated before and after the procedure.

10. Assessing Bleeding Risk:

The **ORBIT** score is now recommended to assess bleeding risk in patients receiving anticoagulation:

Variable	Points
Haemoglobin <130 g/L (males) or <120 g/L (females)	2
Age > 74 years	1
Bleeding history (GI or intracranial)	2
Renal impairment (GFR < 60 mL/min)	1

Interpretation:

- **Low risk (0-2):** Bleeding risk 2.4 per 100 patient-years.
- **Medium risk (3):** Bleeding risk 4.7 per 100 patient-years.
- **High risk (4-7):** Bleeding risk 8.1 per 100 patient-years.

11. Long-Term Management:**Rate control:**

- Most patients are managed with rate control as the first-line strategy unless contraindicated (e.g., heart failure due to AF or reversible AF).

Rhythm control:

- Consider in selected patients where maintaining sinus rhythm is beneficial.

Key updates from the 2021 NICE guidelines highlight the importance of **long-term anticoagulation** based on stroke risk and the increasing use of **catheter ablation** for rhythm control in symptomatic patients.

61. Atrial Arrhythmias

1. Definition of Atrial Arrhythmias:

Atrial arrhythmias are abnormal heart rhythms that originate in the atria (the upper chambers of the heart). These arrhythmias disrupt the regular, coordinated electrical impulses that control the heart's rhythm, often leading to rapid, irregular heartbeats. Atrial arrhythmias encompass a range of conditions that vary in severity and clinical significance.

The most common types of atrial arrhythmias include:

- **Atrial fibrillation (AF)**
- **Atrial flutter**
- **Atrial tachycardia**
- **Multifocal atrial tachycardia (MAT)**

These arrhythmias can result in symptoms like palpitations, dizziness, and shortness of breath, and can lead to serious complications such as stroke or heart failure if not managed properly.

2. Types of Atrial Arrhythmias:

a) Atrial Fibrillation (AF):

- **Description:** The most common sustained atrial arrhythmia, characterized by rapid and irregular atrial electrical activity. The atria quiver rather than contract effectively.
- **Prevalence:** Particularly common in elderly patients, with a strong association with stroke and thromboembolism.
- **Types:** First detected, paroxysmal, persistent, and permanent.

b) Atrial Flutter:

- **Description:** A re-entrant rhythm in the atria, characterized by a regular but rapid atrial rate (often around 300 beats per minute). Unlike AF, atrial flutter has a more organized, sawtooth pattern on ECG.
- **Types:**
 - **Typical atrial flutter:** Originates from a circuit in the right atrium.
 - **Atypical atrial flutter:** Arises from circuits outside the typical pathway.

c) Atrial Tachycardia:

- **Description:** A form of supraventricular tachycardia (SVT) originating from an ectopic focus in the atria, leading to regular, rapid atrial beats (100-250 beats per minute). It is less common than AF and atrial flutter.

d) Multifocal Atrial Tachycardia (MAT):

- **Description:** Characterized by irregular atrial activity with multiple atrial foci, leading to at least three different P-wave morphologies on ECG. It is often seen in patients with severe lung disease, such as chronic obstructive pulmonary disease (COPD).

3. Common Presenting Complaints and Symptoms:

- **Palpitations:** A sensation of a rapid, fluttering, or pounding heartbeat.
- **Dizziness or light-headedness**
- **Shortness of breath** (dyspnoea), especially during physical exertion.
- **Chest discomfort** or angina.
- **Fatigue:** Reduced exercise tolerance, often seen in patients with sustained arrhythmias.
- **Syncope** (fainting), though rare, may occur if the arrhythmia leads to significant hemodynamic compromise.

4. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Purpose:** The primary diagnostic tool for atrial arrhythmias.
- **Findings:**
 - **AF:** Irregularly irregular rhythm with absent P waves and chaotic fibrillatory waves.
 - **Atrial flutter:** Regular "sawtooth" flutter waves at a rate of 250-350 beats per minute, usually with a fixed AV conduction ratio (e.g., 2:1 or 3:1).
 - **Atrial tachycardia:** Atrial rate of 100-250 beats per minute, with distinct P waves preceding each QRS complex.
 - **Multifocal atrial tachycardia (MAT):** Irregular rhythm with at least three different P-wave morphologies.

b) Holter Monitor (24-hour ECG monitoring):

- **Purpose:** Used to diagnose intermittent atrial arrhythmias or assess the burden of arrhythmia over a 24-hour period.

c) Echocardiogram:

- **Purpose:** To assess cardiac structure and function, especially to look for underlying causes such as valvular heart disease, left atrial enlargement, or heart failure.

d) Blood Tests:

- **Thyroid function tests (TFTs):** Hyperthyroidism can precipitate atrial arrhythmias, particularly AF.
- **Urea & Electrolytes (U&Es):** To rule out electrolyte disturbances such as hypokalaemia or hypomagnesemia, which can trigger arrhythmias.
- **Cardiac biomarkers:** If myocardial ischemia is suspected.

5. Management Strategies:

Management of atrial arrhythmias depends on the type, underlying cause, symptoms, and risk of complications such as stroke.

a) Atrial Fibrillation (AF) and Atrial Flutter:

- **Rate Control:**
 - **Beta-blockers (e.g., Bisoprolol 2.5-10mg once daily):** Reduce heart rate by blocking beta-adrenergic receptors.
 - **Calcium channel blockers (e.g., Diltiazem, Verapamil):** Slow AV nodal conduction, reducing heart rate.
 - **Digoxin:** Often used in sedentary patients or those with heart failure.
- **Rhythm Control** (for symptomatic or persistent cases):
 - **Electrical cardioversion:** Direct current shock synchronized with the R wave to restore normal sinus rhythm.
 - **Pharmacological cardioversion:** Amiodarone or Flecainide can be used for rhythm control.
 - **Catheter ablation:** Used in atrial flutter or AF, where aberrant electrical circuits are ablated to prevent recurrence.
- **Anticoagulation** (especially in AF and atrial flutter):
 - Based on **CHA2DS2-VASc score** to assess stroke risk.
 - **Direct Oral Anticoagulants (DOACs)** or **Warfarin** for stroke prevention.

b) Atrial Tachycardia:

- **Rate Control:** Beta-blockers or calcium channel blockers are typically used.

- **Rhythm Control:** Antiarrhythmic medications such as **Flecainide** or **Amiodarone** may be used to terminate or prevent atrial tachycardia. In recurrent cases, **catheter ablation** may be indicated.

c) Multifocal Atrial Tachycardia (MAT):

- **Treatment of underlying condition:** Often associated with pulmonary disease, such as COPD, so optimizing treatment for the underlying condition (e.g., bronchodilators, steroids) is key.
- **Rate Control:** Calcium channel blockers (e.g., Verapamil) or beta-blockers can be used for rate control.

6. Long-Term Management and Stroke Prevention:

Anticoagulation (for AF and Atrial Flutter):

- **CHA2DS2-VASc Score** is used to stratify stroke risk and guide the need for anticoagulation.
- **DOACs** (e.g., Apixaban, Rivaroxaban) or **Warfarin** are used for stroke prevention.
- Long-term anticoagulation is generally recommended for patients with **persistent or permanent AF**, especially those with a high CHA2DS2-VASc score.

Rate vs. Rhythm Control:

- **Rate control** is the preferred strategy for many patients with AF or atrial flutter, aiming to control the ventricular rate without necessarily restoring sinus rhythm.
- **Rhythm control** (e.g., via cardioversion or ablation) is considered in symptomatic patients, especially younger patients, those with heart failure, or those who fail rate control strategies.

Catheter Ablation:

- Indicated for patients with recurrent atrial flutter or AF who are symptomatic and unresponsive to medications or prefer to avoid long-term antiarrhythmic drugs.
- **Atrial flutter ablation** is generally highly successful, with a high cure rate.

7. Lifestyle Modifications:

- **Smoking cessation:** Reduces overall cardiovascular risk and may decrease arrhythmia burden.
- **Limit alcohol intake:** Excessive alcohol consumption is a well-known trigger for atrial arrhythmias, especially AF.
- **Weight loss:** Can reduce the frequency and severity of atrial arrhythmias.
- **Manage hypertension and diabetes:** Optimizing control of these conditions reduces the risk of atrial arrhythmias.

8. Summary of Key Points for Atrial Arrhythmias:

- **Atrial fibrillation (AF)** is the most common sustained arrhythmia, with a significant risk of stroke.
- **Atrial flutter** is a regular, organized atrial arrhythmia with a characteristic "sawtooth" pattern on ECG.
- **Atrial tachycardia** is a rarer form of supraventricular tachycardia that originates from a focal point in the atria.
- **Multifocal atrial tachycardia (MAT)** is commonly seen in patients with underlying lung disease.
- Management of atrial arrhythmias focuses on **rate or rhythm control**, stroke prevention, and treating underlying causes.

- **Anticoagulation** is essential in patients with AF and atrial flutter to prevent stroke, based on their CHA2DS2-VASc score.
- **Catheter ablation** is an option for symptomatic patients with recurrent arrhythmias, especially atrial flutter.

This detailed guide covers the main points related to **atrial arrhythmias**, including their types, diagnostic approach, management strategies, and long-term care considerations. Here is a quick recap of key elements:

1. **Types of Atrial Arrhythmias:** Atrial fibrillation, atrial flutter, atrial tachycardia, and multifocal atrial tachycardia, each with distinct clinical and ECG characteristics.
2. **Symptoms:** Common symptoms include palpitations, shortness of breath, dizziness, and fatigue. In some cases, atrial arrhythmias may be asymptomatic and discovered incidentally.
3. **Diagnosis:** The diagnosis relies heavily on **ECG** findings, with further tests like echocardiography, Holter monitoring, and blood tests to identify underlying causes and guide treatment.
4. **Management:**
 - **Rate control** is the mainstay of treatment for most atrial arrhythmias, particularly in AF and atrial flutter, using beta-blockers, calcium channel blockers, or digoxin.
 - **Rhythm control** strategies (cardioversion and antiarrhythmics) may be considered in specific cases.
 - **Anticoagulation** based on the CHA2DS2-VASc score is crucial in AF and atrial flutter to reduce the risk of stroke.
5. **Catheter Ablation:** This is a key option for patients with symptomatic, recurrent arrhythmias that are unresponsive to medical therapy or those who prefer to avoid long-term medication.
6. **Lifestyle modifications:** These are essential to reducing the frequency of atrial arrhythmias and improving overall cardiovascular health, including weight loss, smoking cessation, and management of hypertension and diabetes.

62. Atrioventricular (AV) Block

1. Definition of Atrioventricular (AV) Block:

Atrioventricular (AV) block, commonly referred to as **heart block**, occurs when there is impaired electrical conduction between the atria and ventricles. Normally, electrical impulses originating in the sinoatrial (SA) node are transmitted through the AV node to the ventricles, resulting in coordinated atrial and ventricular contraction. In AV block, this conduction is delayed, intermittently blocked, or completely disrupted. AV block is classified into three types based on the severity of the conduction impairment: **first-degree**, **second-degree**, and **third-degree (complete)** AV block.

2. Types of Atrioventricular Block:

a) First-Degree AV Block:

- **Definition:** Characterized by a prolonged PR interval (>0.2 seconds) but every P wave is followed by a QRS complex. There is a delay in conduction from the atria to the ventricles, but all impulses eventually reach the ventricles.
- **ECG Findings:** PR interval is greater than 0.2 seconds (5 small squares on the ECG grid), but every atrial impulse is conducted to the ventricles.

- **Clinical Significance:** Asymptomatic and often found incidentally. It is relatively common and typically does not require treatment.

b) Second-Degree AV Block:

- **Definition:** There is intermittent failure of conduction between the atria and ventricles, meaning some P waves are not followed by QRS complexes.
- **Types:**
 - **Type 1 (Mobitz I or Wenckebach):**
 - **Description:** There is a progressive prolongation of the PR interval until a P wave is not followed by a QRS complex (dropped beat).
 - **ECG Findings:** Gradual lengthening of the PR interval, followed by a dropped QRS complex (i.e., a P wave without a subsequent QRS complex). After the dropped beat, the cycle repeats.
 - **Clinical Significance:** Mobitz I is often benign and can be asymptomatic, especially if it occurs during sleep or in athletes. Treatment is typically not needed unless the patient is symptomatic (e.g., dizziness or syncope).
 - **Type 2 (Mobitz II):**
 - **Description:** The PR interval remains constant, but some P waves are not conducted to the ventricles, meaning that P waves occur without a corresponding QRS complex.
 - **ECG Findings:** Constant PR interval, with occasional failure of conduction, resulting in a P wave without a QRS complex (dropped beat).
 - **Clinical Significance:** Mobitz II is more concerning than Mobitz I and often requires intervention, as it can progress to complete heart block. Patients may experience dizziness, syncope, or fatigue, and a permanent pacemaker may be necessary.

c) Third-Degree (Complete) AV Block:

- **Definition:** In complete heart block, there is no conduction of electrical impulses from the atria to the ventricles. The atria and ventricles beat independently, with the atria following the sinus rhythm and the ventricles relying on a slower escape rhythm.
- **ECG Findings:** No association between P waves and QRS complexes (AV dissociation). The atrial rate is faster and independent of the slower ventricular rate, which is generated by an escape rhythm.
- **Clinical Significance:** Third-degree AV block is a medical emergency, especially if the ventricular escape rhythm is too slow to maintain adequate cardiac output. Patients often experience bradycardia, syncope, or heart failure, and immediate intervention, often with pacing, is required.

3. ECG Findings in AV Block Types:

- 1. First-Degree AV Block:**
 - **PR Interval:** Prolonged (>0.2 seconds).
 - **P Wave and QRS Complex:** Every P wave is followed by a QRS complex, with no dropped beats.
- 2. Second-Degree AV Block:**
 - **Type 1 (Mobitz I or Wenckebach):**
 - **PR Interval:** Progressively lengthens with each beat, leading to a dropped QRS complex.

- **Dropped Beats:** After a dropped beat, the PR interval resets and the cycle repeats.
 - **Type 2 (Mobitz II):**
 - **PR Interval:** Constant, but some P waves are not followed by a QRS complex (intermittent conduction failure).
 - **Dropped Beats:** Occasional P waves without subsequent QRS complexes.
3. **Third-Degree AV Block:**
- **P Waves and QRS Complexes:** P waves and QRS complexes occur independently, with no association between the two.
 - **Atrial and Ventricular Rates:** Atrial rate is normal (determined by the SA node), while the ventricular rate is slow (due to an escape rhythm).

4. Symptoms of Atrioventricular Block:

Symptoms vary depending on the degree of block and the patient's underlying health.

- **First-degree AV block:** Often asymptomatic.
- **Second-degree AV block:**
 - **Mobitz I:** May be asymptomatic or cause mild symptoms such as dizziness, especially during exertion.
 - **Mobitz II:** More likely to cause significant symptoms such as light-headedness, fatigue, syncope, and palpitations.
- **Third-degree AV block:** Symptoms are typically more severe and can include bradycardia, fatigue, syncope, dizziness, and in severe cases, **Stokes-Adams attacks** (sudden loss of consciousness).

5. Management of Atrioventricular Block:

First-Degree AV Block:

- **Treatment:** Generally, no treatment is needed for asymptomatic patients. If symptomatic (rare), evaluate for underlying causes (e.g., medications or electrolyte imbalances) and consider modifying treatment.

Second-Degree AV Block:

- **Mobitz I:**
 - **Management:** If asymptomatic, no treatment is required. In symptomatic cases (e.g., syncope), treat underlying causes and monitor with possible pacemaker consideration in severe cases.
- **Mobitz II:**
 - **Management:** Mobitz II carries a higher risk of progression to complete heart block. Most patients require a **permanent pacemaker**, even if asymptomatic, due to the risk of sudden progression to third-degree heart block and the potential for life-threatening bradycardia.

Third-Degree (Complete) AV Block:

- **Management:** Complete heart block is a medical emergency, and immediate intervention is often required.
 - **Temporary pacing** is indicated in acute symptomatic patients (e.g., those with syncope or hemodynamic instability).
 - **Permanent pacemaker** implantation is the definitive treatment for chronic complete heart block.

- **Atropine** may be used acutely to increase heart rate but is often ineffective in third-degree heart block.

6. Common Causes of Atrioventricular Block:

1. **Age-related degeneration** of the conduction system (particularly in elderly patients).
2. **Ischemic heart disease:** Myocardial infarction, especially involving the inferior wall (supplied by the right coronary artery, which also supplies the AV node).
3. **Medications:** Drugs such as beta-blockers, calcium channel blockers, digoxin, and antiarrhythmic agents (e.g., amiodarone) can impair AV conduction.
4. **Infections:** Lyme disease, rheumatic fever, or viral myocarditis can inflame the conduction system and lead to AV block.
5. **Electrolyte imbalances:** Hyperkalaemia and hypokalaemia can impair conduction.
6. **Congenital heart disease:** Some patients may be born with heart defects that affect the conduction system.

Summary of Key Points for Atrioventricular Block:

- **First-degree AV block:** PR interval >0.2 seconds, usually asymptomatic and requires no treatment.
- **Second-degree AV block:**
 - **Mobitz I (Wenckebach):** Progressive prolongation of the PR interval until a beat is dropped, often benign.
 - **Mobitz II:** Constant PR interval with intermittent dropped beats, more serious, often requiring pacemaker placement.
- **Third-degree (complete) AV block:** No conduction between the atria and ventricles, necessitating immediate treatment, often with a permanent pacemaker.

Management depends on the severity of the block, patient symptoms, and underlying causes, with close monitoring and pacemaker therapy being central to treating more severe blocks.

63. Ventricular Tachycardia (VT)

1. Definition of Ventricular Tachycardia (VT):

Ventricular tachycardia (VT) is a rapid heart rhythm originating from the ventricles (the lower chambers of the heart) with a rate typically over 100 beats per minute. VT is caused by abnormal electrical signals in the ventricles that result in inefficient cardiac contractions and reduced cardiac output. VT is a potentially life-threatening arrhythmia, especially if sustained, as it can lead to hemodynamic instability, syncope, and progression to ventricular fibrillation (VF) or sudden cardiac death.

2. Types of Ventricular Tachycardia:

a) Monomorphic VT:

- **Description:** All QRS complexes have the same morphology (shape and size) throughout the tachycardia. This indicates a single re-entrant pathway or ectopic focus in the ventricles.
- **Causes:** Most often associated with structural heart disease such as myocardial infarction (MI), cardiomyopathy, or fibrosis from prior cardiac events.

b) Polymorphic VT:

- **Description:** QRS complexes vary in shape and size, indicating multiple ventricular foci or re-entrant circuits. It is more unstable than monomorphic VT and can rapidly deteriorate into ventricular fibrillation.

- **Causes:** Often associated with conditions like acute ischemia, electrolyte imbalances, and congenital syndromes such as long QT syndrome.

c) Sustained VT:

- **Description:** VT lasting more than 30 seconds or requiring intervention due to hemodynamic instability.
- **Clinical Significance:** More likely to result in syncope, heart failure, or sudden cardiac arrest.

d) Non-sustained VT:

- **Description:** VT that lasts less than 30 seconds and spontaneously terminates without requiring intervention.
- **Clinical Significance:** May be asymptomatic or cause palpitations, but still requires investigation to rule out underlying heart disease.

3. Common Presenting Complaints and Symptoms:

- **Palpitations:** The sensation of rapid, pounding, or irregular heartbeats is often the first symptom.
- **Dizziness or light-headedness:** Caused by reduced cardiac output and subsequent poor cerebral perfusion.
- **Syncope or near-syncope:** Due to severely reduced cardiac output and blood pressure.
- **Chest pain:** Often due to reduced coronary perfusion during VT.
- **Dyspnoea:** Shortness of breath, especially with prolonged or sustained episodes of VT.
- **Fatigue:** Occurs due to inadequate perfusion of vital organs.

In **severe cases**, patients may present with **hemodynamic collapse** and **cardiac arrest**, particularly if VT degenerates into ventricular fibrillation.

4. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Purpose:** Diagnostic tool for VT. ECG findings depend on whether VT is monomorphic or polymorphic.
- **Findings:**
 - **Monomorphic VT:** Regular, wide QRS complexes (>120ms) with a consistent morphology and a rate of over 100 bpm.
 - **Polymorphic VT:** Irregular, varying QRS complex morphology with a rapid ventricular rate. One form of polymorphic VT, **Torsades de Pointes**, shows a characteristic twisting of the QRS complexes around the isoelectric line.
- **Differentiation from SVT with aberrancy:** Important to differentiate VT from supraventricular tachycardia (SVT) with aberrant conduction (e.g., bundle branch block), as the management differs significantly.

b) Blood Tests:

- **Troponins:** To assess for myocardial ischemia or infarction.
- **Electrolytes:** To check for disturbances such as hypokalaemia, hyperkalaemia, or hypomagnesaemia that can trigger VT.
- **Thyroid function tests:** Hyperthyroidism can exacerbate arrhythmias, though less commonly associated with VT.

c) Echocardiogram:

- **Purpose:** To assess structural heart disease, such as cardiomyopathy or reduced left ventricular ejection fraction (LVEF), which increases the risk of VT.

d) Coronary Angiography:

- **Indication:** Performed if VT is suspected to be caused by ischemic heart disease or in patients with known coronary artery disease.

5. Diagnostic Criteria for VT:

VT is diagnosed based on **ECG findings**, which typically show:

- **Wide QRS complexes** (>120ms), with a regular or irregular ventricular rhythm.
- **AV dissociation:** P waves are present but are unrelated to QRS complexes (ventricular and atrial rhythms are independent).
- **Capture and fusion beats:** Seen in some cases of VT, where normal sinus beats intermittently capture the ventricles, resulting in a narrow QRS complex.

Differentiating **VT** from **supraventricular tachycardia (SVT)** with a wide QRS complex is critical, as **VT** is much more dangerous and requires immediate intervention.

6. First-Line Therapy:

a) Acute Management of VT:

1. **Hemodynamically Unstable VT (e.g., hypotension, syncope, chest pain, or heart failure):**
 - **Immediate synchronized electrical cardioversion:**
 - **Mechanism:** Delivers an electrical shock synchronized with the QRS complex to terminate VT and restore sinus rhythm.
 - **Indication:** First-line treatment in unstable VT.
2. **Hemodynamically Stable VT:**
 - **Intravenous antiarrhythmics:**
 - **Amiodarone (150mg IV bolus over 10 minutes, followed by infusion):** A class III antiarrhythmic that prolongs the refractory period and helps terminate VT.
 - **Lidocaine (1-1.5mg/kg IV bolus):** A class IB antiarrhythmic that blocks sodium channels, often used in ischemic VT.
 - **Procainamide (10-17 mg/kg IV over 30 minutes):** A class IA antiarrhythmic that is sometimes used for stable VT if amiodarone is ineffective.
3. **Torsades de Pointes (a type of polymorphic VT):**
 - **Magnesium sulfate (1-2g IV over 15 minutes):**
 - **Mechanism:** Magnesium stabilizes cardiac myocyte membranes and is the treatment of choice for Torsades de Pointes.
 - **Isoprenaline or pacing:** For Torsades related to long QT syndrome, increasing the heart rate can shorten the QT interval.

b) Long-Term Management of VT:

1. **Implantable Cardioverter-Defibrillator (ICD):**
 - **Indication:** Patients with a history of sustained VT, especially those with structural heart disease, ischemic cardiomyopathy, or low LVEF. The ICD monitors heart rhythms and delivers a shock to terminate life-threatening arrhythmias.
2. **Antiarrhythmic Medication:**
 - **Amiodarone:** Often used for long-term rhythm control, especially in patients with ICDs to reduce the frequency of shocks.
 - **Beta-blockers:** Especially in patients with ischemic heart disease, beta-blockers (e.g., Metoprolol) reduce the frequency of ventricular arrhythmias.

3. Catheter Ablation:

- **Indication:** For patients with recurrent, drug-resistant VT. The procedure involves ablating the arrhythmogenic tissue or circuit to prevent recurrence of VT.

7. Common Causes of Ventricular Tachycardia:

1. Ischemic Heart Disease:

- The most common cause, especially in patients with a prior history of myocardial infarction. Scar tissue in the ventricles can create a re-entrant circuit that leads to VT.

2. Cardiomyopathy:

- **Dilated cardiomyopathy** and **hypertrophic cardiomyopathy** can lead to VT due to structural abnormalities and fibrosis in the heart.

3. Electrolyte Imbalances:

- **Hypokalaemia**, **hyperkalaemia**, and **hypomagnesemia** are known triggers for VT.

4. Congenital Long QT Syndrome:

- Patients with prolonged QT intervals are at risk of **Torsades de Pointes**, a type of polymorphic VT.

5. Drug-Induced:

- Certain drugs (e.g., antiarrhythmics, tricyclic antidepressants, and antipsychotics) can prolong the QT interval and lead to VT.

6. Infiltrative Diseases:

- Conditions like **sarcoidosis**, **amyloidosis**, and **hemochromatosis** can involve the myocardium and increase the risk of VT.

8. Routine Monitoring and Long-Term Management:

- **ECG monitoring:** Continuous monitoring in patients with acute VT or those receiving antiarrhythmic medications.
- **ICD follow-up:** Regular checks to ensure the ICD is functioning properly and delivering appropriate therapy when needed.
- **Echocardiogram:** Periodic assessment of cardiac function, especially in patients with underlying cardiomyopathies.
- **Blood tests:** Monitoring electrolyte levels and renal function, especially in patients on medications like amiodarone or other antiarrhythmics.

9. Complications of Ventricular Tachycardia:

- **Hemodynamic instability:** Sustained VT can cause a significant drop in cardiac output, leading to hypotension, dizziness, syncope, or even cardiogenic shock.
- **Progression to ventricular fibrillation (VF):** VT, particularly polymorphic VT or prolonged untreated VT, can degenerate into VF, which is a life-threatening arrhythmia that requires immediate defibrillation.
- **Sudden cardiac death:** If VT is not promptly recognized and treated, it can lead to cardiac arrest and sudden death.
- **Heart failure:** Recurrent or sustained VT can worsen cardiac function, leading to heart failure, especially in patients with underlying structural heart disease.
- **ICD shocks:** Patients with implantable cardioverter-defibrillators (ICDs) may experience frequent or inappropriate shocks, which can be painful and distressing.

10. Long-Term Monitoring and Follow-Up:

1. ICD Monitoring:

- Regular follow-up to check the device's battery life, settings, and whether it has delivered any shocks.
- Adjustments to ICD programming may be needed to prevent unnecessary or inappropriate shocks.

2. Antiarrhythmic Drug Monitoring:

- **Amiodarone:** Long-term use of amiodarone requires regular monitoring of thyroid, liver, and lung function due to potential toxicities.
- **Beta-blockers:** Monitor heart rate and blood pressure, as excessive beta-blockade can cause bradycardia or hypotension.

3. Echocardiography:

- Regular assessment of left ventricular function, especially in patients with cardiomyopathy, to monitor for worsening heart failure.

4. Cardiac Rehabilitation:

- For patients recovering from VT secondary to ischemic heart disease or those who have received an ICD, cardiac rehabilitation can improve outcomes through lifestyle modifications, exercise, and medical management.

5. Lifestyle Modifications:

- **Smoking cessation:** Reduces cardiovascular risk.
- **Dietary changes:** A heart-healthy diet low in sodium and saturated fats can help manage heart disease and reduce the risk of arrhythmias.
- **Exercise:** Regular moderate exercise is encouraged, but patients with an ICD should avoid strenuous physical activity without physician guidance.

11. Summary of Key Points for Ventricular Tachycardia (VT):

- **Ventricular tachycardia (VT)** is a rapid heart rhythm that originates from the ventricles, typically with a rate over 100 beats per minute. It can be life-threatening if not treated promptly.
- VT is classified into **monomorphic** (uniform QRS morphology) and **polymorphic** (varying QRS morphology), with polymorphic VT being more unstable.
- Common causes include **ischemic heart disease, cardiomyopathy, electrolyte imbalances, and long QT syndrome**.
- **ECG** is the primary diagnostic tool, showing wide QRS complexes with an independent atrial and ventricular rate (AV dissociation).
- **Immediate treatment** depends on the patient's hemodynamic stability:
 - For unstable patients: **synchronized cardioversion** is the treatment of choice.
 - For stable patients: **intravenous antiarrhythmic drugs** such as **amiodarone, lidocaine, or procainamide** are used.
 - **Torsades de Pointes** (a form of polymorphic VT) requires treatment with **magnesium sulfate**.
- **Long-term management** includes the use of **ICDs, antiarrhythmic drugs, and catheter ablation** for recurrent or drug-resistant cases.
- **Regular follow-up** is essential for patients with an ICD or those on long-term antiarrhythmics, and lifestyle modifications help reduce the risk of future arrhythmias.

64. Acute Heart Failure

1. Definition of Acute Heart Failure:

Acute heart failure (AHF) is a sudden onset or worsening of symptoms and signs of heart failure, typically due to impaired cardiac function that results in inadequate tissue perfusion and fluid overload. It can occur in patients with chronic heart failure (acute decompensation of chronic heart failure) or as a new presentation (de novo heart failure). AHF is a medical emergency and requires prompt diagnosis and treatment to prevent morbidity and mortality.

2. Common Presenting Complaints and Symptoms:

Symptoms:

- **Dyspnoea (shortness of breath):** The most common symptom, typically worse with exertion or while lying flat (orthopnoea). Paroxysmal nocturnal dyspnoea (PND) may occur, with patients waking up gasping for air.
- **Fatigue and weakness:** Due to reduced cardiac output and inadequate perfusion of tissues.
- **Chest discomfort:** Sometimes present, especially in cases with ischemic causes or concomitant myocardial infarction.
- **Cough:** Often productive with frothy, sometimes pink-tinged sputum due to pulmonary oedema.
- **Swelling:** Peripheral oedema, often in the legs and ankles, and in more severe cases, abdominal swelling due to ascites.

Signs:

- **Tachypnea and respiratory distress:** Patients often appear anxious and short of breath.
- **Crackles (rales):** Heard on lung auscultation, particularly at the bases, indicative of pulmonary oedema.
- **Peripheral oedema:** Swelling of the legs, ankles, and feet.
- **Elevated jugular venous pressure (JVP):** Reflects right-sided heart failure and fluid overload.
- **S3 gallop:** A third heart sound, which is often a sign of volume overload and impaired ventricular function.
- **Cold, clammy extremities:** A sign of poor tissue perfusion in severe cases.

3. Types of Acute Heart Failure:

- **Decompensated Chronic Heart Failure:** Acute exacerbation of pre-existing chronic heart failure, often triggered by infection, arrhythmias, or medication noncompliance.
- **De novo Acute Heart Failure:** New onset heart failure without a prior history, often due to myocardial infarction, severe hypertension, or valvular disease.
- **Acute Pulmonary Oedema:** A subtype characterized by rapid accumulation of fluid in the lungs, leading to severe respiratory distress.
- **Cardiogenic Shock:** A severe form of heart failure where the heart is unable to maintain adequate tissue perfusion, leading to hypotension and multi-organ dysfunction.

4. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Purpose:** To assess for ischemia, arrhythmias, or left ventricular hypertrophy, which can be the underlying cause of acute heart failure.

- **Findings:** May show signs of myocardial ischemia, left bundle branch block, atrial fibrillation, or tachyarrhythmias.

b) Chest X-ray:

- **Purpose:** To look for signs of pulmonary congestion or oedema, cardiomegaly, and pleural effusions.
- **Findings:**
 - Pulmonary oedema (batwing appearance of fluid in the lungs).
 - Cardiomegaly (enlarged heart).
 - Kerley B lines, which indicate interstitial oedema.

c) Blood Tests:

- **Brain Natriuretic Peptide (BNP) or NT-proBNP:**
 - **Purpose:** Elevated BNP or NT-proBNP levels are indicative of heart failure and are useful for diagnosis.
 - **Explanation:** BNP is released by the ventricles in response to increased wall stress.
- **Full Blood Count (FBC):** To exclude anaemia or infection as a trigger.
- **Urea and Electrolytes (U&Es):** To assess renal function and detect electrolyte disturbances, particularly hypokalaemia or hyperkalaemia.
- **Cardiac troponins:** To assess for myocardial infarction as a cause of heart failure.

d) Echocardiogram:

- **Purpose:** To assess cardiac structure and function, including left ventricular ejection fraction (LVEF), valve abnormalities, and the presence of wall motion abnormalities.
- **Findings:** May show systolic dysfunction (reduced LVEF) or diastolic dysfunction, along with any valvular pathology.

5. Diagnostic Criteria:

The diagnosis of acute heart failure is made based on a combination of:

- **Clinical findings:** Symptoms of dyspnoea, orthopnoea, peripheral oedema, elevated JVP, and lung crackles.
- **Diagnostic tests:** Elevated BNP or NT-proBNP levels, echocardiographic findings of impaired left ventricular function, and signs of congestion on chest X-ray.

6. First-Line Therapy:

a) Acute Management:

1. **Oxygen Therapy:**
 - **Indication:** In hypoxemic patients with oxygen saturations < 90%.
 - **Goal:** To improve oxygenation and relieve respiratory distress.
2. **Intravenous Diuretics (e.g., Furosemide 20-80 mg IV):**
 - **Mechanism:** Loop diuretics reduce fluid overload by increasing urine output, relieving pulmonary and peripheral congestion.
 - **Indication:** First-line treatment for fluid overload and pulmonary oedema.
 - **Monitoring:** Monitor urine output and electrolytes, particularly potassium and renal function.
3. **Vasodilators (e.g., Glyceryl Trinitrate, IV nitro-glycerine):**
 - **Mechanism:** Reduces preload and afterload by dilating veins and arteries, improving cardiac output and reducing pulmonary congestion.
 - **Indication:** In patients with acute heart failure who are not hypotensive (SBP > 100 mmHg).

- **Goal:** To reduce afterload, improve forward flow, and reduce cardiac workload.
- 4. **Inotropes (e.g., Dobutamine, Milrinone):**
 - **Mechanism:** Increases myocardial contractility and cardiac output in patients with severe heart failure and low cardiac output.
 - **Indication:** Reserved for patients with cardiogenic shock or those unresponsive to diuretics and vasodilators.
 - **Monitoring:** Monitor for arrhythmias and blood pressure changes.

b) Cardiogenic Shock Management:

1. **Inotropes:** To improve cardiac output.
2. **Vasopressors (e.g., Norepinephrine):** Used if the patient is hypotensive and requires blood pressure support.
3. **Mechanical support:** In severe cases, **intra-aortic balloon pump (IABP)** or **extracorporeal membrane oxygenation (ECMO)** may be necessary.

7. Common Causes of Acute Heart Failure:

1. **Ischemic Heart Disease:** Myocardial infarction or ischemia leading to reduced cardiac function.
2. **Arrhythmias:** Atrial fibrillation, ventricular tachycardia, or bradyarrhythmias can precipitate heart failure by reducing cardiac output.
3. **Valvular Disease:** Acute mitral regurgitation or aortic stenosis can lead to sudden heart failure.
4. **Hypertensive Emergency:** Severely elevated blood pressure can precipitate heart failure by increasing afterload.
5. **Infection (e.g., Pneumonia):** Sepsis or respiratory infections can worsen heart failure.
6. **Noncompliance with Medications:** Particularly in patients with chronic heart failure, stopping diuretics or other heart failure medications can lead to decompensation.

8. Routine Monitoring and Long-Term Management:

1. **Fluid Status Monitoring:**
 - **Daily weight:** To monitor fluid retention or diuresis.
 - **Input/output chart:** Track fluid intake and urine output.
2. **Blood Pressure and Electrolytes:**
 - Regular monitoring of blood pressure, particularly in patients receiving vasodilators or inotropes.
 - Monitor electrolytes (sodium, potassium) and renal function, especially in patients on diuretics or inotropes.
3. **Chronic Heart Failure Medications:**
 - **ACE inhibitors or ARBs:** For afterload reduction and to improve survival in patients with systolic heart failure.
 - **Beta-blockers:** For long-term control of heart rate and blood pressure, as well as improving survival.
 - **Aldosterone antagonists (e.g., Spironolactone):** Helps to reduce fluid overload and improve outcomes in patients with reduced ejection fraction (HFrEF).
4. **Lifestyle Modifications:**
 - **Salt and fluid restriction:** To help reduce fluid retention.
 - **Smoking cessation and weight management:** To reduce overall cardiovascular risk.

- **Exercise:** Tailored to improve functional capacity and quality of life in stable heart failure patients.

9. Complications of Acute Heart Failure:

- **Pulmonary Oedema:** Can lead to severe respiratory distress and require mechanical ventilation.
- **Cardiogenic Shock:** Poor perfusion and low cardiac output lead to multi-organ failure.
- **Arrhythmias:** Ventricular arrhythmias or atrial fibrillation may complicate acute heart failure and increase mortality risk.
- **Acute Kidney Injury:** Due to poor perfusion and the use of diuretics, which can impair renal function.
- **Thromboembolism:** Increased risk of venous thromboembolism, including deep vein thrombosis (DVT) and pulmonary embolism, due to reduced mobility and stasis of blood flow, particularly in patients with dilated ventricles or low cardiac output.
- **Liver Congestion (Congestive Hepatopathy):** Chronic right-sided heart failure can lead to hepatic congestion, which may progress to liver dysfunction or cirrhosis.
- **Pleural Effusion:** Fluid accumulation in the pleural space due to increased venous pressure and fluid overload, contributing to respiratory symptoms.

10. Prognosis of Acute Heart Failure:

Acute heart failure has a high morbidity and mortality rate, particularly in patients with underlying chronic heart failure or in those presenting with cardiogenic shock. The prognosis depends on:

- **Severity of the episode:** Cardiogenic shock and severe left ventricular dysfunction carry a worse prognosis.
- **Underlying cause:** Correctable causes such as acute myocardial infarction with revascularization improve outcomes.
- **Response to treatment:** Early intervention, particularly with diuretics, vasodilators, and mechanical support (if needed), can improve short-term survival.
- **Long-term management:** Patients with well-managed chronic heart failure and appropriate lifestyle modifications tend to have a better long-term prognosis.

11. Summary of Key Points for Acute Heart Failure:

- **Acute heart failure (AHF)** is a medical emergency characterized by rapid onset of symptoms such as dyspnoea, fatigue, peripheral oedema, and pulmonary congestion.
- **Investigations:** Diagnosis is supported by clinical findings, ECG, chest X-ray, BNP/NT-proBNP levels, and echocardiography.
- **Initial treatment** focuses on oxygen therapy, diuretics to reduce fluid overload, and vasodilators for afterload reduction. In severe cases, inotropes and mechanical support may be required.
- **Long-term management** includes addressing underlying causes, optimizing heart failure medications (e.g., ACE inhibitors, beta-blockers, aldosterone antagonists), and regular monitoring of fluid status, electrolytes, and renal function.
- **Complications** include pulmonary oedema, cardiogenic shock, arrhythmias, thromboembolism, and multi-organ dysfunction.

65. Chronic Heart Failure

1. Features of Chronic Heart Failure:

Key Symptoms:

- **Dyspnoea:** Shortness of breath, especially with exertion or when lying flat (**orthopnoea**), and paroxysmal nocturnal dyspnoea (PND), where patients wake up at night gasping for air.
- **Cough:** Often worse at night and may produce pink, frothy sputum due to pulmonary congestion and oedema.
- **Wheeze:** Also referred to as "cardiac wheeze," which is due to fluid accumulation in the lungs.
- **Weight loss (cardiac cachexia):** Occurs in up to 15% of patients, although this may be masked by weight gain from oedema.

Signs:

- **Bibasal crackles:** Heard on lung auscultation, indicating pulmonary congestion.
- **Signs of right-sided heart failure:**
 - **Raised jugular venous pressure (JVP).**
 - **Peripheral oedema:** Particularly in the ankles and lower legs.
 - **Hepatomegaly:** Liver enlargement due to venous congestion.

2. Drug Management of Chronic Heart Failure (Based on 2018 NICE Guidelines):

First-Line Therapy:

1. **ACE Inhibitors (e.g., Ramipril, Enalapril):**
 - **Mechanism:** Reduces preload and afterload, improving survival and reducing hospitalizations.
 - **Note:** Should be started one drug at a time (ACE inhibitor or beta-blocker) based on clinical judgment.
2. **Beta-blockers (e.g., Bisoprolol, Carvedilol, Nebivolol):**
 - **Mechanism:** Reduces heart rate and myocardial oxygen demand, improving long-term survival.
 - **Note:** These drugs are licensed specifically for heart failure treatment in the UK.
3. **Important note for HFpEF:** Neither ACE inhibitors nor beta-blockers have been shown to improve mortality in heart failure with preserved ejection fraction (HFpEF).

Second-Line Therapy:

1. **Aldosterone Antagonists (e.g., Spironolactone, Eplerenone):**
 - **Mechanism:** Inhibits aldosterone, reducing fluid retention and fibrosis, and improving outcomes.
 - **Caution:** Monitor potassium levels, as ACE inhibitors and aldosterone antagonists both increase the risk of **hyperkalaemia**.
2. **SGLT-2 Inhibitors (e.g., Dapagliflozin, Empagliflozin, Canagliflozin):**
 - **Mechanism:** Reduces glucose reabsorption, increases urinary glucose excretion, and improves heart failure outcomes by reducing hospitalizations and cardiovascular deaths.
 - **NICE Guidance:** Dapagliflozin is recommended as an add-on to optimized standard care in HFrEF.

Third-Line Therapy (Initiated by a specialist):

1. **Ivabradine:**
 - **Indication:** Used if the patient is in sinus rhythm with a heart rate > 75 bpm and LVEF < 35%.
2. **Sacubitril-Valsartan:**

- **Indication:** Used in HFrEF patients symptomatic on ACE inhibitors or ARBs with LVEF < 35%. Requires a wash-out period after stopping ACE inhibitors or ARBs.
- 3. **Hydralazine-Nitrate Combination:**
 - **Indication:** Particularly useful in Afro-Caribbean patients.
- 4. **Digoxin:**
 - **Mechanism:** Enhances inotropy (contractility), improving symptoms but not proven to reduce mortality. Particularly beneficial in patients with coexisting atrial fibrillation.
- 5. **Cardiac Resynchronization Therapy (CRT):**
 - **Indications:** Used in patients with heart failure and a widened QRS complex (e.g., left bundle branch block) on ECG, to improve coordination of ventricular contractions.

3. Additional Treatments:

- **Annual influenza vaccination:** Reduces risk of respiratory infections, which can exacerbate heart failure.
- **Pneumococcal vaccination:** One-off vaccine for most adults, with boosters every 5 years for those with asplenia, splenic dysfunction, or chronic kidney disease.

4. Chronic Heart Failure: NYHA Classification (New York Heart Association):

1. **NYHA Class I:**
 - **Symptoms:** No symptoms, no limitations in physical activity.
2. **NYHA Class II:**
 - **Symptoms:** Mild symptoms with slight limitation of physical activity. Comfortable at rest, but ordinary activity causes fatigue or dyspnoea.
3. **NYHA Class III:**
 - **Symptoms:** Moderate symptoms with marked limitation of physical activity. Comfortable at rest, but less-than-ordinary activity causes symptoms.
4. **NYHA Class IV:**
 - **Symptoms:** Severe symptoms, with inability to perform any physical activity without discomfort. Symptoms are present even at rest.

5. Chronic Heart Failure: Diagnosis (2018 NICE Guidelines):

First-Line Investigation:

- **N-terminal pro-B-type natriuretic peptide (NT-proBNP):**
 - **Purpose:** Used for all patients with suspected heart failure as the first-line diagnostic test.

Interpreting NT-proBNP Levels:

- **High levels:**
 - **NT-proBNP > 2000 pg/ml (236 pmol/L):** Arrange specialist assessment and echocardiography within 2 weeks.
- **Raised levels:**
 - **NT-proBNP 400-2000 pg/ml (47-236 pmol/L):** Arrange specialist assessment and echocardiography within 6 weeks.

6. Serum Natriuretic Peptides (BNP/NT-proBNP):

- **B-type natriuretic peptide (BNP)** is released by the left ventricle in response to strain, and elevated levels are associated with poor prognosis in heart failure.

BNP Level	NT-proBNP Level	Interpretation
> 400 pg/ml	> 2000 pg/ml	High levels (poor prognosis)
100-400 pg/ml	400-2000 pg/ml	Raised levels
< 100 pg/ml	< 400 pg/ml	Normal levels

Factors Influencing BNP/NT-proBNP Levels:

- **Increase BNP levels:** Left ventricular hypertrophy, ischemia, tachycardia, right ventricular overload, hypoxemia (e.g., pulmonary embolism), reduced GFR, sepsis, COPD, diabetes, age > 70, and liver cirrhosis.
- **Decrease BNP levels:** Obesity, use of diuretics, ACE inhibitors, beta-blockers, ARBs, and aldosterone antagonists.

7. Summary of Key Points for Chronic Heart Failure:

- **Features:** Dyspnoea, cough, orthopnoea, PND, bibasal crackles, signs of right-sided heart failure (raised JVP, peripheral oedema, hepatomegaly).
- **Drug Management:** First-line treatment includes ACE inhibitors and beta-blockers. Second-line therapy includes aldosterone antagonists and SGLT2 inhibitors. Third-line options, initiated by specialists, include ivabradine, sacubitril-valsartan, digoxin, and CRT.
- **NYHA Classification:** Ranges from Class I (no symptoms) to Class IV (severe symptoms present at rest).
- **Diagnosis:** NT-proBNP is the first-line investigation, with echocardiography required for confirmation.

66. Hypertension

1. Detailed Definition of Hypertension:

Hypertension is one of the most common medical conditions encountered in the developed world, characterized by a persistently elevated blood pressure. While blood pressure normally varies with time of day and exertion levels, hypertension refers to chronically raised blood pressure. This condition is particularly important as it is a significant risk factor for cardiovascular diseases such as ischemic heart disease, stroke, and chronic kidney disease. Hypertension is often asymptomatic unless blood pressure is severely elevated.

Blood Pressure Classification (NICE Guidelines, 2019):

- **Normal blood pressure:** 90/60 mmHg to 140/90 mmHg.
- **Stage 1 Hypertension:**
 - Clinic BP $\geq$ 140/90 mmHg and
 - Ambulatory BP (ABPM) or home BP (HBPM) average $\geq$ 135/85 mmHg.
- **Stage 2 Hypertension:**
 - Clinic BP $\geq$ 160/100 mmHg and
 - ABPM/HBPM average $\geq$ 150/95 mmHg.
- **Severe Hypertension:**
 - Clinic systolic BP $\geq$ 180 mmHg or
 - Diastolic BP $\geq$ 120 mmHg.

2. Common Presenting Complaints and Symptoms:

Hypertension is often called the "silent killer" because it usually presents without symptoms until the blood pressure is severely elevated. However, when symptoms do occur, they may include:

- **Headaches:** More common with severely elevated BP (e.g., >200/120 mmHg).
- **Visual disturbances:** Blurred vision or loss of vision may occur due to hypertensive retinopathy.
- **Nosebleeds:** Rare but may occur in severe hypertension.
- **Fatigue:** Generalized tiredness and lethargy.
- **Dizziness or light-headedness.**
- **Seizures:** Rarely, in cases of hypertensive encephalopathy.

In **secondary hypertension**, additional symptoms may be related to the underlying cause:

- **Primary hyperaldosteronism:** Muscle weakness and frequent urination.
- **Pheochromocytoma:** Episodes of palpitations, sweating, and headaches.
- **Renal artery stenosis:** Symptoms of kidney dysfunction like flank pain or haematuria.

3. First-Line Investigations:

NICE recommends a structured approach to diagnosing hypertension and identifying possible secondary causes.

a) Blood Pressure Measurement:

- **Clinic BP Measurement:** If clinic BP is consistently $\geq 140/90$ mmHg, further testing with **ABPM** or **HBPM** is required.
 - **ABPM:** Measures BP over 24 hours to eliminate "white coat hypertension." BP $\geq 135/85$ mmHg confirms the diagnosis of hypertension.
 - **HBPM:** Similar diagnostic criteria as ABPM, requiring BP measurements over several days.

b) Blood Tests:

1. **Renal Function (Urea & Electrolytes):**
 - Purpose: Assess kidney function and exclude renal causes.
 - Explanation: Elevated creatinine or abnormal electrolytes may indicate chronic kidney disease or secondary hypertension from renal pathology.
2. **Aldosterone-to-Renin Ratio (ARR):**
 - Purpose: Screen for **primary hyperaldosteronism**.
 - Explanation: High aldosterone with low renin suggests aldosterone-producing tumours or hyperplasia.
3. **Thyroid Function Tests (TFTs):**
 - Purpose: To exclude **hyperthyroidism** or **hypothyroidism**, which can affect BP.
 - Explanation: Thyroid hormones play a role in regulating vascular tone.
4. **Lipid Profile:** To assess cardiovascular risk.
5. **HbA1c:** To check for coexisting diabetes mellitus.

c) Urinalysis:

- **Albumin**

Ratio (ACR): Detects proteinuria, which may indicate hypertensive nephropathy or secondary renal causes.

d) Imaging:

1. **Renal Ultrasound/Doppler:** To assess for **renal artery stenosis**, a common cause of secondary hypertension.
2. **Adrenal CT/MRI:** Used if **pheochromocytoma** or **primary hyperaldosteronism** is suspected.

3. **ECG:** To assess for **left ventricular hypertrophy (LVH)** or ischemic changes related to hypertensive heart disease.
4. **Echocardiogram:** May be used if there are concerns of heart failure or LVH.

4. Diagnosis Criteria:

- **Stage 1 Hypertension:**
 - Clinic BP $\geq$ 140/90 mmHg.
 - ABPM/HBPM $\geq$ 135/85 mmHg.
- **Stage 2 Hypertension:**
 - Clinic BP $\geq$ 160/100 mmHg.
 - ABPM/HBPM $\geq$ 150/95 mmHg.
- **Severe Hypertension:**
 - Clinic systolic BP $\geq$ 180 mmHg or diastolic BP $\geq$ 120 mmHg.

5. First-Line Therapy According to NICE Guidelines (2019):

a) Lifestyle Modifications:

1. **Diet:** Low-salt diet (<6 g/day), balanced diet rich in fruits and vegetables.
2. **Physical Activity:** Regular exercise (e.g., 30 minutes of moderate activity 5 days a week).
3. **Weight Management:** Aim for a healthy BMI.
4. **Smoking Cessation and Alcohol Reduction.**
5. **Reduce Caffeine Intake.**

b) Pharmacological Therapy:

1. **ACE Inhibitors (e.g., Ramipril 2.5-10 mg daily):**
 - **Mechanism:** Inhibits conversion of angiotensin I to angiotensin II, reducing vasoconstriction and BP.
 - **Contraindications:** Avoid in pregnancy and bilateral renal artery stenosis.
2. **Angiotensin II Receptor Blockers (ARBs) (e.g., Losartan 50-100 mg daily):**
 - **Mechanism:** Blocks angiotensin II receptors, reducing BP. Used if ACE inhibitors are not tolerated due to cough.
3. **Calcium Channel Blockers (e.g., Amlodipine 5-10 mg daily):**
 - **Mechanism:** Blocks calcium channels in vascular smooth muscle, reducing vascular resistance.
 - **First-line** for patients aged $\geq$ 55 or of Afro-Caribbean origin.
4. **Thiazide-Like Diuretics (e.g., Indapamide 1.5 mg daily):**
 - **Mechanism:** Inhibits sodium reabsorption in the kidneys, reducing blood volume and BP.
 - **Side Effects:** Hyponatremia, hypokalaemia.

6. Contraindications and Second-Line Therapy:

Contraindications:

1. **ACE Inhibitors/ARBs:** Avoid in pregnancy, bilateral renal artery stenosis, and hyperkalaemia.
 - **Second-line:** Use **calcium channel blockers** or **thiazide diuretics** if contraindicated.
2. **Calcium Channel Blockers:** Avoid in heart failure.
 - **Second-line:** Use **thiazide diuretics** or **beta-blockers**.

Second-Line Therapy:

- **Spironolactone (25-50 mg daily):** Aldosterone antagonist used in resistant hypertension, particularly when potassium levels are low. Monitor for **hyperkalaemia**.

7. Routine Monitoring:

1. **Blood Pressure:**
 - Regular clinic BP checks and ABPM/HBPM if necessary to monitor control.
2. **Renal Function:**
 - Regular monitoring of renal function and electrolytes, particularly for patients on ACE inhibitors, ARBs, or diuretics.
3. **Cardiovascular Risk:**
 - Monitor lipids, HbA1c, and ECG for any signs of ischemic heart disease or hypertensive complications.

8. Summary of Key Points:

- Hypertension is classified as **primary (essential)** or **secondary** based on the cause.
- Diagnosis relies on **ABPM/HBPM** to avoid "white coat hypertension."
- First-line management includes **lifestyle changes** and **pharmacological therapy**, typically with **ACE inhibitors, ARBs, calcium channel blockers, or thiazide diuretics**.
- Monitoring is essential to prevent complications and adjust treatment as needed.

67. Infective Endocarditis

1. Definition of Infective Endocarditis (IE):

Infective Endocarditis (IE) is an infection of the endocardial surface of the heart, typically involving the heart valves, but it may also affect septal defects or the mural endocardium. IE is most commonly caused by bacteria that enter the bloodstream and adhere to damaged or prosthetic valves. The infection can lead to vegetation formation, valve destruction, embolism, and systemic immune reactions. **Staphylococcus aureus** and **Streptococci** are the leading causative organisms.

2. Aetiology of Infective Endocarditis:

The strongest risk factor for developing infective endocarditis is a **previous episode of endocarditis**. Other significant risk factors include:

Risk Factors:

- **Previously normal valves** (50% of cases): Typically an acute presentation; the mitral valve is most commonly affected.
- **Rheumatic valve disease** (30%): Scarring from past rheumatic fever can predispose to endocarditis.
- **Prosthetic valves:** Increased risk of both early and late infection, especially perioperatively.
- **Congenital heart defects:** Structural abnormalities like septal defects or bicuspid aortic valves increase the risk.
- **Intravenous drug users (IVDUs):** The tricuspid valve is typically affected in these patients.
- **Other causes:** Recent body piercings, poor dental hygiene, and invasive procedures.

Causative Microorganisms:

1. **Staphylococcus aureus:**
 - Most common cause of IE, especially in acute cases and in IVDUs.
 - Frequently affects both native and prosthetic valves.

2. **Streptococcus viridans:**

- Historically the most common cause but now more prevalent in developing countries.
- Found in the mouth and dental plaque, often associated with dental procedures and poor oral hygiene.

3. **Coagulase-negative Staphylococci (e.g., Staphylococcus epidermidis):**

- Common in prosthetic valve endocarditis, typically resulting from perioperative contamination.

4. **Streptococcus bovis (Streptococcus gallolyticus):**

- Associated with colorectal cancer.

5. **Non-infective causes:**

- **Libman-Sacks endocarditis** (associated with systemic lupus erythematosus).
- **Marantic endocarditis:** Related to malignancy.

Culture-Negative Causes:

- **Prior antibiotic therapy** can make blood cultures negative.
- **Coxiella burnetii** (Q fever), **Bartonella**, **Brucella**, and the **HACEK organisms** (Haemophilus, Actinobacillus, Cardiobacterium, Eikenella, and Kingella) can also cause IE but are more difficult to culture.

3. Common Presenting Complaints and Symptoms:

IE can present with a broad spectrum of symptoms due to infection, embolic events, and immune-mediated processes. Symptoms can be acute or subacute depending on the causative organism.

General Symptoms:

- **Fever** (low-grade, persistent).
- **Malaise, fatigue, and night sweats.**
- **Weight loss.**

Cardiac Symptoms:

- **New or changing heart murmur.**
- **Shortness of breath** due to heart failure.
- **Chest pain** from coronary emboli.

Embolic Symptoms:

- **Stroke, TIA, or other embolic phenomena** (e.g., splenic or renal infarcts).
- **Pulmonary emboli** in right-sided IE.
- **Splinter haemorrhages, Janeway lesions, Osler's nodes, Roth spots.**

Immune-Mediated Symptoms:

- **Glomerulonephritis** causing haematuria and renal impairment.
- **Arthralgia and myalgia.**

4. First-Line Investigations:

Diagnosis is based on clinical features, blood cultures, and echocardiography, following the **Modified Duke Criteria** and **NICE guidelines**.

a) Blood Cultures:

- **Three sets** of blood cultures from different sites over 24 hours before starting antibiotics.
- Positive cultures identify organisms like **Staphylococcus aureus**, **Streptococcus viridans**, and **HACEK organisms**.

b) Echocardiography:

1. **Transthoracic echocardiography (TTE):** Initial test for visualizing vegetations and valve destruction.
2. **Transesophageal echocardiography (TEE):** More sensitive for detecting vegetations, abscesses, and prosthetic valve involvement.

c) Blood Tests:

- **Full Blood Count (FBC):** Leukocytosis and anaemia of chronic disease.
- **Inflammatory markers:** Elevated CRP and ESR.
- **Renal function:** Check for kidney damage (urea, creatinine).
- **Urinalysis:** Proteinuria or haematuria (suggests glomerulonephritis).

d) ECG and Imaging:

- **ECG:** Detects conduction abnormalities (e.g., prolonged PR interval).
- **Chest X-ray:** May show pulmonary emboli in right-sided IE or heart failure.

5. Diagnostic Criteria: Modified Duke Criteria

The **Modified Duke Criteria** combine clinical, microbiological, and imaging findings to diagnose IE.

Major Criteria:

1. **Positive blood cultures:**
 - Two positive cultures showing typical IE organisms (e.g., **Streptococcus viridans**, **HACEK**, **Staphylococcus aureus**).
2. **Endocardial involvement:**
 - Positive echocardiogram showing vegetations, abscesses, or new regurgitation.

Minor Criteria:

1. Predisposing heart condition or IVDU.
2. Fever $>38^{\circ}\text{C}$.
3. Vascular phenomena (emboli, **Janeway lesions**, etc.).
4. Immunological phenomena (**Osler's nodes**, **Roth spots**, glomerulonephritis).
5. Microbiological evidence not meeting major criteria.

Definitive IE requires:

- **2 major criteria**, or
- **1 major + 3 minor criteria**, or
- **5 minor criteria**.

6. First-Line Therapy According to Guidelines:

Treatment involves **prolonged intravenous antibiotics** tailored to the causative organism.

Empirical Antibiotic Therapy:

- **Native valve endocarditis:**
 - **Amoxicillin + low-dose gentamicin** (consider vancomycin if penicillin allergic or MRSA suspected).
- **Prosthetic valve endocarditis:**
 - **Vancomycin + rifampicin + low-dose gentamicin**.

Targeted Therapy:

- **Staphylococcal endocarditis:**
 - **Flucloxacillin** (add rifampicin and gentamicin for prosthetic valve).
 - If penicillin allergic or MRSA: **Vancomycin + rifampicin**.
- **Streptococcal endocarditis:**
 - **Benzylpenicillin**.
 - If penicillin allergic: **Vancomycin + gentamicin**.

7. Infective Endocarditis: Prophylaxis

The **NICE 2008 guidelines** recommend **no routine antibiotic prophylaxis** for most procedures, including:

- Dental procedures.
- Gastrointestinal and genitourinary tract procedures.
- Respiratory procedures, including bronchoscopy.

However, **American Heart Association** and **European Society of Cardiology** guidelines still recommend prophylaxis for high-risk patients undergoing dental procedures.

8. Prognosis and Management

Poor Prognostic Factors:

- **Staphylococcus aureus** infection.
- **Prosthetic valve infection** (especially early post-surgery).
- **Culture-negative endocarditis**.
- **Low complement levels**.

Mortality Rates:

- **Staphylococci**: ~30%.
- **Bowel organisms (e.g., Streptococcus bovis)**: ~15%.
- **Streptococci**: ~5%.

Surgical Indications:

- Severe valve dysfunction causing heart failure.
- **Aortic abscess** (indicated by a prolonged PR interval).
- Persistent infection despite antibiotics.
- Recurrent embolic events.
- Fungal infections or infections resistant to antibiotics.

9. Routine Monitoring:

1. **Blood cultures**: Repeated to assess the clearance of bacteraemia.
2. **Renal function**: Monitor for nephrotoxicity, especially in patients on gentamicin.
3. **Echocardiogram**: Follow-up imaging to monitor resolution of vegetations and assess valve function.
4. **Clinical monitoring**: Check for signs of heart failure, embolic events, or neurological complications.

10. Summary of Key Points:

- **Infective Endocarditis** is an infection of the heart valves or endocardium, often caused by **Staphylococcus aureus** or **Streptococci**.
- Diagnosis is based on the **Modified Duke Criteria**, combining clinical features, blood cultures, and echocardiographic evidence.
- **Empirical antibiotics** are guided by the patient's clinical status, with surgery considered for severe cases.
- **Prophylaxis** is generally not recommended for most procedures (according to **NICE**), but guidelines differ globally.

68. Pericardial Disease

1. Definition of Pericardial Disease:

Pericardial disease encompasses a range of conditions that affect the pericardium, the double-layered sac surrounding the heart. These conditions include **acute pericarditis**, **pericardial effusion**, **cardiac tamponade**, and **constrictive pericarditis**. The pericardium helps to stabilize the heart and reduce friction during cardiac movement. Inflammation, fluid accumulation, or structural changes in the pericardium can lead to a variety of clinical symptoms.

2. Types of Pericardial Disease:

a) Acute Pericarditis:

Acute pericarditis refers to inflammation of the pericardium lasting less than 4-6 weeks. It can be caused by infections, systemic diseases, or trauma.

- **Aetiology:**

- **Viral infections:** Coxsackievirus, echovirus, and others.
- **Tuberculosis.**
- **Uraemia.**
- **Post-myocardial infarction (MI):**
 - **Early (1-3 days):** Fibrinous pericarditis.
 - **Late (weeks to months):** Autoimmune pericarditis (Dressler's syndrome).
- **Radiotherapy.**
- **Connective tissue diseases:** Systemic lupus erythematosus (SLE), rheumatoid arthritis.
- **Hypothyroidism.**
- **Malignancy:** Lung cancer, breast cancer.
- **Trauma.**

- **Features:**

- **Pleuritic chest pain:** Sharp and worsens with inspiration. It is relieved by sitting up and leaning forward.
- **Other symptoms:** Non-productive cough, dyspnoea, and flu-like symptoms.
- **Pericardial rub:** A scratchy sound heard on auscultation over the left sternal border.

- **Investigations:**

1. **ECG:**

- Diffuse, global **saddle-shaped ST elevation**.
- **PR depression** (most specific ECG marker for pericarditis).

2. **Transthoracic echocardiography:** Recommended for all patients with suspected pericarditis to assess for effusion.

3. **Blood tests:**

- **Inflammatory markers:** Elevated CRP and ESR.
- **Troponin:** Elevated in about 30% of cases, indicating possible myopericarditis.

- **Management:**

- Most cases can be managed on an outpatient basis.
- **High-risk features** (fever > 38°C, elevated troponin) require inpatient care.
- Treat any underlying cause (e.g., tuberculosis, uraemia).
- **NSAIDs and colchicine** are first-line treatments for acute idiopathic or viral pericarditis:
 - **Ibuprofen** 400–600 mg every 6–8 hours or **Aspirin** 2–4 g daily.

- **Colchicine** 0.5 mg twice daily for 3 months.
- Strenuous activity should be avoided until symptom resolution and normalization of inflammatory markers (1-2 weeks).
- The dose of NSAIDs should be tapered gradually over time.

b) Pericardial Effusion:

Accumulation of fluid within the pericardial sac due to pericarditis, infection, trauma, malignancy, or renal failure.

- **Symptoms:**
 - Often asymptomatic if the accumulation is slow.
 - Symptoms include **dyspnoea**, **chest fullness**, and **muffled heart sounds** on auscultation.
- **Investigations:**
 1. **Echocardiography:** Gold standard for detecting effusion.
 2. **Chest X-ray:** Enlarged cardiac silhouette ("water bottle" appearance).
 3. **ECG:** Low-voltage QRS complexes, **electrical alternans** (alternating QRS amplitude due to heart swinging in fluid).
- **Management:**
 - **Small effusions:** Observation and serial echocardiography.
 - **Large effusions or tamponade:** **Pericardiocentesis** is required to drain the fluid.

c) Cardiac Tamponade:

A life-threatening complication of pericardial effusion, where the pressure from the fluid prevents the heart from filling properly, reducing cardiac output.

- **Symptoms:**
 - **Beck's triad:**
 1. **Hypotension.**
 2. **Muffled heart sounds.**
 3. **Raised jugular venous pressure (JVP).**
 - **Tachycardia, pulsus paradoxus** (a drop in systolic BP > 10 mmHg during inspiration).
 - **Dyspnoea, fatigue, shock, and altered consciousness.**
- **Investigations:**
 1. **Echocardiography:** Confirms large pericardial effusion and diastolic collapse of the right atrium or ventricle.
 2. **ECG:** Low voltage QRS complexes, **electrical alternans.**
 3. **Chest X-ray:** Enlarged cardiac silhouette.
- **Management:**
 - **Urgent pericardiocentesis** to relieve pressure on the heart.
 - IV fluids to maintain BP until pericardiocentesis.

d) Constrictive Pericarditis:

A chronic condition where the pericardium becomes thickened and fibrotic, restricting the heart's ability to expand and fill properly.

- **Aetiology:**
 - Any cause of pericarditis can lead to constrictive pericarditis, especially **tuberculosis.**
- **Features:**
 - **Dyspnoea and fatigue.**

- **Right heart failure signs:** Elevated JVP, ascites, peripheral oedema, hepatomegaly.
- **Kussmaul's sign:** Paradoxical rise in JVP during inspiration.
- **Pericardial knock:** Loud early diastolic sound (S3) due to abrupt cessation of ventricular filling.
- **Investigations:**
 1. **Echocardiography:** Shows a thickened pericardium and restricted ventricular filling.
 2. **CT/MRI:** To assess pericardial thickening and calcification.
 3. **CXR:** Shows pericardial calcification.
- **Management:**
 - **Diuretics:** To reduce fluid overload.
 - **Surgical pericardiectomy:** Definitive treatment for severe cases.

3. Key Differences Between Cardiac Tamponade and Constrictive Pericarditis:

Feature	Cardiac Tamponade	Constrictive Pericarditis
JVP	Absent Y descent	X and Y descent present
Pulsus paradoxus	Present	Absent
Kussmaul's sign	Rare	Present
CXR	Normal or enlarged heart	Pericardial calcification

4. First-Line Investigations:

1. **ECG:**
 - **Pericarditis:** Diffuse ST elevation, PR depression.
 - **Tamponade:** Low-voltage QRS complexes, electrical alternans.
2. **Echocardiography:**
 - Essential for assessing **effusion**, **tamponade**, and **constrictive pericarditis**.
3. **Chest X-ray:**
 - Enlarged cardiac silhouette in effusion, pericardial calcification in constrictive pericarditis.
4. **Blood tests:**
 - Elevated **CRP**, **ESR** in pericarditis.
 - **Troponin** elevated in myopericarditis.
5. **CT/MRI:**
 - Useful in diagnosing **constrictive pericarditis**.

5. Management Summary:

- **Acute Pericarditis:**
 - NSAIDs (e.g., **ibuprofen** 400-600 mg every 6–8 hours).
 - **Colchicine** 0.5 mg twice daily for 3 months.
 - In severe cases, **corticosteroids** may be needed.
- **Pericardial Effusion:**
 - Small: Observation and serial echocardiography.
 - Large or tamponade: **Pericardiocentesis**.
- **Cardiac Tamponade:**
 - Emergency **pericardiocentesis**.
 - IV fluids to support blood pressure.
- **Constrictive Pericarditis:**
 - **Diuretics** for symptom relief.

- **Pericardiectomy** for severe cases.

6. Prognosis and Follow-Up:

- **Echocardiography:** Serial monitoring for pericardial effusion and tamponade resolution.
- **ECG:** Monitoring of ST and PR changes in pericarditis.
- **Blood tests:** Monitoring inflammatory markers and troponin levels.
- **Physical exam:** Regular assessments for signs of recurrence or constriction.

69. Cardiac Tamponade

1. Definition of Cardiac Tamponade:

Cardiac tamponade is a medical emergency characterized by the accumulation of fluid in the pericardial sac under pressure. This pressure compresses the heart, particularly the right ventricle, impeding its ability to fill properly during diastole. The result is decreased cardiac output and poor tissue perfusion, which can lead to shock and death if not treated promptly.

2. Aetiology of Cardiac Tamponade:

Cardiac tamponade can be caused by any condition that leads to the rapid accumulation of fluid, blood, or pus in the pericardial sac.

- **Pericardial effusion causes:**
 - **Pericarditis** (viral, bacterial, autoimmune).
 - **Trauma** (e.g., blunt or penetrating chest injury, iatrogenic after procedures).
 - **Malignancy** (e.g., metastatic lung or breast cancer).
 - **Uraemia** (chronic kidney disease).
 - **Aortic dissection** (blood leaking into the pericardium).
 - **Post-myocardial infarction** (ventricular rupture causing hemopericardium).

3. Pathophysiology:

In **cardiac tamponade**, the accumulation of pericardial fluid increases the pressure on the heart, particularly the right side. As the pressure in the pericardium rises above the intracardiac pressure, it prevents the heart from filling properly, leading to reduced stroke volume and decreased cardiac output.

4. Clinical Features of Cardiac Tamponade:

Classical Features - Beck's Triad:

1. **Hypotension:** Due to reduced cardiac output.
2. **Raised jugular venous pressure (JVP):** From impaired venous return.
3. **Muffled heart sounds:** Due to the insulation of the heart by pericardial fluid.

Other Features:

- **Dyspnoea:** Due to pulmonary congestion and reduced cardiac output.
- **Tachycardia:** A compensatory mechanism to maintain cardiac output.
- **Absent Y descent on JVP:** Reflects limited right ventricular filling during diastole.
- **Pulsus paradoxus:** An abnormally large drop in systolic blood pressure (>10 mmHg) during inspiration, which reflects increased ventricular interdependence due to pericardial pressure.
- **Kussmaul's sign:** This is rare in tamponade (usually seen in constrictive pericarditis), and debate exists regarding its presence in tamponade.

5. ECG Findings in Cardiac Tamponade:

- **Low-voltage QRS complexes:** Caused by the insulating effect of pericardial fluid.
- **Electrical alternans:** Alternating QRS amplitude due to the heart "swinging" in the fluid-filled pericardium.

6. Investigations:

a) Echocardiography:

- **Key diagnostic tool** for tamponade, showing:
 - **Large pericardial effusion.**
 - **Diastolic collapse of the right atrium and right ventricle.**
 - Respiratory variation in mitral and tricuspid inflow velocities.

b) Chest X-ray:

- **Enlarged cardiac silhouette** ("water bottle" appearance) in large effusions.

c) Hemodynamic Monitoring:

- **Right atrial and ventricular pressures** are elevated, with equalization of diastolic pressures.

7. Key Differences Between Cardiac Tamponade and Constrictive Pericarditis:

Feature	Cardiac Tamponade	Constrictive Pericarditis
JVP	Absent Y descent	X and Y descent present
Pulsus paradoxus	Present	Absent
Kussmaul's sign	Rare	Present
Characteristic features	None	Pericardial calcification on CXR

Mnemonic for Cardiac Tamponade:

To remember the **absent Y descent** in cardiac tamponade, use the mnemonic: **TAMponade = TAMpaX**.

8. Diagnosis:

Diagnosis of cardiac tamponade is based on clinical findings, echocardiographic confirmation, and hemodynamic monitoring. **Beck's triad** and **pulsus paradoxus** are classic features, and **echocardiography** is critical for diagnosis and assessment.

9. Management of Cardiac Tamponade:

Cardiac tamponade is a medical emergency and requires urgent intervention.

a) Immediate Stabilization:

- **IV fluid resuscitation:** Temporarily increases preload to maintain cardiac output.
- **Oxygen therapy:** Ensures adequate tissue oxygenation.

b) Definitive Treatment: Urgent Pericardiocentesis:

- **Pericardiocentesis** is the gold standard and life-saving procedure for tamponade. It involves the drainage of fluid from the pericardial sac under echocardiographic or fluoroscopic guidance.
 - **Indication:** Hemodynamically unstable patients or those with confirmed tamponade on echocardiography.
 - **Procedure:** Performed using a needle inserted into the pericardial space (typically via the subxiphoid approach) to relieve the pressure on the heart.

c) Surgical Pericardial Window:

- In cases of recurrent tamponade or when loculated effusions are present, a **surgical pericardial window** may be created to allow continuous drainage of fluid into the pleural or abdominal cavity.

d) Treating the Underlying Cause:

- **Antibiotics:** If bacterial infection is suspected.
- **Dialysis:** For uremic pericarditis.
- **Chemotherapy or radiation therapy:** If tamponade is caused by malignancy.

10. Prognosis:

- **Prognosis** is good if tamponade is treated promptly, with rapid resolution of symptoms following pericardiocentesis.
- **Malignancy-related tamponade** may have a poorer prognosis depending on the stage of the underlying disease.
- Delayed treatment can lead to **shock, multi-organ failure, and death**.

Summary of Key Points for Cardiac Tamponade:

- **Cardiac tamponade** results from fluid accumulation under pressure in the pericardium, compressing the heart and limiting cardiac filling.
- **Beck's triad** (hypotension, raised JVP, and muffled heart sounds) and **pulsus paradoxus** are classic features.
- **Echocardiography** is essential for diagnosis and guides the need for **urgent pericardiocentesis**, the definitive treatment.
- Early recognition and treatment are critical to prevent hemodynamic collapse and death.

70. Acute Pericarditis

1. Definition of Acute Pericarditis:

Acute pericarditis refers to inflammation of the pericardium (the thin sac surrounding the heart), which typically lasts less than 4-6 weeks. The condition is characterized by sharp chest pain, pericardial friction rub, and characteristic ECG changes. Pericarditis may occur as an isolated condition or in association with systemic diseases or infections.

2. Aetiology of Acute Pericarditis:

Acute pericarditis can be caused by a wide range of infectious and non-infectious factors:

Infectious Causes:

- **Viral:** Coxsackievirus, echovirus (most common cause).
- **Bacterial:** Tuberculosis (TB), streptococcal infections.
- **Fungal and parasitic infections:** Rare but possible.

Non-Infectious Causes:

- **Post-myocardial infarction (MI):**
 - **Early pericarditis:** Occurs within 1-3 days after MI (fibrinous pericarditis).
 - **Late pericarditis (Dressler's syndrome):** Occurs weeks to months after MI and is thought to be immune-mediated.
- **Autoimmune diseases:** Systemic lupus erythematosus (SLE), rheumatoid arthritis.
- **Uraemia:** Seen in patients with chronic kidney disease.
- **Trauma:** Blunt or penetrating chest trauma, including post-surgical pericarditis.
- **Radiotherapy:** Damage to the pericardium due to radiation therapy.
- **Malignancy:** Lung cancer, breast cancer, or metastases to the pericardium.

- **Hypothyroidism.**

3. Clinical Features of Acute Pericarditis:

Key Symptoms:

- **Pleuritic chest pain:**
 - **Sharp and stabbing** pain that is worsened by deep inspiration or lying flat.
 - The pain is often **relieved by sitting forward**.
- **Other symptoms:**
 - Non-productive cough.
 - Dyspnoea.
 - Low-grade fever.
 - Fatigue or flu-like symptoms.

Key Signs:

- **Pericardial friction rub:**
 - A scratchy or squeaky sound heard on auscultation, often at the left lower sternal border.
 - It is a key diagnostic feature but may be transient.

4. Investigations:

a) Electrocardiogram (ECG):

- The most important investigation in diagnosing pericarditis.
- **Key ECG findings:**
 - **Diffuse ST elevation:** Typically concave or "saddle-shaped" and seen in multiple leads.
 - **PR depression:** The most specific ECG marker for pericarditis.
 - **No reciprocal ST depression**, which helps to differentiate pericarditis from myocardial infarction.

b) Echocardiography:

- Used to assess for the presence of a **pericardial effusion**, which may complicate pericarditis.
- **Transthoracic echocardiography (TTE)** is recommended for all patients with suspected pericarditis.

c) Blood Tests:

- **Inflammatory markers:**
 - **C-reactive protein (CRP)** and **erythrocyte sedimentation rate (ESR)** are typically elevated, indicating inflammation.
- **Troponin:**
 - Elevated in approximately 30% of patients, suggesting **myopericarditis** (involvement of the myocardium).
- **Renal function:**
 - To assess for uraemia in patients with kidney disease.

5. Diagnosis:

The diagnosis of acute pericarditis is based on the presence of at least two of the following four criteria:

1. **Pleuritic chest pain** (typically relieved by sitting forward).
2. **Pericardial friction rubs** on auscultation.
3. **ECG changes** (diffuse ST elevation, PR depression).

4. **New or worsening pericardial effusion** on echocardiography.

6. Management of Acute Pericarditis:

a) Outpatient vs. Inpatient Management:

- **Outpatient management** is appropriate for most patients, especially if they have no high-risk features.
- **Inpatient management** is necessary for patients with high-risk features, such as:
 - Fever > 38°C.
 - Elevated troponin (suggesting myopericarditis).
 - Large pericardial effusion or tamponade.
 - Immunocompromised state.

b) First-Line Therapy:

1. **Nonsteroidal anti-inflammatory drugs (NSAIDs):**
 - **Ibuprofen** 400–600 mg every 6–8 hours or **Aspirin** 2–4 g daily.
 - Mechanism: Reduces inflammation and relieves pain.
 - **Duration:** Continue for 1–2 weeks, followed by a gradual taper over 1–2 weeks.
2. **Colchicine:**
 - **0.5 mg twice daily** for 3 months.
 - Mechanism: Reduces inflammation and significantly lowers the recurrence rate of pericarditis.
3. **Corticosteroids:**
 - **Prednisolone** may be used in patients who cannot tolerate NSAIDs (e.g., due to peptic ulcers) or in recurrent pericarditis.
 - Should be used with caution due to the risk of recurrence after tapering.

c) Avoidance of Physical Activity:

- Patients with acute pericarditis should **avoid strenuous physical activity** until symptom resolution and normalization of inflammatory markers, typically 1–2 weeks.

d) Treatment of the Underlying Cause:

- If an identifiable cause such as bacterial infection, autoimmune disease, or uraemia is present, specific treatment for the underlying condition is required (e.g., antibiotics, dialysis, or immunosuppressive therapy).

7. Complications:

- **Pericardial effusion:** Accumulation of fluid in the pericardial sac, which can progress to cardiac tamponade in severe cases.
- **Cardiac tamponade:** Life-threatening complication where fluid under pressure compresses the heart, reducing cardiac output.
- **Constrictive pericarditis:** Chronic scarring and thickening of the pericardium, leading to impaired heart function. This may develop after recurrent episodes of pericarditis.

8. Prognosis:

- **Acute viral or idiopathic pericarditis** generally has a good prognosis, with most patients recovering within 1–2 weeks.
- **Recurrent pericarditis** can occur in 15–30% of cases but is often well-managed with colchicine and NSAIDs.
- Prognosis depends on the underlying cause, with more severe outcomes seen in patients with malignancy, tuberculosis, or autoimmune diseases.

Summary of Key Points for Acute Pericarditis:

- **Acute pericarditis** is an inflammation of the pericardial sac, most commonly caused by viral infections, autoimmune conditions, and post-myocardial infarction.
- **Pleuritic chest pain, pericardial friction rub, and saddle-shaped ST elevation** on ECG are hallmark features.
- Diagnosis requires at least two of four key criteria, and **echocardiography** is recommended to assess for pericardial effusion.
- **NSAIDs** and **colchicine** are first-line treatments, with corticosteroids reserved for refractory cases.
- Complications include **pericardial effusion, cardiac tamponade, and constrictive pericarditis**.

71. Pericardial Effusion

1. Definition of Pericardial Effusion:

Pericardial effusion refers to the accumulation of excess fluid in the pericardial cavity, the space between the two layers of the pericardium. This condition may be asymptomatic or can lead to **cardiac tamponade**, a life-threatening situation if the fluid accumulation rapidly increases the pressure on the heart.

2. Aetiology of Pericardial Effusion:

Pericardial effusion can arise from a variety of causes, broadly classified into infectious, non-infectious, and other systemic conditions:

Infectious Causes:

- **Viral infections:** Coxsackievirus, echovirus, HIV.
- **Bacterial infections:** Tuberculosis, pneumococcus, streptococcus.
- **Fungal infections:** Histoplasmosis (rare).
- **Parasitic infections:** Rare, but can be seen in some geographic areas.

Non-Infectious Causes:

- **Post-myocardial infarction (MI):**
 - Early post-MI effusion.
 - **Dressler's syndrome** (autoimmune pericarditis occurring weeks after MI).
- **Uraemia:** Seen in patients with chronic kidney disease.
- **Trauma:** Penetrating or blunt chest trauma, including post-cardiac surgery.
- **Malignancy:** Lung cancer, breast cancer, lymphoma, or metastases.
- **Autoimmune diseases:** Systemic lupus erythematosus (SLE), rheumatoid arthritis.
- **Radiotherapy:** Following chest irradiation.
- **Hypothyroidism:** Can cause mild to moderate effusion.

3. Pathophysiology of Pericardial Effusion:

In pericardial effusion, the pericardial sac fills with fluid beyond its normal physiological volume (15–50 mL). Depending on the **rate** of accumulation and the **total volume** of fluid, the pericardium may stretch, or it may not, leading to increased intrapericardial pressure. If the pressure rises rapidly or if there is a large amount of fluid, the heart becomes compressed, leading to impaired filling and reduced cardiac output, which can evolve into **cardiac tamponade**.

4. Clinical Features of Pericardial Effusion:

Symptoms of pericardial effusion depend on the size, rate of accumulation, and whether cardiac tamponade develops.

Small, Slow-Accumulating Effusions:

- **Often asymptomatic**, especially if the fluid accumulation is gradual.
- **Mild chest discomfort** or a sense of fullness in the chest.
- **Dyspnoea** on exertion.

Large or Rapidly Accumulating Effusions:

- **Severe dyspnoea.**
- **Chest pain:** Pressure-like or discomfort.
- **Fatigue, light-headedness, or dizziness** due to reduced cardiac output.
- **Muffled heart sounds** on auscultation.

Signs of Cardiac Tamponade (Severe Complication):

- **Hypotension, tachycardia, and raised jugular venous pressure (JVP).**
- **Pulsus paradoxus** (exaggerated drop in blood pressure during inspiration).
- **Beck's triad:** Hypotension, muffled heart sounds, and raised JVP.

5. Investigations:

a) Echocardiography:

- **Gold standard** for diagnosing pericardial effusion.
- Can detect the **size** and **location** of the effusion, and can identify the presence of **cardiac tamponade**.
 - **Small effusion:** Fluid < 10 mm on imaging.
 - **Moderate effusion:** Fluid 10-20 mm.
 - **Large effusion:** Fluid > 20 mm.

b) Chest X-ray:

- **Enlarged cardiac silhouette** ("water bottle" appearance) if the effusion is large.

c) Electrocardiogram (ECG):

- **Low-voltage QRS complexes:** Seen in large effusions due to the insulating effect of fluid.
- **Electrical alternans:** Alternating QRS amplitude, indicating a "swinging" heart within the fluid-filled pericardium.

d) Blood Tests:

- **Inflammatory markers:** Elevated CRP and ESR may indicate pericarditis.
- **Renal function:** Assessed for uraemia.
- **Autoimmune markers:** ANA and rheumatoid factor for suspected autoimmune causes.
- **Tumor markers:** May be tested if malignancy is suspected.

e) Pericardiocentesis with Fluid Analysis:

- Performed if the cause of the effusion is unclear.
- **Fluid analysis:**
 - **Cytology:** To look for malignant cells.
 - **Gram stain/culture:** To identify infectious causes.
 - **Protein and glucose levels:** Helps differentiate between exudative and transudative effusions.

6. Management of Pericardial Effusion:

a) Observation:

- **Small, asymptomatic effusions** may only require observation and regular follow-up with serial echocardiography.

b) Treating the Underlying Cause:

- **Infection:** Appropriate antibiotics for bacterial causes, antifungals for fungal infections, etc.
- **Uraemia:** Dialysis may be required.
- **Autoimmune diseases:** Corticosteroids or immunosuppressive therapy may be indicated for conditions like SLE.
- **Malignancy:** Chemotherapy or radiation therapy for malignant effusions.

c) Pericardiocentesis:

- **Indications:**
 - **Large symptomatic effusions** or any effusion causing **cardiac tamponade**.
 - Performed under echocardiographic or fluoroscopic guidance to drain fluid from the pericardial sac.
- **Procedure:** Needle insertion into the pericardium to aspirate the fluid.

d) Surgical Pericardial Window:

- If the effusion is recurrent or loculated, a **surgical pericardial window** may be created to allow continuous drainage into the pleural or abdominal cavity.

e) Management of Cardiac Tamponade:

- **Urgent pericardiocentesis** is required for patients with cardiac tamponade.
- IV fluids may be given as a temporizing measure to increase preload and maintain cardiac output until the fluid can be drained.

7. Complications of Pericardial Effusion:

1. Cardiac Tamponade:

- A life-threatening complication where fluid accumulation causes pressure on the heart, restricting ventricular filling, leading to a rapid decline in cardiac output.

2. Constrictive Pericarditis:

- Chronic scarring and thickening of the pericardium following repeated or untreated pericardial effusions, leading to restricted heart function.

8. Prognosis:

- Prognosis depends on the **underlying cause** of the pericardial effusion. Effusions caused by viral infections or idiopathic pericarditis usually resolve with treatment and have a good prognosis.
- **Malignant effusions** or those due to chronic conditions like tuberculosis or autoimmune disease have a poorer prognosis.
- Timely intervention with **pericardiocentesis** for cardiac tamponade significantly improves outcomes.

Summary of Key Points for Pericardial Effusion:

- **Pericardial effusion** is the accumulation of excess fluid in the pericardial sac. Causes include infections, trauma, malignancy, uraemia, and autoimmune diseases.
- Symptoms range from asymptomatic to dyspnoea and chest discomfort, with severe cases leading to **cardiac tamponade**.
- **Echocardiography** is the gold standard for diagnosis, while **ECG** and **chest X-ray** can provide additional clues.
- Management includes **observation** for small effusions, **pericardiocentesis** for symptomatic or large effusions, and treating the **underlying cause**.

- **Cardiac tamponade** requires urgent intervention with pericardiocentesis.

72. Constrictive Pericarditis

1. Detailed Definition of Constrictive Pericarditis:

Constrictive pericarditis is a chronic condition where the pericardium (the sac surrounding the heart) becomes thickened, fibrotic, and less elastic. This leads to restricted diastolic filling of the heart, causing increased venous pressures and reduced cardiac output. Over time, this can result in symptoms of heart failure, particularly right-sided heart failure, as the heart's ability to expand and fill during diastole is limited.

2. Common Presenting Complaints and Symptoms:

Patients with constrictive pericarditis typically present with symptoms related to impaired cardiac filling and right heart failure. The progression of symptoms is usually gradual and chronic.

Symptoms:

- **Dyspnoea:** Shortness of breath, especially on exertion.
- **Fatigue:** Generalized weakness due to reduced cardiac output.
- **Peripheral oedema:** Swelling of the legs and ankles, secondary to right heart failure.
- **Ascites:** Accumulation of fluid in the abdomen.
- **Weight loss:** Cardiac cachexia may develop in advanced cases.
- **Orthopnoea:** Shortness of breath when lying flat.
- **Abdominal pain:** Due to liver congestion and hepatomegaly.

Signs:

- **Elevated jugular venous pressure (JVP)** with **prominent x and y descents**.
- **Kussmaul's sign:** Paradoxical increase in JVP during inspiration.
- **Pericardial knock:** An early diastolic sound similar to an S3 gallop.
- **Hepatomegaly:** Enlarged liver due to venous congestion.
- **Pulsus paradoxus:** Usually absent in constrictive pericarditis.

3. First-Line Investigations:

a) Blood Tests:

- **Complete blood count (CBC):** To rule out infection and check for anaemia.
- **C-reactive protein (CRP) and Erythrocyte Sedimentation Rate (ESR):** Inflammatory markers may be elevated in acute phases of pericarditis or associated conditions.
- **Renal function (urea, creatinine):** To assess for kidney involvement or concurrent uraemia.
- **Liver function tests (LFTs):** Elevated due to hepatic congestion (congestive hepatopathy).
- **Natriuretic peptides (BNP/NT-proBNP):** Can be elevated due to cardiac failure.

b) Imaging:

1. Echocardiography:

- **Thickened pericardium.**
- Signs of **septal bounce** or "shuddering" of the interventricular septum, which is a key feature.
- **Restricted ventricular filling**, with preserved ejection fraction.

2. Chest X-ray:

- May show **pericardial calcification**, particularly in cases of tuberculous constrictive pericarditis.

- Enlarged cardiac silhouette is uncommon.
- 3. **CT/MRI:**
 - **CT or MRI** can more clearly show **pericardial thickening (> 4 mm)**, a key feature of constrictive pericarditis.
 - These imaging modalities help differentiate between constrictive pericarditis and restrictive cardiomyopathy.
- 4. **Cardiac Catheterization:**
 - **Equalization of diastolic pressures** in all cardiac chambers.
 - Shows a characteristic "square root sign" or "dip and plateau" in the ventricular pressure tracings, reflecting restricted ventricular filling during diastole.

c) Hemodynamic Studies:

- **Kussmaul's sign:** An increase in JVP with inspiration, indicating poor right heart compliance.

4. Diagnosis Criteria:

Diagnosis is based on a combination of clinical presentation, imaging findings, and hemodynamic measurements. Key criteria include:

- **Pericardial thickening** (>4 mm on CT or MRI).
- **Diastolic dysfunction** with preserved systolic function.
- **Equalization of diastolic pressures** across all cardiac chambers.
- **Septal bounce** or shuddering seen on echocardiography or cardiac MRI.
- **JVP waveform** showing a prominent Y descent.

Reference ranges:

- **Pericardial thickness:** >4 mm is suggestive of constrictive pericarditis.
- **Hemodynamic findings:** Square root sign in ventricular pressure tracing during catheterization.

5. First-Line Therapy According to Guidelines:

a) Medical Management:

Medical therapy is often supportive while preparing for definitive surgical intervention.

1. Diuretics:

- **Furosemide:** 20-80 mg daily, titrated to relieve symptoms of fluid overload (oedema, ascites).
- **Mechanism of action:** Reduces blood volume and venous pressure, relieving symptoms of right-sided heart failure.
- **Indication:** Used to manage fluid overload and congestive symptoms.

b) Contraindications to First-Line Therapy:

- Diuretics should be used cautiously in patients with **low blood pressure** or **pre-renal failure** due to the risk of worsening renal function.

c) Second-Line Therapy:

- **Sodium restriction:** Dietary sodium reduction to <2 g/day can enhance the effectiveness of diuretics.
- **Other diuretics:**
 - **Spironolactone** (25-50 mg daily) may be used as an adjunct to manage fluid retention, especially if potassium levels are normal.

d) Definitive Treatment:

- **Pericardiectomy:** Surgical removal of the thickened pericardium is the **definitive treatment** for constrictive pericarditis. It is indicated in patients with severe symptoms

or refractory heart failure. This procedure offers the potential for a cure, but carries significant risk.

6. Routine Monitoring:

- **Echocardiography:** Periodic assessment to monitor heart function and progression of the disease.
- **Blood tests:** Regular monitoring of electrolytes and renal function, especially in patients on diuretics.
- **Liver function:** Periodically monitored in patients with significant right heart failure, as hepatic congestion can worsen liver function over time.
- **Diuretic efficacy:** Assess daily weight and symptom relief to adjust diuretic doses appropriately.

Summary of Key Points for Constrictive Pericarditis:

- **Constrictive pericarditis** results from the fibrotic thickening of the pericardium, leading to restricted diastolic filling of the heart and symptoms of right-sided heart failure.
- **Symptoms** include dyspnoea, peripheral oedema, and ascites, with **Kussmaul's sign** and a **pericardial knock** on physical examination.
- **First-line investigations** include echocardiography, CT/MRI, and cardiac catheterization, with pericardial thickening and the characteristic "square root sign" seen on pressure tracings.
- **Diuretics** are used as a first-line treatment for symptom management, but **pericardiectomy** is the definitive treatment.
- Regular **monitoring** of renal and liver function, as well as echocardiographic findings, is important for patients on diuretic therapy and awaiting surgery.

73. Aortic Valve Disease

1. Detailed Definition of Aortic Valve Disease:

Aortic valve disease refers to any dysfunction of the aortic valve, which can lead to either **aortic stenosis (AS)** or **aortic regurgitation (AR)**. Both conditions affect the flow of blood from the left ventricle into the aorta and can result in impaired cardiac output, symptoms of heart failure, and other complications. Aortic stenosis is characterized by a narrowed aortic valve, while aortic regurgitation results from a leaky valve, causing backflow of blood into the left ventricle.

2. Common Presenting Complaints and Symptoms:

Aortic Stenosis (AS):

- **Dyspnoea:** Shortness of breath, especially on exertion, is common due to increased left ventricular pressure.
- **Angina:** Chest pain due to reduced coronary blood flow.
- **Syncope:** Fainting spells, particularly with exertion, due to fixed cardiac output.
- **Fatigue:** Generalized weakness from reduced cardiac output.

Aortic Regurgitation (AR):

- **Dyspnoea:** Progressive shortness of breath, initially with exertion and later at rest.
- **Palpitations:** Due to increased stroke volume and hyperdynamic circulation.
- **Orthopnoea and paroxysmal nocturnal dyspnoea:** Due to heart failure.
- **Fatigue:** As left ventricular function worsens.

Signs of Aortic Valve Disease:

- **Aortic stenosis:**
 - **Ejection systolic murmur** heard loudest at the right second intercostal space, radiating to the carotids.
 - **Narrow pulse pressure.**
 - **Slow-rising and weak carotid pulse** ("pulsus parvus et tardus").
- **Aortic regurgitation:**
 - **Early diastolic murmur** heard best at the left sternal edge.
 - **Wide pulse pressure.**
 - **Water-hammer pulse** (rapid rise and fall of the pulse).
 - **Quincke's sign:** Visible pulsations in the nail bed.
 - **Corrigan's sign:** Visible pulsations of the carotid artery.

3. First-Line Investigations:

a) Echocardiography:

- **Gold standard** for diagnosing aortic valve disease.
- Provides information about valve anatomy, the severity of stenosis or regurgitation, and left ventricular function.

b) Electrocardiogram (ECG):

- **Aortic stenosis:** Shows signs of left ventricular hypertrophy (LVH), such as tall R waves in left-sided leads (V5 and V6).
- **Aortic regurgitation:** May also show signs of LVH due to chronic volume overload.

c) Chest X-ray:

- **Aortic stenosis:** May show post-stenotic dilation of the aorta or calcification of the aortic valve.
- **Aortic regurgitation:** May show cardiomegaly (enlarged heart) due to left ventricular enlargement.

d) Blood Tests:

- **Brain natriuretic peptide (BNP):** Raised BNP levels may indicate heart failure secondary to aortic valve disease.
- **Renal function:** Checked before surgical intervention to ensure adequate kidney function.

e) Cardiac catheterization:

- Invasive hemodynamic testing is sometimes performed before surgical intervention to assess the severity of aortic stenosis or regurgitation and to evaluate coronary artery disease.

4. Explanation of Investigations:

- **Echocardiography:** Measures valve anatomy and function, including the pressure gradient across the aortic valve and left ventricular ejection fraction.
- **ECG:** Detects left ventricular hypertrophy, which occurs due to increased afterload in aortic stenosis or volume overload in aortic regurgitation.
- **Chest X-ray:** Helps assess the size of the heart and any signs of pulmonary congestion.
- **BNP:** A hormone released by the heart in response to ventricular stretching; elevated levels indicate heart failure.

5. Diagnosis Criteria for Aortic Valve Disease:

Aortic Stenosis:

- **Severe aortic stenosis** is defined by echocardiographic criteria:

- **Aortic valve area (AVA)** < 1.0 cm².
- **Mean pressure gradient** > 40 mmHg.
- **Jet velocity** > 4.0 m/s.

Aortic Regurgitation:

- **Severe aortic regurgitation** is defined by:
 - **Regurgitant volume** > 60 mL per beat.
 - **Regurgitant fraction** > 50%.
 - **Left ventricular end-diastolic diameter** > 70 mm.

6. First-Line Therapy According to Guidelines:

Aortic Stenosis:

1. **Aortic Valve Replacement (AVR):**
 - **Indication:** Symptomatic severe aortic stenosis or asymptomatic severe stenosis with left ventricular dysfunction.
 - **Types:** Surgical AVR or **Transcatheter Aortic Valve Implantation (TAVI)** in patients at high surgical risk.
2. **Medical management:**
 - **Beta-blockers** or **ACE inhibitors:** May be used for coexisting hypertension but must be used cautiously due to the fixed cardiac output in severe aortic stenosis.

Aortic Regurgitation:

1. **Aortic Valve Replacement (AVR):**
 - **Indication:** Symptomatic patients with severe aortic regurgitation or asymptomatic patients with evidence of left ventricular dilation or dysfunction.
2. **Medical management:**
 - **ACE inhibitors** (e.g., **ramipril**, starting dose 2.5 mg daily):
 - Mechanism: Reduces afterload and ventricular stress in aortic regurgitation.
 - **Diuretics:** May be used to manage symptoms of heart failure.

7. Contraindications and Second-Line Therapy:

- **Contraindications to AVR or TAVI:** Significant frailty, advanced comorbidities, or severe renal failure may preclude surgical intervention.
- **Second-line therapy:**
 - For patients not eligible for surgery or those who decline intervention, **ACE inhibitors** and **vasodilators** (e.g., **hydralazine**) may be used to reduce afterload in aortic regurgitation.

8. Routine Monitoring and Follow-Up:

- **Echocardiography:** Regular follow-up with echocardiography is necessary to monitor disease progression.
 - **Mild aortic valve disease:** Echo every 3-5 years.
 - **Moderate disease:** Echo every 1-2 years.
 - **Severe disease:** Echo every 6-12 months or sooner if symptoms develop.
- **Blood tests:**
 - **BNP** levels can be monitored periodically to assess heart failure progression.
 - **Renal function** should be monitored, especially in patients on ACE inhibitors or diuretics.

Summary of Key Points for Aortic Valve Disease:

- **Aortic valve disease** can present as either **aortic stenosis** (narrowed valve) or **aortic regurgitation** (leaky valve), each leading to distinct hemodynamic changes and clinical presentations.
- **Aortic stenosis** typically presents with **dyspnoea, angina, and syncope**, while **aortic regurgitation** often presents with **dyspnoea, palpitations, and a wide pulse pressure**.
- **Echocardiography** is the gold standard for diagnosis and assessment of the severity of aortic valve disease.
- **Surgical aortic valve replacement (AVR)** or **TAVI** is the definitive treatment for symptomatic severe disease, with medical management serving as a bridge or palliative option in those unfit for surgery.
- **Routine follow-up** with echocardiography and monitoring of heart failure markers is essential for managing progression and planning timely intervention.

74. Mitral Valve Disease

1. Detailed Definition of Mitral Valve Disease:

Mitral valve disease refers to conditions affecting the mitral valve, which regulates blood flow between the left atrium and left ventricle. It includes **mitral stenosis (MS)**, where the valve is narrowed and obstructs blood flow, and **mitral regurgitation (MR)**, where the valve is incompetent and allows backflow of blood into the left atrium. These conditions can lead to heart failure, atrial fibrillation, and other complications if left untreated.

2. Common Presenting Complaints and Symptoms:

Mitral Stenosis (MS):

- **Dyspnoea:** Shortness of breath, especially with exertion, is the most common symptom due to increased left atrial pressure and pulmonary congestion.
- **Orthopnoea** and **paroxysmal nocturnal dyspnoea:** Due to worsening pulmonary congestion in recumbent positions.
- **Fatigue:** Due to reduced cardiac output.
- **Palpitations:** Frequently due to atrial fibrillation.
- **Hemoptysis:** Blood-stained sputum due to elevated pulmonary pressures and rupture of bronchial veins.

Mitral Regurgitation (MR):

- **Dyspnoea:** Progressive shortness of breath on exertion and at rest.
- **Fatigue:** Due to reduced forward cardiac output.
- **Palpitations:** From atrial fibrillation due to left atrial enlargement.
- **Orthopnoea:** Shortness of breath when lying down.
- **Peripheral oedema:** Seen in advanced cases with right-sided heart failure.

Signs of Mitral Valve Disease:

- **Mitral stenosis:**
 - **Mid-diastolic murmur** heard best at the apex, often with an **opening snap**.
 - **Loud S1:** Indicates stiff mitral leaflets.
 - **Malar flush:** A reddish-purple discoloration of the cheeks due to reduced cardiac output.
- **Mitral regurgitation:**
 - **Pansystolic murmur** heard best at the apex, radiating to the axilla.
 - **Displaced apical impulse:** Reflects left ventricular enlargement.

- **Soft S1:** Indicates a lack of closure of the mitral valve.

3. First-Line Investigations:

a) Echocardiography:

- **Key diagnostic tool** for mitral valve disease.
- **Mitral stenosis:** Thickened mitral valve leaflets with restricted mobility and increased pressure gradient across the valve.
- **Mitral regurgitation:** Shows mitral valve prolapse, flail leaflet, or annular dilation with regurgitant flow into the left atrium.

b) Electrocardiogram (ECG):

- **Mitral stenosis:** May show signs of **left atrial enlargement** (bifid P waves) and **atrial fibrillation**.
- **Mitral regurgitation:** Can also show atrial fibrillation or signs of **left ventricular hypertrophy** (LVH) due to volume overload.

c) Chest X-ray:

- **Mitral stenosis:** Enlarged left atrium (double contour sign), pulmonary congestion, and possible pulmonary oedema.
- **Mitral regurgitation:** Left atrial and ventricular enlargement, and signs of heart failure (e.g., pulmonary oedema).

d) Blood Tests:

- **Brain natriuretic peptide (BNP):** Elevated in patients with heart failure due to volume overload.
- **Complete blood count (CBC):** To rule out anaemia, which can worsen symptoms.
- **Renal function:** Important before any intervention to assess kidney function.

e) Cardiac catheterization:

- Used to assess **pulmonary artery pressures** and confirm the severity of stenosis or regurgitation when non-invasive tests are inconclusive or before surgery.

4. Explanation of Investigations:

- **Echocardiography:** Measures mitral valve anatomy and function, including valve area and pressure gradients in stenosis or regurgitant volume in mitral regurgitation.
- **ECG:** Detects atrial enlargement and atrial fibrillation, which are common in mitral valve disease.
- **Chest X-ray:** Helps evaluate the size of the heart and the presence of pulmonary congestion.
- **BNP:** Elevated in cases of heart failure due to increased left atrial pressure and fluid overload.

5. Diagnosis Criteria for Mitral Valve Disease:

Mitral Stenosis:

- **Valve area:**
 - **Severe MS** is defined by a mitral valve area $< 1.5 \text{ cm}^2$.
- **Mean pressure gradient:**
 - Severe stenosis is characterized by a pressure gradient $> 10 \text{ mmHg}$.

Mitral Regurgitation:

- **Regurgitant volume:** Severe MR is defined by a regurgitant volume $> 60 \text{ mL}$ per beat.
- **Regurgitant fraction:** Severe MR if $> 50\%$.
- **Effective regurgitant orifice area:** Severe MR if $> 0.4 \text{ cm}^2$.

6. First-Line Therapy According to Guidelines:

Mitral Stenosis:

1. **Percutaneous Mitral Balloon Valvuloplasty (PMBV):**
 - First-line treatment for **symptomatic severe mitral stenosis** without significant mitral regurgitation.
 - Indicated for **younger patients** or those with non-calcified valves.
2. **Surgical Mitral Valve Replacement:**
 - Indicated for patients with severe symptoms who are not candidates for balloon valvuloplasty or those with significant mitral regurgitation.
3. **Medical management:**
 - **Diuretics** (e.g., **furosemide** 20–80 mg daily) to reduce pulmonary congestion.
 - **Beta-blockers** or **calcium channel blockers**: Used to control heart rate in atrial fibrillation and reduce symptoms by prolonging diastole.

Mitral Regurgitation:

1. **Mitral Valve Repair or Replacement:**
 - **Mitral valve repair** is preferred when feasible, particularly in **severe symptomatic MR**.
 - **Mitral valve replacement** may be required in cases where repair is not possible or in severe regurgitation with left ventricular dysfunction.
2. **Medical management:**
 - **ACE inhibitors** (e.g., **ramipril** 2.5–10 mg daily) or **ARBs**: Reduce afterload and improve forward flow in patients with left ventricular dysfunction.
 - **Diuretics**: Used to manage heart failure symptoms.

7. Contraindications and Second-Line Therapy:

- **Contraindications to valve surgery:** Advanced comorbidities, frailty, or severe pulmonary hypertension may preclude surgical intervention.
- **Second-line therapy:**
 - For patients not suitable for surgery, **medical management** with ACE inhibitors, diuretics, and heart rate control is essential to manage symptoms and reduce disease progression.

8. Routine Monitoring and Follow-Up:

- **Echocardiography:** Regular follow-up to monitor disease progression and the need for intervention.
 - **Mild mitral disease:** Echo every 3–5 years.
 - **Moderate disease:** Echo every 1–2 years.
 - **Severe disease:** Echo every 6–12 months, especially if symptomatic.
- **Blood tests:**
 - Monitor **renal function** regularly in patients on diuretics and ACE inhibitors.
 - **BNP** levels can be used to assess heart failure progression.

Summary of Key Points for Mitral Valve Disease:

- **Mitral valve disease** includes both **mitral stenosis** (narrowing of the mitral valve) and **mitral regurgitation** (incompetence of the mitral valve, allowing backflow of blood).
- **Mitral stenosis** presents with **dyspnoea, fatigue, and atrial fibrillation**, while **mitral regurgitation** presents with **dyspnoea, palpitations, and heart failure**.

- **Echocardiography** is the gold standard for diagnosing and assessing the severity of both mitral stenosis and mitral regurgitation.
- **Percutaneous mitral balloon valvuloplasty** is first-line therapy for mitral stenosis, while **mitral valve repair or replacement** is the definitive treatment for severe mitral regurgitation.
- **Routine follow-up** with echocardiography and symptom monitoring is essential to guide the timing of intervention.

75. Right Heart Valve Disease

1. Detailed Definition of Right Heart Valve Disease:

Right heart valve disease refers to disorders affecting the **tricuspid** and **pulmonary valves**, which control blood flow between the right atrium and right ventricle and from the right ventricle into the pulmonary artery, respectively. The two main conditions are **tricuspid stenosis (TS)**, **tricuspid regurgitation (TR)**, **pulmonary stenosis (PS)**, and **pulmonary regurgitation (PR)**. These conditions can impair the function of the right side of the heart, leading to symptoms of right-sided heart failure and reduced blood flow to the lungs.

2. Common Presenting Complaints and Symptoms:

Tricuspid Stenosis (TS):

- **Fatigue:** Due to reduced cardiac output.
- **Abdominal discomfort:** Secondary to hepatic congestion.
- **Ascites** and **peripheral oedema:** Due to systemic venous congestion.
- **Jugular venous distension:** Prominent, with a slow y-descent.

Tricuspid Regurgitation (TR):

- **Peripheral oedema:** Swelling of the legs and feet due to fluid retention.
- **Ascites:** Accumulation of fluid in the abdomen.
- **Fatigue:** Due to reduced cardiac output.
- **Palpitations:** From right atrial enlargement and possible atrial fibrillation.
- **Jugular venous distension (JVD):** May show prominent v-waves.

Pulmonary Stenosis (PS):

- **Dyspnoea:** Shortness of breath, especially on exertion.
- **Fatigue:** Due to limited cardiac output.
- **Cyanosis:** In severe cases due to reduced pulmonary blood flow.
- **Palpitations:** Can occur with right ventricular hypertrophy and strain.

Pulmonary Regurgitation (PR):

- **Dyspnoea:** Progressive shortness of breath, especially with exertion.
- **Fatigue:** Due to reduced cardiac output.
- **Peripheral oedema:** Late finding due to right heart failure.
- **Palpitations:** Occurs in cases of right ventricular enlargement.

Signs of Right Heart Valve Disease:

- **Tricuspid stenosis:**
 - **Diastolic murmur** at the left lower sternal border, increasing with inspiration.
 - **Hepatomegaly:** Due to venous congestion.
 - **Ascites** and **peripheral oedema**.
- **Tricuspid regurgitation:**
 - **Holosystolic murmur** at the left lower sternal border, increasing with inspiration (**Carvallo's sign**).
 - **Pulsatile liver** and **hepatomegaly**.

- **Pulmonary stenosis:**
 - **Ejection systolic murmur** heard loudest at the left upper sternal border.
 - **Right ventricular heave:** Due to right ventricular hypertrophy.
- **Pulmonary regurgitation:**
 - **Early diastolic murmur** at the left upper sternal border (Graham Steell murmur).
 - **Signs of right-sided heart failure** in advanced cases.

3. First-Line Investigations:

a) Echocardiography:

- **Gold standard** for diagnosing right heart valve disease.
- **Tricuspid stenosis:** Thickened and immobile tricuspid valve leaflets, with reduced valve area.
- **Tricuspid regurgitation:** Dilated right atrium and ventricle with regurgitant flow into the right atrium.
- **Pulmonary stenosis:** Right ventricular hypertrophy and increased pressure gradient across the pulmonary valve.
- **Pulmonary regurgitation:** Dilated right ventricle and regurgitant flow from the pulmonary artery into the right ventricle.

b) Electrocardiogram (ECG):

- **Tricuspid stenosis:** Right atrial enlargement (tall P waves in lead II).
- **Tricuspid regurgitation:** May show signs of **right atrial enlargement** and **right ventricular hypertrophy**.
- **Pulmonary stenosis:** Right ventricular hypertrophy (tall R waves in V1 and V2).
- **Pulmonary regurgitation:** May show signs of **right ventricular hypertrophy** in chronic cases.

c) Chest X-ray:

- **Tricuspid stenosis:** Enlarged right atrium.
- **Tricuspid regurgitation:** Enlarged right atrium and ventricle, prominent pulmonary arteries in advanced cases.
- **Pulmonary stenosis:** Post-stenotic dilation of the pulmonary artery and right ventricular hypertrophy.
- **Pulmonary regurgitation:** Enlarged right ventricle.

d) Blood Tests:

- **Brain natriuretic peptide (BNP):** Elevated in heart failure, indicating right ventricular strain.
- **Liver function tests (LFTs):** Elevated in patients with hepatic congestion due to right-sided heart failure.

e) Cardiac catheterization:

- Used to measure **pressure gradients** across the tricuspid or pulmonary valves and assess pulmonary artery pressures in severe cases.

4. Explanation of Investigations:

- **Echocardiography:** Assesses the anatomy and function of the right-sided valves, including valve area, pressure gradients, and right ventricular function.
- **ECG:** Detects right atrial enlargement or right ventricular hypertrophy due to pressure or volume overload.
- **Chest X-ray:** Assesses for cardiomegaly and pulmonary artery dilation.

- **BNP:** Reflects the degree of heart failure and right ventricular strain.

5. Diagnosis Criteria for Right Heart Valve Disease:

Tricuspid Stenosis:

- **Valve area:** Severe stenosis if the valve area is $< 1.0 \text{ cm}^2$.
- **Mean pressure gradient:** Severe stenosis if $> 5 \text{ mmHg}$.

Tricuspid Regurgitation:

- **Regurgitant volume:** Severe if $> 45 \text{ mL}$ per beat.
- **Effective regurgitant orifice area:** Severe if $> 0.4 \text{ cm}^2$.

Pulmonary Stenosis:

- **Pressure gradient:** Severe stenosis if $> 60 \text{ mmHg}$.

Pulmonary Regurgitation:

- **Regurgitant fraction:** Severe regurgitation if $> 40\%$.

6. First-Line Therapy According to Guidelines:

Tricuspid Stenosis:

1. **Surgical or Percutaneous Balloon Valvuloplasty:**
 - **Indication:** Symptomatic patients with severe tricuspid stenosis.
 - **Mechanism:** Relieves obstruction by widening the stenotic valve.
2. **Medical management:**
 - **Diuretics** (e.g., **furosemide** 20-80 mg daily) to manage symptoms of fluid overload.

Tricuspid Regurgitation:

1. **Surgical Valve Repair or Replacement:**
 - **Indication:** Severe symptomatic tricuspid regurgitation or in patients undergoing left-sided valve surgery.
2. **Medical management:**
 - **Diuretics:** To manage systemic congestion.
 - **ACE inhibitors** or **beta-blockers:** To manage heart failure if present.

Pulmonary Stenosis:

1. **Percutaneous Balloon Valvuloplasty:**
 - **Indication:** Severe symptomatic pulmonary stenosis, especially in young patients.
 - **Mechanism:** Expands the narrowed pulmonary valve.
2. **Surgical valve replacement:** Reserved for cases where valvuloplasty is not feasible.

Pulmonary Regurgitation:

1. **Surgical Valve Replacement:**
 - **Indication:** Severe symptomatic pulmonary regurgitation with right ventricular enlargement or dysfunction.
2. **Medical management:**
 - **Diuretics** and **afterload reducers** for heart failure management.

7. Contraindications and Second-Line Therapy:

- **Contraindications to surgical interventions:** Significant comorbidities, frailty, or advanced heart failure may preclude surgery.
- **Second-line therapy:** For patients not suitable for surgery, **medical management** with diuretics and ACE inhibitors may alleviate symptoms.

8. Routine Monitoring and Follow-Up:

- **Echocardiography:** Regular follow-up to monitor valve function and right ventricular size and function.
 - **Mild disease:** Echo every 3–5 years.
 - **Moderate disease:** Echo every 1–2 years.
 - **Severe disease:** Echo every 6–12 months.
- **Blood tests:**
 - Monitor **BNP** levels and **liver function tests** in patients with heart failure or hepatic congestion.
 - **Renal function** should be regularly monitored in patients on diuretics.

Summary of Key Points for Right Heart Valve Disease:

- **Right heart valve disease** primarily affects the **tricuspid** and **pulmonary valves** and can present as **stenosis** or **regurgitation** of these valves.
- **Tricuspid stenosis** presents with **fatigue, ascites, and peripheral oedema**, while **tricuspid regurgitation** presents with **jugular venous distension, pulsatile liver, and holosystolic murmur**.
- **Pulmonary stenosis** typically presents with **dyspnoea, fatigue, and a systolic murmur**, while **pulmonary regurgitation** presents with **dyspnoea, fatigue, and right-sided heart failure**.
- **Echocardiography** is the gold standard for diagnosing and assessing right heart valve disease, with **surgical or percutaneous interventions** often required for severe cases.
- **Routine follow-up** with echocardiography and symptom monitoring is essential to guide the timing of intervention.

76. Myocarditis

1. Detailed Definition of Myocarditis:

Myocarditis is the inflammation of the heart muscle (**myocardium**) often caused by infections, autoimmune diseases, toxins, or drug reactions. The condition can lead to impaired cardiac function, arrhythmias, and in severe cases, heart failure. It may present as an acute or chronic condition and ranges in severity from asymptomatic to life-threatening.

2. Common Presenting Complaints and Symptoms:

Acute Myocarditis:

- **Chest pain:** May resemble angina and can be pleuritic.
- **Fatigue** and **general malaise**.
- **dyspnoea:** Shortness of breath due to impaired cardiac function.
- **Palpitations:** Arrhythmias such as premature ventricular contractions or atrial fibrillation.
- **Fever:** Particularly if associated with an infectious cause.
- **Syncope:** Due to arrhythmias.
- **Heart failure symptoms:** Including orthopnoea, paroxysmal nocturnal dyspnoea, and peripheral oedema in severe cases.

Chronic Myocarditis:

- Symptoms may be less specific and include **progressive fatigue, exercise intolerance, and dyspnoea**. Chronic myocarditis can lead to dilated cardiomyopathy and progressive heart failure.

3. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Non-specific ST segment and T-wave changes.**
- **Sinus tachycardia.**
- **Arrhythmias**, including atrial fibrillation or ventricular tachycardia.
- **Heart block:** May occur in severe cases.

b) Blood Tests:

1. **Cardiac biomarkers:**
 - **Troponin I and T:** Elevated in cases where there is myocardial damage, helping differentiate myocarditis from non-cardiac causes of chest pain.
 - **Creatine kinase-MB (CK-MB):** Also elevated in myocardial injury.
2. **Inflammatory markers:**
 - **C-reactive protein (CRP)** and **erythrocyte sedimentation rate (ESR):** Elevated in active inflammation.
3. **Viral serology:**
 - Especially for common viral causes like **Coxsackievirus**, **adenovirus**, and **parvovirus B19**.
4. **Autoimmune screening:**
 - Antinuclear antibodies (ANA), rheumatoid factor (RF), or other tests depending on suspected autoimmune causes.

c) Echocardiography:

- Used to assess the **function of the myocardium** and detect **wall motion abnormalities**.
- **Left ventricular dysfunction** may be present, especially in severe or chronic myocarditis.

d) Cardiac Magnetic Resonance Imaging (MRI):

- **MRI with gadolinium enhancement** can detect myocardial inflammation, oedema, and fibrosis.
- **Late gadolinium enhancement (LGE)** indicates areas of myocardial scarring or necrosis.

e) Endomyocardial Biopsy:

- **Gold standard** for definitive diagnosis, but used only in select cases.
- Biopsy shows **inflammatory infiltrates** in the myocardium, and may demonstrate **myocyte necrosis**.

4. Explanation of Investigations:

- **ECG:** Helps identify arrhythmias and myocardial injury, but findings are often non-specific.
- **Cardiac biomarkers:** Elevated troponin and CK-MB indicate myocardial damage.
- **Echocardiography:** Assesses the function of the heart and the presence of heart failure or wall motion abnormalities.
- **Cardiac MRI:** Provides a detailed view of inflammation, oedema, and fibrosis in the heart muscle.
- **Endomyocardial biopsy:** Reserved for severe or unexplained cases and confirms the diagnosis by identifying inflammation and myocyte damage.

5. Diagnosis Criteria for Myocarditis:

The diagnosis of myocarditis is typically based on **clinical suspicion, imaging,** and **biomarkers**, with definitive diagnosis requiring biopsy in certain cases.

- **Clinical features:** Chest pain, heart failure, or arrhythmias.
- **ECG changes:** Non-specific ST-T wave changes, arrhythmias, or conduction disturbances.
- **Cardiac biomarkers:** Elevated troponin or CK-MB.
- **Imaging:**
 - **Cardiac MRI:** Findings of myocardial inflammation or fibrosis.
 - **Echocardiography:** Reduced left ventricular function or wall motion abnormalities.

Reference guidelines for diagnosis include the **European Society of Cardiology (ESC)** and **American Heart Association (AHA)**, which recommend using a combination of clinical, imaging, and biomarker criteria.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

1. **Rest and avoidance of strenuous physical activity:** To reduce stress on the heart while it heals.

b) Medications:

1. **Heart failure management:**
 - **ACE inhibitors** (e.g., **ramipril** 2.5-10 mg daily) or **angiotensin receptor blockers (ARBs)**: Reduce afterload and improve cardiac function.
 - **Beta-blockers** (e.g., **bisoprolol** 1.25-10 mg daily): Used in patients with heart failure or reduced ejection fraction.
 - **Diuretics** (e.g., **furosemide** 20-80 mg daily): For fluid overload in heart failure.
2. **Arrhythmia management:**
 - Anti-arrhythmic drugs or **implantable cardioverter-defibrillators (ICDs)** may be necessary in patients with ventricular arrhythmias.
3. **Immunosuppressive therapy:**
 - In cases of autoimmune myocarditis, **corticosteroids** (e.g., **prednisolone** 1 mg/kg/day) or other immunosuppressive agents like **azathioprine** may be considered under specialist guidance.
4. **Antiviral therapy:**
 - For certain viral myocarditis (e.g., in cases of HIV or hepatitis), antiviral treatment may be appropriate.

7. Contraindications and Second-Line Therapy:

- **Contraindications** to immunosuppressive therapy: Active infections should be ruled out before initiating immunosuppressants to avoid exacerbating the infection.

Second-Line Therapy:

- For patients with severe heart failure despite optimal medical therapy, **mechanical circulatory support** (e.g., **left ventricular assist device (LVAD)**) or **heart transplantation** may be considered in advanced cases.

8. Routine Monitoring and Follow-Up:

- **Echocardiography:** Regular follow-up is essential to monitor changes in left ventricular function and progression of heart failure.
- **Blood tests:**

- Monitor **cardiac biomarkers** (troponin) and **inflammatory markers** (CRP, ESR) to assess for ongoing inflammation.
 - Regular monitoring of **renal function** in patients on diuretics or ACE inhibitors.
- **Cardiac MRI:** May be repeated to assess for resolution of myocardial inflammation or progression of fibrosis.

Summary of Key Points for Myocarditis:

- **Myocarditis** is inflammation of the heart muscle and can result from infections, autoimmune diseases, or toxins. It can range from asymptomatic cases to severe heart failure and arrhythmias.
- Symptoms include **chest pain, dyspnoea, palpitations, and fatigue**, with clinical signs of **heart failure** or **arrhythmias** in severe cases.
- **Echocardiography** and **cardiac MRI** are key imaging modalities, with **elevated cardiac biomarkers** (troponin) indicating myocardial injury.
- Treatment is primarily **supportive**, including **ACE inhibitors, beta-blockers, and diuretics** for heart failure, while **immunosuppressive therapy** may be needed for autoimmune causes.
- **Regular monitoring** with echocardiography and biomarkers is essential for assessing progression and treatment response, and in severe cases, **heart transplantation** may be required.

77. Cardiomyopathy

1. Detailed Definition of Cardiomyopathy:

Cardiomyopathy refers to a group of diseases of the heart muscle that affect its structure and function, often leading to heart failure, arrhythmias, and other complications. The three main types of cardiomyopathy are:

1. **Dilated Cardiomyopathy (DCM):** The heart muscle becomes weakened and enlarged, leading to reduced pumping efficiency.
2. **Hypertrophic Cardiomyopathy (HCM):** The heart muscle becomes abnormally thickened, which can obstruct blood flow and impair relaxation.
3. **Restrictive Cardiomyopathy (RCM):** The heart muscle becomes stiff, leading to impaired filling of the ventricles during diastole.

2. Common Presenting Complaints and Symptoms:

Dilated Cardiomyopathy (DCM):

- **dyspnoea:** Shortness of breath, especially on exertion or when lying down.
- **Fatigue:** Due to reduced cardiac output.
- **Peripheral oedema:** Swelling in the legs, ankles, and abdomen.
- **Palpitations:** Due to arrhythmias like atrial fibrillation or ventricular tachycardia.
- **Orthopnoea** and **paroxysmal nocturnal dyspnoea (PND):** From worsening heart failure.

Hypertrophic Cardiomyopathy (HCM):

- **dyspnoea:** Due to diastolic dysfunction (impaired filling).
- **Chest pain (angina):** Especially with exertion due to reduced blood flow.
- **Syncope:** Fainting, often with exercise or exertion, due to outflow obstruction or arrhythmias.
- **Palpitations:** Arrhythmias, including atrial fibrillation or ventricular arrhythmias.

- **Sudden cardiac death:** Particularly in young athletes, often due to ventricular arrhythmias.

Restrictive Cardiomyopathy (RCM):

- **Dyspnoea:** Progressive shortness of breath.
- **Fatigue:** Due to poor cardiac output.
- **Peripheral oedema, ascites, and jugular venous distension:** Due to right heart failure.
- **Orthopnoea and PND:** Due to left-sided heart failure.

3. First-Line Investigations:

a) Electrocardiogram (ECG):

- **Dilated Cardiomyopathy:** May show **non-specific ST-T wave changes, left bundle branch block, or arrhythmias** (e.g., atrial fibrillation).
- **Hypertrophic Cardiomyopathy:** Left ventricular hypertrophy (LVH) with **deep Q waves** in the lateral and inferior leads.
- **Restrictive Cardiomyopathy:** Low-voltage QRS complexes in amyloidosis, and signs of atrial enlargement or arrhythmias.

b) Echocardiography:

- **Dilated Cardiomyopathy:** Shows **dilated ventricles** with **reduced ejection fraction**.
- **Hypertrophic Cardiomyopathy:** Shows **asymmetrical septal hypertrophy**, with possible left ventricular outflow tract obstruction.
- **Restrictive Cardiomyopathy:** Shows **normal ventricular size** but **impaired diastolic filling** with **enlarged atria**.

c) Cardiac Magnetic Resonance Imaging (MRI):

- Useful for assessing myocardial structure, **fibrosis**, or **scarring**, particularly in hypertrophic and restrictive cardiomyopathies.
- **Late gadolinium enhancement (LGE)** on MRI can show areas of fibrosis or scarring in HCM and RCM.

d) Blood Tests:

- **Brain natriuretic peptide (BNP) or NT-proBNP:** Elevated in heart failure, indicating ventricular stretch.
- **Troponin:** Elevated in myocarditis or acute myocardial injury.
- **Serum ferritin and transferrin saturation:** To check for hemochromatosis in suspected DCM.

e) Genetic Testing:

- Especially important in **hypertrophic cardiomyopathy** as it is often familial. Genetic testing is recommended for family members of patients diagnosed with HCM.

4. Explanation of Investigations:

- **Echocardiography:** Evaluates the structure and function of the heart, including ventricular size, wall thickness, and systolic/diastolic function.
- **Cardiac MRI:** Provides detailed imaging of myocardial structure, including areas of fibrosis or scar tissue.
- **BNP:** Reflects the degree of heart failure and is useful for monitoring disease progression.
- **Genetic testing:** Identifies familial mutations, particularly in HCM, which can guide family screening and management.

5. Diagnosis Criteria for Cardiomyopathy:

Dilated Cardiomyopathy (DCM):

- **Left ventricular dilation** with **reduced ejection fraction** (<40%).
- **Exclusion** of other causes of ventricular dysfunction such as ischemic heart disease or valvular heart disease.

Hypertrophic Cardiomyopathy (HCM):

- **Left ventricular hypertrophy (LVH)** with a wall thickness ≥ 15 mm on echocardiogram.
- **Asymmetrical septal hypertrophy** is common, but hypertrophy may also be concentric.
- **Genetic mutations:** Confirmed in about 60-70% of cases.

Restrictive Cardiomyopathy (RCM):

- **Normal or near-normal ventricular size**, with **marked bi-atrial enlargement** and **impaired diastolic filling**.
- **Endomyocardial biopsy:** May be required to diagnose specific causes such as amyloidosis.

6. First-Line Therapy According to Guidelines:**Dilated Cardiomyopathy (DCM):**

1. **Heart failure management:**
 - **ACE inhibitors** (e.g., **ramipril** 2.5-10 mg daily): To reduce afterload and improve symptoms.
 - **Beta-blockers** (e.g., **bisoprolol** 1.25-10 mg daily): To reduce mortality and improve left ventricular function.
 - **Diuretics** (e.g., **furosemide** 20-80 mg daily): To manage fluid overload.
 - **Mineralocorticoid receptor antagonists (MRAs):** **Spironolactone** or **eplerenone** may be used to further reduce mortality.
2. **Implantable Cardioverter Defibrillator (ICD):**
 - Considered in patients with severe DCM and ejection fraction <35% to prevent sudden cardiac death.

Hypertrophic Cardiomyopathy (HCM):

1. **Beta-blockers:**
 - **Metoprolol** or **bisoprolol** to reduce heart rate and improve symptoms of outflow obstruction.
2. **Calcium channel blockers** (e.g., **verapamil**):
 - Used in patients who cannot tolerate beta-blockers.
3. **Surgical myectomy or alcohol septal ablation:**
 - Indicated in patients with severe symptoms due to **left ventricular outflow tract (LVOT) obstruction**.
4. **ICD:**
 - Recommended in high-risk patients to prevent sudden cardiac death.

Restrictive Cardiomyopathy (RCM):

1. **Diuretics:**
 - Used to relieve symptoms of fluid overload.
2. **Heart failure management:**
 - Similar to DCM, with ACE inhibitors, beta-blockers, and MRAs used based on symptoms.
3. **Specific therapies:**
 - For example, in **amyloidosis**, **chemotherapy** or **bone marrow transplantation** may be indicated.

7. Contraindications and Second-Line Therapy:

- **Hypertrophic Cardiomyopathy:**
 - Avoid **vasodilators** (such as nitrates) and **diuretics** in patients with outflow tract obstruction, as they can worsen symptoms by reducing preload.

Second-Line Therapy:

- For **DCM**, **cardiac resynchronization therapy (CRT)** can improve outcomes in patients with conduction delays and heart failure.
- **Heart transplantation** may be considered in advanced cases of **DCM** or **RCM** refractory to medical therapy.

8. Routine Monitoring and Follow-Up:

- **Echocardiography:** Regular follow-up to assess ventricular size, function, and wall thickness.
 - **Mild cardiomyopathy:** Echo every 1-2 years.
 - **Moderate to severe disease:** Echo every 6-12 months or more frequently if symptoms worsen.
- **ECG and Holter monitoring:** Periodically check for arrhythmias, especially in HCM where ventricular arrhythmias can be life-threatening.
- **Genetic counselling and screening** for family members of patients with hypertrophic cardiomyopathy or familial dilated cardiomyopathy.

Summary of Key Points for Cardiomyopathy:

- **Cardiomyopathy** includes **dilated**, **hypertrophic**, and **restrictive** forms, each leading to distinct pathophysiological changes and clinical presentations.
- **Dilated cardiomyopathy (DCM)** presents with symptoms of heart failure, while **hypertrophic cardiomyopathy (HCM)** presents with dyspnoea, chest pain, and a risk of sudden cardiac death.
- **Restrictive cardiomyopathy (RCM)** is characterized by stiff ventricles and presents with symptoms of right-sided heart failure.
- **Echocardiography** is the key diagnostic tool for assessing the structure and function of the heart.
- Treatment focuses on managing **heart failure** and preventing **arrhythmias**, with **surgical interventions** or **ICD** placement considered for high-risk patients.
- **Routine follow-up** with echocardiography, ECG, and genetic screening is essential for monitoring disease progression and managing complications.

Dermatology

78. Atopic Dermatitis (Atopic Eczema)

1. Description of Atopic Dermatitis (Eczema):

Atopic dermatitis, commonly referred to as **atopic eczema**, is a chronic inflammatory skin condition predominantly seen in children but also affecting adults. It is associated with the **atopic triad**—asthma, allergic rhinitis, and eczema—making it a key feature in patients with a family or personal history of **atopy**. The exact cause of atopic dermatitis is not fully understood, but it is strongly linked to **genetic** and **environmental factors**, leading to a **defective skin barrier**.

2. Epidemiology:

- **Prevalence:** Affects approximately **20% of children under the age of 12** in the UK, with most cases presenting before the age of 5.
- **Chronic nature:** While many children outgrow atopic dermatitis, some experience persistence into adulthood, often with intermittent flares.

3. Causes and Exacerbating Factors:

Primary Cause:

- **Genetic defect in skin barrier function:** Mutations in the **filaggrin (FLG) gene**, which encodes a key structural protein in the skin, have been identified as a common cause. Filaggrin deficiency leads to impaired skin barrier function, increasing **water loss** and making the skin more permeable to allergens and irritants.

Exacerbating Factors:

1. **Infections:** Bacterial (e.g., **Staphylococcus aureus**), viral (e.g., **herpes simplex**), and fungal infections.
2. **Allergens:** Dust mites, pet dander, pollens, and foods.
3. **Environmental triggers:** Heat, sweating, dry environments, and irritants like harsh soaps and detergents.
4. **Occupational factors:** Repeated exposure to chemicals and irritants.
5. **Psychological stress:** Can worsen symptoms in some individuals.

4. Presentation:

Acute Atopic Dermatitis:

- **Itchy papules and vesicles:** Often **weepy (exudative)**, particularly in younger children.
- **Distribution:** Typically affects the face and **extensor surfaces** (e.g., arms, legs) in infants.
- **Severe pruritus:** Itching is the hallmark symptom, often leading to **scratching**, which worsens the condition.

Chronic Atopic Dermatitis:

- **Dry, scaly, itchy patches:** Commonly seen in older children and adults, particularly on **flexural surfaces** (e.g., behind the knees, inside the elbows).
- **Lichenification:** Thickening of the skin due to chronic rubbing or scratching.
- **Pigmentary changes:** Both **hypopigmentation** and **hyperpigmentation** can occur due to chronic inflammation, particularly in richly pigmented skin.

In Richly Pigmented Skin:

- **Papular eczema or follicular eczema:** Eczema may present as **brown, grey, or purple bumps**.
- **Erythema:** May appear as **grey or brown** instead of red in richly pigmented skin.

Nail Involvement:

- **Nail changes:** **Pitting** and **ridging** of the nails are occasionally seen, reflecting chronic inflammation.

5. Management:

General Measures:

- **Avoidance of triggers:** Identifying and avoiding known exacerbating factors (e.g., allergens, irritants) is crucial.
- **Frequent emollient use:** Emollients should be applied **liberally and frequently** to prevent dryness and repair the skin barrier. **Soap substitutes** and **bath oils** are recommended to avoid further irritation.
- **Wet wraps or bandages:** Can be applied to areas of severe eczema to enhance emollient absorption and reduce scratching.

Topical Therapies:

- **Topical corticosteroids:**
 - **Low-potency steroids** (e.g., **hydrocortisone 1%**) for sensitive areas like the face and flexures.
 - **Moderate to high-potency steroids** (e.g., **betamethasone**) for more severe areas on the body.
 - Steroids should be used sparingly to avoid skin thinning.
- **Topical calcineurin inhibitors:**
 - **Tacrolimus** or **pimecrolimus** can be used as **steroid-sparing agents**, particularly for long-term maintenance therapy on sensitive areas such as the face.

Oral Therapies:

- **Antihistamines:** Can provide **symptomatic relief** of itching, especially during flare-ups or at night. **Sedating antihistamines** (e.g., **hydroxyzine**) may help with sleep disturbances.
- **Antibiotics:**
 - **Flucloxacillin** or **erythromycin** for **secondary bacterial infections** (e.g., *Staphylococcus aureus*).
- **Antivirals:**
 - **Aciclovir** for secondary infections with **herpes simplex virus**, which can cause **eczema herpeticum**, a severe complication of atopic dermatitis.

Phototherapy and Immunosuppressants:

- **Phototherapy (narrowband UVB):** Effective for moderate-to-severe atopic dermatitis that does not respond to topical treatments.
- **Immunosuppressants:**
 - **Ciclosporin**, **azathioprine**, or **methotrexate** may be considered in severe, refractory cases.

Biologic Therapy:

- **Dupilumab:** A biologic agent targeting IL-4 and IL-13, approved for moderate-to-severe atopic dermatitis in patients unresponsive to conventional treatments.

6. Complications:

1. Secondary Bacterial Infections:

- Typically caused by **Staphylococcus aureus**, leading to **crusting** and **weeping** of lesions.
- **Impetiginization**: Superficial skin infection requiring systemic antibiotics.

2. Secondary Viral Infections:

- **Molluscum contagiosum**: Pearly papules with central umbilication.
- **Viral warts**: More common in patients with atopic dermatitis due to impaired skin immunity.
- **Eczema herpeticum**: Severe herpes simplex infection presenting as grouped vesicles with systemic symptoms (fever, malaise). This is a **dermatologic emergency** requiring antiviral treatment (e.g., **aciclovir**).

7. Conclusion:

Atopic dermatitis is a common, chronic skin condition affecting both children and adults. Management involves regular **use of emollients, topical anti-inflammatory therapies**, and **addressing exacerbating factors**. While many patients outgrow the condition, others may experience persistent symptoms into adulthood. Recognizing complications, such as secondary infections, and escalating treatment when necessary, including the use of **phototherapy** or **biologic agents**, is essential for optimal patient care.

79. Irritant Contact Dermatitis

1. Detailed Definition of Irritant Contact Dermatitis (ICD):

Irritant contact dermatitis (ICD) is a form of dermatitis caused by direct chemical or physical damage to the skin following exposure to an irritant. It is the most common form of contact dermatitis and results from the **non-immunologic** response of the skin to irritants such as soaps, detergents, acids, or friction. Unlike allergic contact dermatitis, ICD does not involve an allergic reaction and can occur in anyone, given sufficient exposure to the irritant.

2. Common Presenting Complaints and Symptoms:

- **Erythema (Redness)**: Red, inflamed areas of skin at the site of contact with the irritant.
- **Dryness and Scaling**: The skin may become rough and flaky, particularly with chronic exposure.
- **Pruritus (Itching)**: Mild to moderate itching may occur, although it is typically less intense than in allergic dermatitis.
- **Burning or Stinging**: A common symptom, especially during acute exposure to a strong irritant.
- **Blisters or Vesicles**: In severe cases, exposure to strong irritants may cause the formation of vesicles or blisters.
- **Cracking and Fissuring**: Prolonged irritation can cause the skin to crack and form painful fissures, particularly on the hands.

Common Sites Affected:

- **Hands**: Commonly affected due to frequent exposure to water, soaps, and cleaning agents.
- **Face**: May be involved due to exposure to cosmetic products or airborne irritants.
- **Legs**: Contact with irritant substances like hair removal creams or occupational irritants.

3. First-Line Investigations:

Irritant contact dermatitis is primarily a **clinical diagnosis** based on the patient's history of exposure to a known irritant and the appearance of the skin. Unlike allergic contact dermatitis, skin patch testing is not helpful in diagnosing ICD because it is not mediated by the immune system.

a) History and Clinical Examination:

- **Detailed history:** Asking about exposure to potential irritants, such as soaps, chemicals, or occupational substances, is key to the diagnosis.
- **Examination of the skin:** Identifying the pattern and location of dermatitis can help determine the type of irritant and confirm the diagnosis.

b) Exclusion of Allergic Contact Dermatitis:

- **Patch testing:** Although ICD does not involve allergic mechanisms, patch testing may be performed to rule out **allergic contact dermatitis** if the diagnosis is unclear or if the dermatitis is chronic or recurrent.

4. Explanation of Investigations:

- **Patch testing:** Performed when an allergic component is suspected or to exclude allergic contact dermatitis. The absence of a positive reaction to common allergens helps confirm the diagnosis of ICD.

5. Diagnosis Criteria for Irritant Contact Dermatitis:

Irritant contact dermatitis is diagnosed based on the following criteria:

- **History of exposure** to a known irritant (e.g., chemicals, soaps, detergents).
- **Onset of symptoms** soon after exposure.
- **Localized lesions** at the site of contact with the irritant.
- **Absence of systemic symptoms** (e.g., fever) unless there is an associated secondary infection.
- **Negative patch testing** for allergens, ruling out allergic contact dermatitis.

6. First-Line Therapy According to Guidelines:

The mainstay of treatment for **irritant contact dermatitis** involves **avoiding the irritant**, **protecting the skin**, and reducing inflammation with topical therapies.

a) General Measures:

1. **Avoidance of irritants:**
 - **Identification and avoidance** of the triggering substance (e.g., changing soaps, wearing gloves when handling chemicals).
 - **Barrier creams** can be used to protect the skin from repeated exposure.
2. **Emollients and Moisturizers:**
 - **Frequent application** of emollients to restore the skin barrier and prevent further irritation.
 - Greasy ointments (e.g., **petrolatum**) are preferred as they provide a longer-lasting barrier effect.

b) Topical Therapies:

1. **Topical corticosteroids:**
 - **Mild to moderate corticosteroids** (e.g., **hydrocortisone 1%** or **betamethasone valerate 0.1%**) can be used to reduce inflammation and alleviate symptoms during acute flares.
 - Steroids should be used for **short courses** to prevent skin thinning.
2. **Topical calcineurin inhibitors** (e.g., **tacrolimus** or **pimecrolimus**):

- These can be used as **steroid-sparing agents**, particularly in areas where prolonged use of steroids is undesirable (e.g., face or flexures).

c) Oral Therapies:

1. Antihistamines:

- **Oral antihistamines** may help reduce itching and improve comfort, although itching in ICD is typically less severe than in allergic dermatitis.

2. Antibiotics:

- **Systemic antibiotics** (e.g., **flucloxacillin**) may be required if there is secondary bacterial infection (e.g., **impetigo**) due to scratching and skin breakdown.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Long-term use of topical corticosteroids** should be avoided, especially on thin skin areas (e.g., face, genitals), due to the risk of **skin atrophy** and **telangiectasia**.

b) Second-Line Therapy:

1. Phototherapy:

- **Narrowband UVB** may be useful in patients with chronic or recalcitrant irritant contact dermatitis.

2. Systemic therapy:

- **Oral corticosteroids**: Short courses of **prednisolone** may be considered for severe flares that do not respond to topical treatments.

8. Routine Monitoring and Follow-Up:

- **Monitoring of skin improvement**: Regular follow-up to assess the effectiveness of avoidance strategies and topical therapies.
- **Watch for secondary infections**: Any signs of infection (e.g., crusting, oozing) should prompt immediate treatment with antibiotics.
- **Evaluation of chronicity**: If the condition persists or worsens, further investigation may be necessary to rule out **occupational dermatitis** or other underlying conditions.

9. Complications:

1. Secondary bacterial infection:

- Irritant contact dermatitis can lead to **skin breakdown**, increasing the risk of infection with **Staphylococcus aureus** or **Streptococcus pyogenes**.

2. Chronic dermatitis:

- Repeated exposure to irritants or inadequate treatment can lead to **chronic dermatitis** with **lichenification**, **fissuring**, and **pigmentary changes**.

Summary of Key Points for Irritant Contact Dermatitis:

- **Irritant contact dermatitis** is caused by direct damage to the skin from exposure to irritants, and it does not involve an allergic reaction.
- Common symptoms include **redness**, **dryness**, **itching**, **burning**, and, in more severe cases, **blisters** or **cracking** of the skin.
- Management focuses on **avoiding the irritant**, using **emollients** to repair the skin barrier, and **topical corticosteroids** to control inflammation during acute flares.
- Long-term or severe cases may require **phototherapy** or **systemic therapy**.
- Regular monitoring and **early treatment of secondary infections** are important to prevent complications.

80. Allergic Contact Dermatitis

1. Detailed Definition of Allergic Contact Dermatitis (ACD):

Allergic contact dermatitis (ACD) is a type of **delayed-type hypersensitivity reaction (Type IV hypersensitivity)** caused by direct skin contact with an allergen. Unlike irritant contact dermatitis, ACD involves the **immune system** and requires prior sensitization to the allergen. Upon re-exposure, the immune response is triggered, resulting in inflammation, itching, and the development of eczematous lesions at the site of contact.

2. Common Presenting Complaints and Symptoms:

- **Erythema (Redness):** Redness at the site of allergen contact, often with well-demarcated borders.
- **Itching (Pruritus):** Intense itching, especially in acute reactions, which can lead to scratching and worsening of the condition.
- **Swelling:** The affected area may become edematous, especially in acute allergic reactions.
- **Papules and vesicles:** Small, raised bumps (papules) or fluid-filled blisters (vesicles) may appear on the skin. In severe cases, vesicles can burst, leading to **oozing** or **crusting**.
- **Scaling and cracking:** With chronic exposure, the skin may become dry, scaly, and develop fissures.
- **Lichenification:** Thickening of the skin due to chronic scratching or rubbing.

Common Sites Affected:

- **Hands:** From exposure to allergens like nickel, rubber, or cosmetics.
- **Face and eyelids:** From cosmetics, fragrances, or airborne allergens.
- **Earlobes and neck:** Often due to contact with jewelry (e.g., nickel sensitivity).
- **Feet:** From exposure to allergens in shoes or socks (e.g., rubber, leather chemicals).

3. First-Line Investigations:

a) Patch Testing:

- **Gold standard** for diagnosing allergic contact dermatitis.
- Small amounts of suspected allergens are applied to the skin under occlusive patches for **48 hours**. The patches are then removed, and the skin is examined for signs of an allergic reaction (erythema, swelling, papules).
- **Positive reactions:** Indicate the presence of a delayed hypersensitivity response to the allergen.

b) Clinical Examination:

- **Detailed patient history:** Key in identifying potential allergens, including occupational and recreational exposures.
- **Examine the pattern and distribution** of dermatitis: Lesions tend to be localized to the area of contact with the allergen.

c) Exclusion of Other Types of Dermatitis:

- **Exclusion of irritant contact dermatitis (ICD):** Based on history, as ICD typically occurs immediately after exposure to irritants and does not involve immune sensitization.

4. Explanation of Investigations:

- **Patch testing:** Essential for identifying the specific allergen causing the contact dermatitis. By isolating and avoiding the allergen, symptoms can often be controlled.
- **Clinical examination and history:** Crucial for determining the causative allergen and ruling out other potential causes of dermatitis.

5. Diagnosis Criteria for Allergic Contact Dermatitis:

Allergic contact dermatitis is diagnosed based on a combination of the following:

- **History of exposure** to a potential allergen.
- **Delayed onset of symptoms** after exposure (usually 24-72 hours after contact).
- **Positive patch test** for the allergen.
- **Resolution of symptoms** when the allergen is avoided.
- **Localized dermatitis** at the site of contact.

6. First-Line Therapy According to Guidelines:

The primary treatment for allergic contact dermatitis is **identifying and avoiding the allergen** and using topical therapies to control symptoms and inflammation.

a) General Measures:

1. **Avoidance of the allergen:**
 - Once the specific allergen has been identified through patch testing, complete avoidance is essential.
 - Patients should be educated on **hidden sources of allergens**, such as nickel in jewelry, latex in gloves, or preservatives in cosmetics.
2. **Emollients:**
 - **Regular application of emollients** helps to restore the skin barrier and alleviate dryness.
 - Creams and ointments (e.g., **petrolatum-based** emollients) are preferred.

b) Topical Therapies:

1. **Topical corticosteroids:**
 - **Low-potency corticosteroids** (e.g., **hydrocortisone 1%**) for mild cases or use on sensitive areas (e.g., face, genitals).
 - **Moderate to high-potency corticosteroids** (e.g., **betamethasone valerate 0.1%**) for more severe or widespread involvement.
 - **Short-term use** is preferred to minimize the risk of side effects, including skin thinning.
2. **Topical calcineurin inhibitors:**
 - **Tacrolimus** or **pimecrolimus** can be used as **steroid-sparing agents**, especially in chronic cases or for use on sensitive skin areas.
 - These agents inhibit T-cell activation, reducing inflammation without the risk of skin atrophy associated with steroids.

c) Oral Therapies:

1. **Oral antihistamines:**
 - May provide **symptomatic relief** of itching, especially during acute flares.
 - **Sedating antihistamines** (e.g., **hydroxyzine**) can help reduce itching at night and improve sleep.
2. **Oral corticosteroids:**
 - **Short courses of systemic corticosteroids** (e.g., **prednisolone**) may be necessary for **severe flares** or widespread allergic contact dermatitis.

- Prolonged use of systemic steroids should be avoided due to the risk of side effects (e.g., osteoporosis, diabetes).
3. **Antibiotics:**
- If there is evidence of **secondary bacterial infection** (e.g., **Staphylococcus aureus**), **oral antibiotics** such as **flucloxacillin** may be necessary.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Long-term use of potent topical corticosteroids** should be avoided due to the risk of **skin thinning, telangiectasia, and striae**.

b) Second-Line Therapy:

1. Phototherapy:

- **Narrowband UVB** or **PUVA (psoralen plus ultraviolet A)** therapy may be helpful for chronic or resistant cases of allergic contact dermatitis.

2. Systemic immunosuppressants:

- For **severe cases** unresponsive to topical therapies or phototherapy, **systemic immunosuppressants** such as **azathioprine, methotrexate, or ciclosporin** may be used under specialist guidance.

8. Routine Monitoring and Follow-Up:

- **Regular follow-up:** Ensures that the patient is effectively avoiding the identified allergen and monitors for improvement of dermatitis.
- **Monitor for side effects:** Especially in patients using topical corticosteroids or systemic therapies.
- **Patch testing:** May need to be repeated if the condition persists, or new allergens are suspected.

9. Complications:

1. Chronic dermatitis:

- Repeated exposure to allergens or inadequate treatment can lead to chronic dermatitis, with **lichenification, fissures, and persistent scaling**.

2. Secondary infection:

- Scratching and skin breakdown can predispose patients to secondary bacterial infections (e.g., impetigo) or viral infections (e.g., eczema herpeticum).

Summary of Key Points for Allergic Contact Dermatitis:

- **Allergic contact dermatitis** is an **immune-mediated delayed hypersensitivity** reaction to skin contact with specific allergens.
- Symptoms include **redness, intense itching, swelling, papules, and vesicles**, often localized to the site of contact.
- **Patch testing** is the gold standard for identifying the causative allergen.
- Treatment involves **avoiding the allergen**, using **emollients** to restore the skin barrier, and **topical corticosteroids** or **calcineurin inhibitors** to control inflammation.
- **Phototherapy** or **systemic immunosuppressants** may be required for chronic or resistant cases.
- **Monitoring** is important to ensure allergen avoidance and to manage potential complications like secondary infections.

81. Erythroderma

1. Detailed Definition of Erythroderma:

Erythroderma (also known as **exfoliative dermatitis**) is a severe, potentially life-threatening skin condition characterized by **generalized erythema** (redness) involving more than **90% of the body surface area**. It is often associated with **scaling** and **exfoliation** of the skin.

Erythroderma can occur as a primary condition or secondary to pre-existing skin diseases, drug reactions, or systemic diseases.

2. Common Presenting Complaints and Symptoms:

- **Diffuse erythema (redness):** The most prominent feature, involving nearly the entire skin surface.
- **Scaling and peeling:** The skin becomes dry, scaly, and may peel off in sheets.
- **Pruritus (itching):** Intense itching is a common symptom.
- **Fever and malaise:** Patients often present with systemic symptoms, including fatigue and fever, due to widespread inflammation and skin loss.
- **Oedema:** Swelling of the skin can occur due to fluid loss through the damaged skin barrier.
- **Hair loss:** Shedding of hair, particularly from the scalp, eyebrows, and body hair.
- **Nail changes:** Dystrophic nails, nail shedding, or loss of nails due to chronic inflammation.

Systemic Symptoms:

- **Hypothermia:** The loss of the skin barrier can impair thermoregulation, leading to low body temperature.
- **Fluid and electrolyte imbalances:** Loss of the skin barrier can lead to significant fluid and protein loss, leading to dehydration, hypoproteinaemia, and electrolyte abnormalities.
- **Secondary infections:** The damaged skin barrier increases susceptibility to bacterial, fungal, and viral infections.

3. First-Line Investigations:

a) Full Blood Count (FBC):

- **Leukocytosis:** Elevated white blood cell count may indicate an underlying infection or inflammation.
- **Anemia:** Can result from chronic inflammation or nutritional deficiencies due to impaired skin function.

b) Electrolytes and Renal Function:

- **Electrolyte disturbances:** Sodium and potassium levels may be abnormal due to fluid loss.
- **Renal function:** Dehydration and hypovolemia can lead to impaired kidney function.

c) Liver Function Tests:

- **Hypoalbuminemia:** Due to loss of proteins through the skin or as a result of chronic inflammation.

d) Skin Biopsy:

- **Definitive diagnostic tool:** A skin biopsy is essential to determine the underlying cause of erythroderma, whether it is related to pre-existing skin conditions (e.g., psoriasis, eczema), drug reactions, or other systemic diseases (e.g., cutaneous T-cell lymphoma).

e) Blood Cultures:

- Performed if there are signs of systemic infection or sepsis.

f) Chest X-ray:

- To exclude underlying malignancies (e.g., lymphoma) or associated pulmonary complications.

4. Explanation of Investigations:

- **Full Blood Count (FBC):** Assesses the patient's overall health, identifies infection (leukocytosis), and checks for anaemia, which can result from chronic inflammation.
- **Electrolytes and renal function:** Evaluates the impact of fluid loss on the body's salt balance and kidney function.
- **Skin biopsy:** Identifies the underlying cause of erythroderma, which is critical in determining treatment. Histopathology can reveal whether the condition is due to psoriasis, eczema, drug reactions, or other skin diseases.
- **Blood cultures:** Rule out sepsis or secondary bacterial infections in patients with widespread skin damage.

5. Diagnosis Criteria for Erythroderma:

Erythroderma is diagnosed based on clinical presentation and laboratory findings:

- **Redness and scaling** involving **90% or more** of the skin surface.
- **Systemic symptoms:** Including fever, malaise, and electrolyte imbalances.
- **Underlying cause identification:** A skin biopsy may be required to identify the underlying condition responsible for erythroderma.

6. First-Line Therapy According to Guidelines:

Management of erythroderma focuses on **stabilizing the patient**, treating the **underlying cause**, and **preventing complications** such as fluid loss, infections, and electrolyte disturbances.

a) Hospitalization:

- **Erythroderma is a medical emergency**, and patients typically require **inpatient care**, often in an intensive care unit (ICU) or high-dependency unit (HDU), for monitoring and supportive treatment.

b) General Supportive Measures:

1. **Fluid and electrolyte management:**
 - Intravenous fluids may be necessary to maintain hydration and correct electrolyte imbalances.
 - Monitor urine output to assess kidney function.
2. **Temperature regulation:**
 - Keep the patient warm to prevent **hypothermia**, as the damaged skin cannot effectively regulate body temperature.
3. **Nutritional support:**
 - **High-protein diet** to compensate for protein loss through the skin and to support healing.
 - **Parenteral nutrition** may be required in severe cases.
4. **Infection control:**
 - **Topical antibiotics** or **oral antibiotics** should be administered if secondary bacterial infections are present.

- **Antifungal or antiviral therapies** may be required if there are signs of fungal or viral infections.

c) Specific Therapies:

1. Topical corticosteroids:

- Potent **topical steroids** (e.g., **betamethasone 0.1%**) are often used to reduce inflammation and skin irritation.
- **Emollients**: Regular application of emollients helps maintain skin hydration and restore the skin barrier.

2. Systemic corticosteroids:

- **Oral corticosteroids** (e.g., **prednisolone**) may be necessary for patients with severe inflammation, particularly in cases where drug reactions or autoimmune diseases are the cause.

3. Treatment of underlying conditions:

- **Psoriasis**: Treat with **systemic agents** such as **methotrexate**, **cyclosporin**, or **biologic agents** (e.g., **TNF-alpha inhibitors**).
- **Cutaneous T-cell lymphoma**: Manage with **systemic chemotherapy** or **radiotherapy**.
- **Drug-induced erythroderma**: Immediate **discontinuation of the offending drug** is crucial.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Long-term corticosteroid use**: Should be avoided if possible due to the risk of side effects, including immunosuppression, hyperglycaemia, and osteoporosis.

b) Second-Line Therapy:

1. Immunosuppressants:

- **Ciclosporin**: Often used in severe cases of erythroderma caused by psoriasis or eczema that does not respond to corticosteroids.
- **Methotrexate**: May be used for erythroderma secondary to psoriasis or cutaneous lymphoma.

2. Biologic agents:

- **TNF-alpha inhibitors** or **IL-17 inhibitors** may be considered for patients with **psoriatic erythroderma**.

8. Routine Monitoring and Follow-Up:

- **Frequent monitoring of fluid status and electrolyte levels** is crucial due to the risk of dehydration and electrolyte imbalances.
- **Regular skin assessments**: To monitor for secondary infections and the healing progress of the skin.
- **Biopsy follow-up**: If a skin biopsy was performed, follow-up on histopathological results to ensure correct diagnosis and treatment of the underlying cause.

9. Complications:

1. Infection:

- Loss of the skin barrier increases the risk of secondary bacterial, viral, and fungal infections. Sepsis is a life-threatening complication.

2. Fluid and electrolyte imbalance:

- Loss of fluids and electrolytes through the skin can lead to dehydration, hypovolemia, and renal impairment.
- 3. **Cardiac failure:**
 - Severe erythroderma can lead to **high-output cardiac failure** due to the increased metabolic demands of the skin.
- 4. **Hypothermia:**
 - Due to the impaired ability of the skin to regulate body temperature.
- 5. **Nutritional deficiencies:**
 - Protein and calorie loss through the damaged skin can lead to **malnutrition** and **weight loss**.

Summary of Key Points for Erythroderma:

- **Erythroderma** is a serious, potentially life-threatening condition involving generalized erythema and scaling of more than **90% of the body surface area**.
- **Common causes** include psoriasis, eczema, drug reactions, and cutaneous lymphoma.
- **Management requires hospitalization**, supportive care (fluid and electrolyte management, temperature regulation), and treatment of the underlying cause.
- **Skin biopsy** is often needed to confirm the diagnosis, and systemic steroids or immunosuppressants may be required in severe cases.
- **Regular monitoring** for infections, fluid balance, and electrolyte status is crucial to prevent complications such as sepsis and renal failure.

82. Other Types of Eczema (Dermatitis)

Eczema, also known as **dermatitis**, encompasses a range of skin conditions characterized by inflammation, redness, and itching. Besides **atopic dermatitis** and **contact dermatitis**, there are several other common types of eczema, each with distinct causes and presentations.

1. Seborrheic Dermatitis

a) Definition:

Seborrheic dermatitis is a chronic, relapsing form of eczema that primarily affects areas rich in sebaceous (oil) glands, such as the scalp, face, and upper trunk. It is associated with the overgrowth of **Malassezia** yeast and affects both infants and adults.

b) Common Presenting Complaints and Symptoms:

- **Greasy, yellow scales** on red, inflamed skin.
- **Dandruff:** Flaky scales on the scalp.
- **Itching:** May vary in intensity, but tends to be mild.
- **Affects oily areas:** Common on the scalp, eyebrows, nasolabial folds, ears, and upper chest.
- **Cradle cap:** In infants, seborrheic dermatitis may present as thick, yellow, greasy scales on the scalp.

c) First-Line Investigations:

- **Clinical diagnosis:** Based on appearance and distribution of the rash. Investigations are rarely needed.
- **Consider fungal swab:** To rule out tinea capitis or other scalp infections.

d) Management:

1. **Topical antifungals:**
 - **Ketoconazole** 2% shampoo or cream: Reduces *Malassezia* yeast overgrowth.
2. **Topical corticosteroids:**

- Mild corticosteroids (e.g., **hydrocortisone 1%**) for short-term use in areas of inflammation.
- 3. **Medicated shampoos:**
 - **Selenium sulfide, zinc pyrithione, or coal tar** shampoos to control scalp flaking and reduce yeast.

2. Nummular Eczema (Discoid Eczema)

a) Definition:

Nummular eczema, or discoid eczema, is a chronic skin condition characterized by **coin-shaped** (nummular) patches of eczema. The cause is often unknown but may be linked to **dry skin** or environmental triggers.

b) Common Presenting Complaints and Symptoms:

- **Circular, well-demarcated patches** of red, itchy, and scaly skin.
- **Oozing and crusting** can occur in acute lesions.
- Commonly affects the **extremities**, particularly the legs and forearms.
- **Intense itching** is a hallmark symptom.

c) First-Line Investigations:

- **Clinical diagnosis:** Based on the characteristic round or oval patches.
- **Patch testing:** May be performed if allergic contact dermatitis is suspected as a trigger.

d) Management:

1. **Emollients:**
 - Regular use of **thick moisturizers** to prevent skin dryness.
2. **Topical corticosteroids:**
 - **Moderate to high-potency corticosteroids** (e.g., **betamethasone valerate 0.1%**) are often required to reduce inflammation.
3. **Antibiotics:**
 - **Oral antibiotics** (e.g., **flucloxacillin**) may be needed if secondary bacterial infection is present.

3. Dyshidrotic Eczema (Pompholyx)

a) Definition:

Dyshidrotic eczema, also known as **pompholyx,** is characterized by **itchy vesicles** (small fluid-filled blisters) that appear on the hands and feet. The exact cause is unclear, but stress, allergies, and irritants are common triggers.

b) Common Presenting Complaints and Symptoms:

- **Small, itchy vesicles:** Affecting the sides of the fingers, palms, and soles.
- **Severe itching:** Often the first symptom, followed by the appearance of vesicles.
- **Cracked skin:** The vesicles may burst, leading to painful skin cracks and fissures.
- **Scaling and peeling:** Occurs as the vesicles heal.

c) First-Line Investigations:

- **Clinical diagnosis:** Based on the characteristic vesicular eruption.
- **Patch testing:** May be performed to exclude allergic contact dermatitis.

d) Management:

1. **Topical corticosteroids:**
 - **High-potency corticosteroids** (e.g., **clobetasol propionate**) to reduce vesicular inflammation.
2. **Cold compresses:**
 - To soothe itching and reduce inflammation.

3. Barrier creams:

- To protect the skin from irritants and reduce flare-ups.

4. Stasis Dermatitis (Venous Eczema)

a) Definition:

Stasis dermatitis is a form of eczema that occurs in the lower legs due to **chronic venous insufficiency** (poor blood flow in the veins). It is commonly seen in older adults with **varicose veins** or a history of **deep vein thrombosis**.

b) Common Presenting Complaints and Symptoms:

- **Red or brown patches** on the lower legs and ankles.
- **Swelling (oedema)**: The legs may be swollen, particularly at the end of the day.
- **Scaling and itching**: The skin may become dry, itchy, and cracked.
- **Ulceration**: Chronic stasis dermatitis can lead to the development of venous leg ulcers.

c) First-Line Investigations:

- **Doppler ultrasound**: To assess for venous insufficiency or venous thromboembolism.
- **Clinical examination**: Based on the presence of venous disease and eczema in the lower legs.

d) Management:

1. Compression stockings:

- **Graduated compression stockings** help improve venous return and reduce leg swelling.

2. Topical corticosteroids:

- **Mild to moderate corticosteroids** (e.g., **hydrocortisone 1%**) to reduce inflammation.

3. Emollients:

- Frequent use of moisturizers to maintain skin hydration and prevent scaling.

5. Asteatotic Eczema (Eczema Craquelé)

a) Definition:

Asteatotic eczema (also called **eczema craquelé**) is a type of eczema that occurs due to **excessive dryness** of the skin. It is more common in elderly individuals and is often triggered by **cold weather**, **low humidity**, or excessive **hot showers**.

b) Common Presenting Complaints and Symptoms:

- **Dry, cracked skin**: The skin takes on a characteristic "**cracked porcelain**" or "**crazy paving**" appearance.
- **Itching**: Mild to moderate itching is common.
- Commonly affects the **lower legs**, particularly in elderly individuals.

c) First-Line Investigations:

- **Clinical diagnosis**: Based on the dry, cracked appearance of the skin and the presence of pruritus.

d) Management:

1. Emollients:

- **Frequent use of moisturizers** with high oil content (e.g., **petroleum-based** or **urea-based** creams) to hydrate the skin.

2. Avoidance of irritants:

- Avoid **hot showers** and **harsh soaps**, which exacerbate dryness.

3. Topical corticosteroids:

- **Mild corticosteroids** (e.g., **hydrocortisone 1%**) for short-term use in areas of inflammation.

6. Lichen Simplex Chronicus (Neurodermatitis)

a) Definition:

Lichen simplex chronicus is a form of chronic eczema caused by **repeated scratching or rubbing** of the skin, leading to **lichenification** (thickened skin). It is often triggered by an underlying condition, such as **atopic dermatitis** or **contact dermatitis**.

b) Common Presenting Complaints and Symptoms:

- **Thickened, scaly skin:** The skin appears **leathery** and hyperpigmented due to chronic scratching.
- **Intense itching:** Patients feel compelled to scratch the affected area, worsening the condition.
- Commonly affects the **neck, scalp, wrists, ankles, and genital areas**.

c) First-Line Investigations:

- **Clinical diagnosis:** Based on the characteristic appearance and the history of chronic scratching.

d) Management:

1. **Topical corticosteroids:**
 - **High-potency corticosteroids** to reduce inflammation and itch.
2. **Antihistamines:**
 - To reduce itching, particularly at night.
3. **Behavioral modification:**
 - **Stopping the scratch-itch cycle** is critical, often requiring patient education and support.

Summary of Key Points for Other Types of Eczema:

- **Seborrheic dermatitis:** Greasy scales in oily areas; managed with antifungals and mild corticosteroids.
- **Nummular eczema:** Circular patches of eczema, often on the legs and arms; managed with emollients and corticosteroids

83. Melanoma

1. Detailed Definition of Melanoma:

Melanoma is a type of skin cancer that arises from the **malignant transformation of melanocytes**, the pigment-producing cells found in the epidermis. It is the most dangerous form of skin cancer due to its high potential for **metastasis** (spreading to other parts of the body). Although melanoma is less common than basal cell carcinoma or squamous cell carcinoma, it accounts for the majority of skin cancer-related deaths.

2. Common Presenting Complaints and Symptoms:

- **Change in a mole:** The most common presentation of melanoma. Patients may notice changes in a mole's **size, shape, colour, or symmetry**.
- **New pigmented lesion:** Development of a new mole or dark spot on the skin in adulthood.
- **Itching, tenderness, or bleeding:** A mole or lesion that becomes itchy, tender, or starts to bleed can indicate melanoma.
- **Ulceration:** Advanced melanoma may ulcerate or form open sores.

- **Asymmetry:** Irregularity in the shape of the lesion.
- **Colour variation:** The lesion may contain multiple colors, such as shades of brown, black, red, white, or blue.
- **Enlarging lesion:** A mole that grows in diameter, particularly one larger than 6 mm (about the size of a pencil eraser), is a concern.

Common Sites Affected:

- **Sun-exposed areas:** Most melanomas occur on sun-exposed areas, such as the back, legs, arms, and face.
- **Acral locations:** In people with darker skin, melanomas often occur on the **palms**, **soles**, and **under the nails** (acral lentiginous melanoma).

3. First-Line Investigations:

a) Clinical Examination:

- **ABCDE criteria:** This is the primary tool used for the early detection of melanoma:
 - **A: Asymmetry** – One half of the mole does not match the other.
 - **B: Border** – Irregular, scalloped, or poorly defined borders.
 - **C: Colour** – Variation in colour, including different shades of brown, black, tan, and sometimes white, red, or blue.
 - **D: Diameter** – Lesions greater than 6 mm in diameter are more suspicious, but melanomas can be smaller.
 - **E: Evolving** – Changes in size, shape, or colour over time.

b) Dermoscopy:

- **Dermoscopy** (also known as epiluminescence microscopy): A non-invasive tool used to examine pigmented skin lesions. It provides a magnified view, allowing for better visualization of specific features associated with melanoma, such as **asymmetrical pigmentation** and **atypical network structures**.

c) Excisional Biopsy:

- **Gold standard for diagnosis:** If melanoma is suspected, an **excisional biopsy** should be performed, where the entire lesion is removed along with a margin of normal skin. The tissue is then examined under a microscope to confirm the diagnosis and determine the depth of invasion.

d) Lymph Node Examination:

- **Palpation of regional lymph nodes:** As melanoma metastasizes through lymphatic channels, enlarged lymph nodes may indicate spread.

4. Explanation of Investigations:

- **Dermoscopy:** Allows for a detailed view of a lesion's structure, helping to differentiate benign moles from melanoma.
- **Excisional biopsy:** Determines the histological type of melanoma, its **Breslow thickness** (depth of invasion), and presence of **ulceration**, all of which are important prognostic factors.
- **Sentinel lymph node biopsy:** Performed in certain cases to check for the spread of melanoma to regional lymph nodes.

5. Diagnosis Criteria for Melanoma:

Melanoma is diagnosed based on the **histopathological findings** from the excisional biopsy. The key features include:

- **Atypical melanocytes:** Melanocytes that appear abnormal under the microscope.

- **Breslow thickness:** The depth of melanoma invasion into the skin, measured in millimeters from the top layer of the skin to the deepest point of the tumour. A higher Breslow thickness is associated with a worse prognosis.
- **Ulceration:** The presence of an ulcerated surface is another negative prognostic factor.
- **Mitotic rate:** A measure of how quickly the melanoma cells are dividing. A higher mitotic rate suggests more aggressive growth.

6. First-Line Therapy According to Guidelines:

The management of melanoma depends on the **stage of the disease** at diagnosis.

a) Surgical Excision:

1. Wide local excision:

- Once melanoma is diagnosed via biopsy, the standard treatment is a **wide local excision** of the tumour. The goal is to remove the melanoma along with a margin of normal tissue to ensure complete removal.
- The size of the surgical margin depends on the **Breslow thickness**:
 - **In situ melanoma:** 0.5 cm margin.
 - **Melanomas ≤ 1 mm thick:** 1 cm margin.
 - **Melanomas 1-2 mm thick:** 1-2 cm margin.
 - **Melanomas > 2 mm thick:** 2 cm margin.

b) Sentinel Lymph Node Biopsy:

- For **melanomas > 1 mm thick**, or if there is ulceration, a **sentinel lymph node biopsy** (SLNB) is recommended to determine if cancer has spread to the lymph nodes. Positive sentinel lymph node involvement may lead to further surgery or adjuvant treatment.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Surgery:

- **Advanced metastatic disease:** Surgery may not be an option if the melanoma has spread to distant organs. In these cases, systemic treatments become the mainstay of therapy.

b) Second-Line Therapy:

1. Immunotherapy:

- **Checkpoint inhibitors** (e.g., **nivolumab**, **pembrolizumab**) are commonly used in **advanced or metastatic melanoma**. These drugs target immune checkpoints, helping the body's immune system attack cancer cells.

2. Targeted Therapy:

- For patients with a **BRAF mutation** (about 50% of melanomas), **BRAF inhibitors** (e.g., **vemurafenib**, **dabrafenib**) combined with **MEK inhibitors** (e.g., **trametinib**) are effective in shrinking tumours.

3. Chemotherapy:

- **Dacarbazine** was traditionally used, but chemotherapy is now less common in the era of immunotherapy and targeted therapy due to better efficacy and survival outcomes with newer treatments.

4. Radiotherapy:

- Can be used for **palliative care** in patients with brain metastases or to control local disease in certain cases.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** Patients who have been treated for melanoma require lifelong follow-up due to the risk of recurrence or development of new melanomas.
 - Follow-up intervals depend on the stage of melanoma but generally involve **dermatological examinations** every 3 to 6 months for the first few years, then annually.
- **Self-examination:** Patients should be educated to monitor their skin for new lesions or changes in existing moles.
- **Imaging:** For higher-stage melanomas, routine imaging (e.g., **CT** or **PET scans**) may be used to check for metastasis during follow-up.

9. Complications:

1. **Metastasis:**
 - Melanoma can spread to the **lymph nodes, lungs, liver, brain, and bones**, leading to significant morbidity and mortality.
2. **Recurrence:**
 - Local recurrence of melanoma is possible even after surgical excision, especially in thicker or ulcerated melanomas.
3. **Lymphedema:**
 - Following lymph node dissection, patients may develop **lymphedema**, particularly in the limbs.
4. **Secondary skin cancers:**
 - Patients with a history of melanoma are at higher risk for developing new melanomas or other types of skin cancer.
 -

Summary of Key Points for Melanoma:

- **Melanoma** is a malignant tumour arising from **melanocytes** and is highly aggressive with the potential to metastasize.
- **ABCDE criteria** help in early detection: **Asymmetry, Border irregularity, Colour variation, Diameter > 6 mm, Evolving lesion**.
- **Excisional biopsy** followed by **wide local excision** is the primary treatment for early-stage melanoma.
- **Immunotherapy** and **targeted therapies** have revolutionized the treatment of advanced melanoma, significantly improving survival rates.
- **Regular follow-up** and **skin monitoring** are crucial to detect recurrence or the development of new melanomas.

84. Squamous Cell Carcinoma (SCC)

1. Detailed Definition of Squamous Cell Carcinoma (SCC):

Squamous cell carcinoma (SCC) is a common type of **non-melanoma skin cancer** that arises from the **keratinocytes** of the epidermis, the outer layer of the skin. SCC is more aggressive than **basal cell carcinoma (BCC)** and has a higher risk of **local invasion** and **metastasis**, especially in high-risk locations like the lips, ears, and genitalia. SCC typically occurs on **sun-exposed areas** of the body and is most common in individuals with **cumulative UV radiation exposure**.

2. Common Presenting Complaints and Symptoms:

- **Scaly, crusted lesions:** SCC often appears as a **scaly patch** or **plaque** with a **rough surface**.
- **Non-healing ulcers:** SCC can present as a **non-healing ulcer** or **sore** that bleeds or crusts.
- **Firm, red nodules:** Some SCCs appear as a raised, **firm nodule** that may ulcerate.
- **Tenderness or pain:** Lesions may be tender or painful, especially as they grow.
- **Bleeding or oozing:** Advanced SCC may bleed, ooze, or form a crust.
- **Rapid growth:** Lesions may grow quickly compared to **basal cell carcinoma**, which tends to grow slowly.

Common Sites Affected:

- **Sun-exposed areas:** The face, scalp, ears, neck, hands, forearms, and lower lips are the most commonly affected areas.
- **Mucosal surfaces:** SCC can occur on mucosal surfaces, such as the mouth, lips, and genitalia.
- **Scars or areas of chronic inflammation:** SCC may develop in areas of chronic scarring (e.g., from burns) or chronic wounds.

3. First-Line Investigations:

a) Clinical Examination:

- **Full skin examination:** A thorough examination of the skin, including high-risk areas such as the face, scalp, ears, and hands, is essential. Assess for any signs of a non-healing, scaly, or ulcerated lesion.
- **Lymph node palpation:** Regional lymph nodes should be palpated to check for metastasis, particularly in advanced cases.

b) Skin Biopsy:

- **Punch biopsy or excisional biopsy:** This is the **gold standard** for confirming the diagnosis of SCC. The biopsy will assess:
 - The **depth of invasion**.
 - The **differentiation** of the cells (well-differentiated, moderately differentiated, or poorly differentiated).
 - Presence of **perineural invasion** (involvement of nerves), which can indicate more aggressive behavior.

c) Dermoscopy:

- **Dermoscopy:** A non-invasive tool used to examine the lesion's vascular and structural patterns. It can help differentiate SCC from other skin conditions, though a biopsy is always required for definitive diagnosis.

d) Imaging:

- **Ultrasound or CT scan** may be required to assess the extent of local invasion or involvement of lymph nodes in advanced or high-risk SCC.

4. Explanation of Investigations:

- **Skin biopsy:** Provides a definitive diagnosis by assessing the **histological appearance** of the tumour, including its **degree of differentiation**, **depth of invasion**, and the presence of **perineural or vascular invasion**.
- **Dermoscopy:** Helps evaluate structural patterns to differentiate SCC from other skin cancers or benign lesions.
- **Lymph node examination:** Palpation and imaging (e.g., ultrasound) are used to detect metastasis to regional lymph nodes.

5. Diagnosis Criteria for Squamous Cell Carcinoma:

Diagnosis is confirmed based on the **histopathological findings** from a biopsy. The key features include:

- **Atypical keratinocytes:** Large, abnormal cells with increased mitotic activity, originating from the **squamous cell layer** of the epidermis.
- **Invasion of the dermis:** The presence of tumour cells invading beyond the basement membrane into the dermis or deeper structures.
- **Differentiation:** SCC can be classified as:
 - **Well-differentiated** (resembles normal squamous cells).
 - **Moderately differentiated.**
 - **Poorly differentiated** (more aggressive, with less resemblance to normal squamous cells).

6. First-Line Therapy According to Guidelines:

a) Surgical Excision:

1. **Wide local excision:**
 - The mainstay of treatment is **surgical excision** with **clear margins**. The margin size depends on the size and location of the lesion:
 - **Low-risk SCC:** A **4 mm margin** of normal skin around the lesion.
 - **High-risk SCC** (e.g., poorly differentiated, deep, or recurrent lesions): A **6 mm margin** or more may be required.
2. **Mohs micrographic surgery:**
 - **Mohs surgery** is often recommended for **high-risk SCCs**, particularly in cosmetically sensitive areas (e.g., face, ears, nose) or in cases of **recurrent SCC**. This technique allows for **layer-by-layer excision** with immediate histological examination, ensuring complete removal with minimal tissue loss.

b) Curettage and Electrodessication:

- Suitable for **small, well-differentiated SCCs** in low-risk areas. It involves scraping off the lesion with a curette followed by electrodessication (heat application) to destroy remaining cancer cells.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Surgery:

- Surgery may be contraindicated in patients with poor **functional status** or those who are not suitable for anaesthesia due to comorbidities.

b) Second-Line Therapy:

1. **Radiotherapy:**
 - Used for **non-surgical candidates** or patients with **inoperable tumours**. It may also be used as **adjuvant therapy** after surgery if the SCC is high risk (e.g., positive margins, perineural invasion).
2. **Systemic Therapy:**
 - For **metastatic** or **locally advanced SCC**, **immunotherapy** with **checkpoint inhibitors** (e.g., **cemiplimab**, an anti-PD-1 agent) can be effective.
3. **Cryotherapy:**
 - **Liquid nitrogen** can be used to freeze and destroy small, superficial SCCs, but it is typically reserved for early-stage or in situ SCCs (Bowen's disease).
4. **Topical therapy:**

- **5-fluorouracil (5-FU)** or **imiquimod** cream may be used for **superficial SCCs**, though it is less commonly used in invasive cases.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** SCC patients require regular follow-up visits every 3 to 6 months for at least the first 2 years to monitor for recurrence or development of new skin cancers.
- **Self-examination:** Patients should be educated on the importance of self-monitoring for new or changing skin lesions.
- **Lymph node assessment:** During follow-up, examination of regional lymph nodes is crucial for detecting metastasis.
- **Imaging:** For high-risk patients, periodic **imaging studies** (e.g., CT scans or ultrasound) may be performed to check for metastasis.

9. Complications:

1. **Local invasion:**
 - SCC can invade surrounding tissues, particularly when it arises on the **ears**, **lips**, or **genitals**, potentially leading to significant tissue destruction.
2. **Metastasis:**
 - Although less common than melanoma, SCC has a higher risk of metastasis compared to BCC. **Lymph nodes**, **lungs**, and **liver** are common sites of metastasis.
3. **Recurrence:**
 - Even after surgical excision, SCC may recur, especially if **inadequate margins** were obtained or if the SCC was poorly differentiated.

Summary of Key Points for Squamous Cell Carcinoma:

- **Squamous cell carcinoma (SCC)** is a common form of **non-melanoma skin cancer**, arising from **keratinocytes** and typically occurring in **sun-exposed areas**.
- It presents as a **scaly patch**, **crusted lesion**, or **non-healing ulcer**.
- **Surgical excision** with appropriate margins is the primary treatment, with **Mohs micrographic surgery** reserved for high-risk or cosmetically sensitive cases.
- **Radiotherapy**, **immunotherapy**, and **systemic treatments** are options for non-surgical candidates or patients with advanced SCC.
- Regular **follow-up and monitoring** for recurrence or metastasis are critical.

85. Basal Cell Carcinoma (BCC)

1. Detailed Definition of Basal Cell Carcinoma (BCC):

Basal cell carcinoma (BCC) is the most common form of **skin cancer** and originates from the **basal cells** in the epidermis. BCC is typically **slow-growing** and **locally invasive**, with a very low risk of metastasis. It is most commonly caused by **cumulative UV radiation exposure** and occurs predominantly in **sun-exposed areas** of the body. Despite its low metastatic potential, BCC can cause significant local tissue destruction if not treated.

2. Common Presenting Complaints and Symptoms:

- **Pearly or translucent nodule:** The most common form of BCC is a **flesh-coloured** or **pink nodule** with a **pearly or translucent appearance**.
- **Rolled borders:** The edges of the lesion often appear **rolled** or **raised**.

- **Telangiectasia:** Small, visible blood vessels (telangiectasia) may be present on the surface of the lesion.
- **Central ulceration:** As the tumour grows, it may develop **central ulceration** or form a **crater** with a **rolled edge**, often referred to as a **rodent ulcer**.
- **Slow growth:** BCC lesions tend to grow slowly over months to years.
- **Non-healing sore:** Patients may present with a **non-healing sore** that bleeds, crusts, or scabs over, especially on **sun-exposed areas**.

Common Sites Affected:

- **Sun-exposed areas:** The face (particularly the **nose, ears, and eyelids**), neck, scalp, shoulders, and back are most commonly affected.
- **Other high-risk areas:** The upper chest, arms, and hands are also frequently involved.

3. First-Line Investigations:

a) Clinical Examination:

- **Full skin examination:** A thorough examination of the skin is essential, focusing on the **face, scalp, ears, neck**, and other sun-exposed areas. The presence of a **pearly nodule, rolled borders**, or **telangiectasia** raises suspicion for BCC.

b) Dermoscopy:

- **Dermoscopy:** A non-invasive tool used to enhance visualization of the lesion's surface and deeper structures. Features suggestive of BCC include **arborizing telangiectasia, blue-gray ovoid nests**, and **leaf-like structures**.

c) Skin Biopsy:

- **Punch biopsy or excisional biopsy:** A skin biopsy is the **gold standard** for diagnosing BCC. The biopsy should include both the **tumour and adjacent normal skin** to assess the **type of BCC**, depth of invasion, and **margins**.

4. Explanation of Investigations:

- **Dermoscopy:** Helps visualize structures like **arborizing vessels, blue-gray globules**, and **peripheral pigmentation**, which can differentiate BCC from other skin cancers.
- **Skin biopsy:** Confirms the diagnosis by identifying **basaloid cells** and determining whether the BCC is **superficial, nodular**, or **infiltrative**. The type of BCC impacts treatment decisions.

5. Diagnosis Criteria for Basal Cell Carcinoma:

BCC is diagnosed based on clinical findings and confirmed by **histopathology** from a biopsy.

Key histopathological features include:

- **Basaloid cells:** Small, round, or oval cells with large nuclei resembling basal cells of the epidermis.
- **Peripheral palisading:** The basaloid cells may align peripherally in a **palisade** formation.
- **Invasion into the dermis:** BCC invades the **dermis** but typically does not metastasize beyond the local area.
- **Subtypes:** The most common subtypes include:
 - **Nodular BCC:** The most frequent, presenting as a pearly nodule with telangiectasia.
 - **Superficial BCC:** Presents as erythematous, scaly plaques, often misdiagnosed as eczema or psoriasis.
 - **Infiltrative or Morpheaform BCC:** More aggressive, presenting as a firm, ill-defined plaque with a higher potential for local invasion.

6. First-Line Therapy According to Guidelines:

a) Surgical Excision:

1. Wide local excision:

- **Surgical excision** with clear margins is the **mainstay of treatment** for BCC. The recommended margins depend on the subtype and location of the BCC:
 - **Low-risk BCC:** A **3-4 mm margin** of normal skin around the lesion.
 - **High-risk BCC:** A **5 mm or larger margin** may be necessary.

2. Mohs micrographic surgery:

- **Mohs surgery** is often indicated for **high-risk BCC**, such as those on the face (nose, eyelids, ears) or recurrent BCC. This technique allows **layer-by-layer excision** with immediate histological analysis of each layer, ensuring the tumour is completely removed while sparing healthy tissue.

b) Curettage and Electrodesiccation:

- This procedure involves **scraping** off the lesion with a curette and using **electrodesiccation** to destroy remaining tumour cells. It is suitable for **superficial or small nodular BCCs** but less effective for infiltrative or recurrent BCC.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Surgery:

- Surgery may be contraindicated in patients with **multiple comorbidities**, advanced age, or where surgery would cause significant cosmetic or functional impairment.

b) Second-Line Therapy:

1. Radiotherapy:

- **Radiotherapy** can be used as an alternative to surgery, particularly in older adults or patients unable to tolerate surgery. It is also used for **large BCCs**, **incompletely excised BCCs**, or tumours in **difficult-to-operate** areas.

2. Topical Therapy:

- **5-fluorouracil (5-FU):** Used for **superficial BCC**, applied topically to treat localized tumours.
- **Imiquimod cream:** A **topical immunomodulator** that stimulates the immune system to attack the cancer cells. Effective in **superficial BCC**.

3. Photodynamic Therapy (PDT):

- **PDT** involves applying a photosensitizing agent to the lesion and activating it with light to destroy the tumour. This treatment is useful for **superficial BCC** and cosmetically sensitive areas but is not suitable for deeper or nodular BCC.

4. Systemic Therapy:

- For **advanced or metastatic BCC** (rare), targeted therapies like **vismodegib** or **sonidegib** (hedgehog pathway inhibitors) are available.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** BCC patients require long-term follow-up due to the risk of recurrence and the development of new skin cancers.
 - Follow-up intervals may range from **6 to 12 months** depending on the patient's risk factors.
- **Self-examination:** Patients should be educated to perform regular self-examinations to detect any new or recurring lesions.
- **Imaging:** For **high-risk BCC**, periodic **imaging** may be needed to check for local recurrence or progression.

9. Complications:

1. Local tissue invasion:

- While BCC is generally slow-growing, it can cause **extensive local tissue destruction** if left untreated. BCC can invade into **bone, cartilage**, or other deep tissues, particularly on the face (e.g., **nasal BCC**).

2. Recurrence:

- Incomplete excision** or treating high-risk BCC with inadequate margins can lead to recurrence.

3. Cosmetic and functional impairment:

- BCC on the face or other visible areas can cause significant **cosmetic deformities**, particularly if surgery is delayed or extensive.

4. Metastasis (rare):

- While BCC rarely metastasizes, advanced cases of **aggressive subtypes** (e.g., infiltrative or morpheaform BCC) can metastasize to lymph nodes or distant organs, though this is extremely uncommon.

Summary of Key Points for Basal Cell Carcinoma:

- Basal cell carcinoma (BCC)** is the **most common skin cancer**, originating from **basal cells** of the epidermis and commonly found on **sun-exposed areas**.
- Nodular BCC** is the most common subtype, presenting as a **pearly nodule** with **rolled borders** and **telangiectasia**.
- Surgical excision** with appropriate margins is the primary treatment, with **Mohs micrographic surgery** reserved for high-risk or recurrent BCC.
- Radiotherapy, topical therapies, and systemic therapies** are alternatives for patients who are not suitable for surgery or for those with **superficial BCC**.
- Regular **monitoring and follow-up** are essential, as patients with a history of BCC are at increased risk of

86. Actinic Keratosis (AK)

1. Detailed Definition of Actinic Keratosis (AK):

Actinic keratosis (AK), also known as **solar keratosis**, is a **pre-cancerous skin lesion** caused by **chronic sun exposure**. AKs are formed due to **ultraviolet (UV) radiation-induced damage** to **keratinocytes** in the epidermis, leading to **dysplastic** (abnormal) changes. While AKs are benign, they have the potential to progress to **squamous cell carcinoma (SCC)**. Therefore, they are considered markers of sun damage and indicators of increased skin cancer risk.

2. Common Presenting Complaints and Symptoms:

- Rough, scaly patches:** The hallmark of AK is a **rough, dry, scaly patch** or plaque on sun-exposed areas of the skin.
- Erythema (redness):** The lesion may appear red or pink, though some AKs are **skin-coloured** or **brown**.
- Tenderness or pain:** In some cases, AKs can become tender, painful, or inflamed.
- Itching or burning sensation:** The affected area may become itchy or have a burning feeling.
- Bleeding or crusting:** Advanced or irritated lesions may bleed, crust over, or ulcerate.

Common Sites Affected:

- **Sun-exposed areas:** The most common areas for AKs include the **face, scalp, ears, forearms, backs of the hands, neck,** and **lower legs** in people who frequently expose these areas to sunlight.
- **Scalp:** In bald individuals, the scalp is a particularly vulnerable site.

3. First-Line Investigations:

a) Clinical Examination:

- **Full skin examination:** A thorough examination of the skin is critical, focusing on areas frequently exposed to the sun. The lesion typically feels **rough to the touch**, like **sandpaper**, even if it is difficult to see.
- **Palpation:** Running a finger over the area can help distinguish an actinic keratosis from smoother, unaffected skin.

b) Dermoscopy:

- **Dermoscopy:** A non-invasive tool used to evaluate the lesion. In AK, dermoscopy may reveal **erythematous background, scale,** and **hyperkeratosis**. It helps differentiate AK from **invasive SCC** and other skin lesions.

c) Skin Biopsy:

- **Biopsy** is not routinely required for typical AKs. However, if the lesion is:
 - **Thickened.**
 - **Tender.**
 - **Rapidly growing.**
 - **Ulcerated.**
 - Shows suspicion for invasive **SCC** or another malignancy.

In these cases, a **punch biopsy** or **shave biopsy** can be performed to rule out squamous cell carcinoma.

4. Explanation of Investigations:

- **Dermoscopy:** Provides a closer look at the lesion's structure, helping differentiate AK from other skin conditions like **SCC, basal cell carcinoma,** or **seborrheic keratosis**.
- **Biopsy:** If there is suspicion of progression to **SCC**, a biopsy is performed to assess for **cellular atypia, thickness,** and evidence of dermal invasion.

5. Diagnosis Criteria for Actinic Keratosis:

Actinic keratosis is diagnosed based on clinical findings, such as the presence of a **rough, scaly patch** on sun-exposed skin, with or without erythema or tenderness. The key histopathological features, if a biopsy is done, include:

- **Atypical keratinocytes:** Abnormal cells confined to the **epidermis**, without dermal invasion (indicating no SCC yet).
- **Hyperkeratosis:** Thickening of the stratum corneum (outermost layer of the skin) due to chronic sun exposure.
- **Parakeratosis:** Retention of nuclei in the stratum corneum, reflecting abnormal maturation of keratinocytes.

6. First-Line Therapy According to Guidelines:

Treatment for AK aims to **remove the lesion** and **prevent progression** to SCC. Several effective treatments are available, depending on the **extent** and **location** of the lesions.

a) Cryotherapy:

1. **Liquid nitrogen cryotherapy:**

- **First-line therapy** for isolated or localized AKs. Liquid nitrogen is applied to freeze and destroy the abnormal cells, causing the lesion to slough off.
- **Application:** A cryospray or cotton-tipped applicator is used to deliver **liquid nitrogen** for **5-15 seconds**. The lesion then blisters and peels off within a few weeks.
- **Side effects:** May include hypopigmentation (skin lightening) and scarring.

b) Topical Therapies:

1. 5-Fluorouracil (5-FU):

- A **topical chemotherapeutic agent** used for **multiple or diffuse AKs**. It works by inhibiting DNA synthesis in abnormal keratinocytes, causing them to die off.
- Applied once or twice daily for **2-4 weeks**.
- **Side effects:** Redness, peeling, and crusting at the treatment site are common but temporary.

2. Imiquimod:

- A **topical immunomodulator** that stimulates the immune system to destroy abnormal keratinocytes.
- Used for **superficial AKs**; applied 2-3 times per week for **4-6 weeks**.
- **Side effects:** Redness, irritation, and swelling at the application site.

3. Diclofenac gel:

- A **non-steroidal anti-inflammatory drug (NSAID)** applied topically to reduce inflammation and abnormal keratinocyte proliferation. Applied twice daily for **2-3 months**.
- **Side effects:** Mild irritation or peeling.

4. Ingenol mebutate gel:

- A plant-derived therapy that induces cell death in dysplastic keratinocytes. It is applied for **2-3 days** and is highly effective in clearing AKs.
- **Side effects:** Redness, blistering, and swelling.

c) Photodynamic Therapy (PDT):

- **PDT** involves applying a photosensitizing agent (e.g., **aminolevulinic acid**) to the affected area, followed by exposure to a specific wavelength of light to activate the agent and destroy the abnormal cells.
- **PDT** is especially useful for **multiple lesions** or in **cosmetically sensitive areas** like the face or scalp.
- **Side effects:** Local discomfort, redness, and photosensitivity post-treatment.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Cryotherapy:** May not be suitable for patients with **pigmented skin**, as it can cause hypopigmentation. It may also be avoided in sensitive areas like the eyelids.
- **Topical 5-FU or Imiquimod:** Not recommended for use in **pregnant women** or patients with **sensitive skin**.

b) Second-Line Therapy:

1. Curettage and Electrodesiccation:

- For **thickened AKs** or lesions not responding to cryotherapy, curettage (scraping off the lesion) followed by electrodesiccation (application of heat) can be used.

2. Laser therapy:

- **Ablative lasers** (e.g., **carbon dioxide laser**) can be used to vaporize the lesion in cases where other treatments are ineffective or inappropriate.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** Patients with a history of AK should have regular follow-up exams every **6-12 months** to monitor for new lesions or signs of progression to **SCC**.
- **Self-monitoring:** Patients should be instructed to regularly inspect their skin for new or changing lesions and report any suspicious changes to their healthcare provider.
- **Sun protection:** Patients should be educated about the importance of **sun protection**, including using **broad-spectrum sunscreen** (SPF 30 or higher), wearing **protective clothing**, and avoiding **tanning beds**.

9. Complications:

1. **Progression to Squamous Cell Carcinoma (SCC):**
 - AK is considered a **precancerous lesion**, and **0.1% to 10%** of AKs can progress to SCC if left untreated.
2. **Recurrence:**
 - Despite treatment, AKs may recur, especially if the patient continues to have significant sun exposure.
3. **Cosmetic changes:**
 - Treatment modalities, particularly cryotherapy, can result in **hypopigmentation** or **scarring**.

Summary of Key Points for Actinic Keratosis:

- **Actinic keratosis (AK)** is a **pre-cancerous lesion** caused by **chronic sun exposure** and serves as a marker for an increased risk of **skin cancer**, particularly **squamous cell carcinoma**.
- AK presents as **rough, scaly patches** or plaques on **sun-exposed areas**, and may be red, pink, or skin-coloured

87. Bowen's Disease

1. Detailed Definition of Bowen's Disease:

Bowen's disease is an early form of **squamous cell carcinoma in situ**, where **abnormal, dysplastic cells** are confined to the **epidermis** (the outermost layer of the skin). It is a **precancerous lesion** and, if left untreated, can progress to **invasive squamous cell carcinoma (SCC)**. Bowen's disease is also known as **intraepidermal carcinoma**.

2. Common Presenting Complaints and Symptoms:

- **Well-demarcated, scaly red patch:** The lesion is often described as a **slow-growing, persistent**, and **scaly** patch that may have **irregular borders**.
- **Itching or mild discomfort:** Bowen's disease is usually asymptomatic, but some patients may experience mild itching, tenderness, or irritation.
- **Crusting or erosion:** The surface may become **crusty** or develop **small erosions** but does not typically ulcerate unless it progresses to invasive SCC.
- **Non-healing lesion:** The patch does not heal with standard treatments like emollients or corticosteroids.

Common Sites Affected:

- **Sun-exposed areas:** The most common locations include the **face, ears, neck, hands, and legs**.

- **Mucosal surfaces:** Bowen's disease can also occur on mucosal surfaces such as the **genitalia** (referred to as **erythroplasia of Queyrat** when it affects the penis) or **perianal area**.

3. First-Line Investigations:

a) Clinical Examination:

- **Full skin examination:** Bowen's disease often presents as a **well-demarcated, erythematous, scaly plaque**. It is essential to examine all sun-exposed and non-exposed skin, particularly in older adults with chronic sun damage.

b) Dermoscopy:

- **Dermoscopy:** A non-invasive tool used to examine the lesion. In Bowen's disease, it may reveal **scaling, erythematous background, and vascular patterns**. It is helpful in distinguishing Bowen's disease from other lesions like psoriasis or superficial basal cell carcinoma.

c) Skin Biopsy:

- **Punch biopsy or shave biopsy:** This is the **gold standard** for diagnosing Bowen's disease. The biopsy will confirm the presence of **atypical keratinocytes** confined to the epidermis, without invasion into the dermis.

4. Explanation of Investigations:

- **Dermoscopy:** Helps differentiate Bowen's disease from other skin conditions such as **psoriasis, eczema, or superficial basal cell carcinoma**.
- **Skin biopsy:** Confirms the diagnosis by identifying **atypical squamous cells** that are confined to the **epidermis** without evidence of invasion into the dermis (which would indicate progression to invasive SCC).

5. Diagnosis Criteria for Bowen's Disease:

Bowen's disease is diagnosed based on clinical findings and confirmed by **histopathology**. The key histopathological features include:

- **Atypical keratinocytes:** Abnormal squamous cells that are confined to the epidermis.
- **Full-thickness epidermal dysplasia:** Atypical cells are present throughout the entire thickness of the epidermis but do not invade the dermis.
- **Hyperkeratosis:** Thickening of the outer layer of the skin.
- **Parakeratosis:** Retention of nuclei in the stratum corneum, indicating abnormal maturation of keratinocytes.

6. First-Line Therapy According to Guidelines:

Several effective treatments are available depending on the **size, location, and patient preferences**. The goal is to **remove or destroy the lesion** to prevent progression to invasive SCC.

a) Cryotherapy:

1. Liquid nitrogen cryotherapy:

- Commonly used for **small lesions**. The lesion is frozen with **liquid nitrogen**, causing the abnormal cells to slough off.
- **Application:** A cryospray or cotton-tipped applicator is used to apply liquid nitrogen to the lesion for **10-20 seconds**. Healing takes a few weeks.
- **Side effects:** Temporary **hypopigmentation** or **scarring**.

b) Topical Therapies:

1. 5-Fluorouracil (5-FU):

- A **topical chemotherapeutic agent** applied to the affected area. It inhibits DNA synthesis in dysplastic keratinocytes, causing them to die off.
 - Applied once or twice daily for **2-4 weeks**.
 - **Side effects:** Redness, scaling, and irritation at the application site.
2. **Imiquimod:**
- A **topical immunomodulator** that stimulates the immune system to attack the abnormal cells. Applied **2-5 times per week** for **4-6 weeks**.
 - **Side effects:** Redness, crusting, and irritation at the treatment site.

c) Curettage and Electrodessication:

- Suitable for **small, well-defined lesions**. The lesion is **scraped off** with a curette, and the base is treated with **electrodessication** (application of heat) to destroy any remaining abnormal cells.

d) Photodynamic Therapy (PDT):

- **PDT** is particularly useful for **large areas** or **cosmetically sensitive areas** like the face. A photosensitizing agent (e.g., **aminolevulinic acid**) is applied to the lesion, followed by exposure to a specific wavelength of light to destroy the dysplastic cells.
- **Side effects:** Local discomfort, redness, and photosensitivity after treatment.

e) Surgical Excision:

- **Surgical excision** with a margin of normal tissue may be necessary for **larger** or **thicker lesions** or those located in high-risk areas.
- **Mohs micrographic surgery** is an option for lesions in **cosmetically sensitive areas** (e.g., face, ears) or for **recurrent cases**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Cryotherapy:** May not be suitable for **larger lesions** or areas where scarring may be problematic (e.g., on the face).
- **Topical 5-FU or Imiquimod:** Should be avoided in **pregnant women** or patients with **severe irritation** from previous topical treatments.

b) Second-Line Therapy:

1. **Laser Therapy:**
 - **Ablative lasers** (e.g., **carbon dioxide laser**) can be used to vaporize the lesion in cases where other treatments are ineffective or inappropriate.
2. **Radiotherapy:**
 - May be considered for **large** or **unresectable lesions**, or in patients who are **poor surgical candidates**.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** Patients with a history of Bowen's disease require **follow-up visits every 6-12 months** to monitor for recurrence or the development of invasive SCC.
- **Self-monitoring:** Patients should be encouraged to regularly check their skin for any new lesions or changes in existing lesions and report any suspicious findings to their healthcare provider.
- **Sun protection:** Patients should be advised to practice **sun safety** by using **broad-spectrum sunscreen**, wearing **protective clothing**, and avoiding **tanning beds**.

9. Complications:

1. Progression to Squamous Cell Carcinoma (SCC):

- Bowen's disease has the potential to evolve into **invasive SCC**, particularly if left untreated or inadequately treated. The risk of progression is estimated to be **3-5%**.

2. Recurrence:

- Even after treatment, Bowen's disease can recur, especially in areas of chronic sun damage. The risk of recurrence depends on the treatment modality used.

3. Cosmetic changes:

- Treatments such as **cryotherapy** or **surgical excision** may lead to **scarring** or **hypopigmentation**, particularly in cosmetically sensitive areas.

Summary of Key Points for Bowen's Disease:

- **Bowen's disease** is an **early form of squamous cell carcinoma in situ**, characterized by **full-thickness dysplasia** of the epidermis.
- It presents as a **well-demarcated, scaly, erythematous patch**, often on **sun-exposed areas**.
- **Cryotherapy, topical therapies** (e.g., **5-FU, imiquimod**), **photodynamic therapy**, and **surgical excision** are the main treatment options.
- Regular **monitoring** is essential due to the risk of progression to **invasive squamous cell carcinoma** and potential recurrence.

88. Cutaneous Lymphoma

1. Detailed Definition of Cutaneous Lymphoma:

Cutaneous lymphoma refers to a group of **rare lymphoproliferative disorders** where **malignant lymphocytes** (white blood cells) localize primarily in the **skin**. These malignancies arise in **T cells** (cutaneous T-cell lymphoma or **CTCL**) or **B cells** (cutaneous B-cell lymphoma or **CBCL**), though T-cell variants are more common. Cutaneous lymphoma often presents as **skin lesions**, which may resemble eczema or psoriasis in the early stages. Although it primarily affects the skin, it can spread to the **lymph nodes** and **internal organs** in advanced stages.

2. Common Presenting Complaints and Symptoms:

Cutaneous T-Cell Lymphoma (CTCL):

Mycosis Fungoides is the most common subtype of CTCL.

- **Red, scaly patches:** Early lesions resemble patches of **eczema** or **psoriasis**, usually found on sun-protected areas like the **buttocks, hips, or thighs**.
- **Plaques:** Progression from patches to thicker, raised **plaques** that may become itchy or painful.
- **Tumours:** In advanced stages, raised **tumours** may form, which can ulcerate or become infected.
- **Itching (pruritus):** Significant itching is common, especially in more advanced stages.
- **Lymphadenopathy:** Enlarged lymph nodes may develop as the disease progresses.

Sezary Syndrome:

- **Erythroderma:** Widespread, diffuse **redness** and **scaling** of the skin affecting over 80% of the body.
- **Intense itching:** Patients often report severe pruritus.
- **Palmoplantar keratoderma:** Thickening of the skin on the palms and soles.

- **Enlarged lymph nodes:** Lymphadenopathy is common.
- **Circulating malignant T-cells:** Malignant T-cells can be found in the blood (Sezary cells), a hallmark of this variant.

Cutaneous B-Cell Lymphoma (CBCL):

- **Red or purple nodules:** Often solitary or clustered, painless nodules or plaques on the head, neck, or trunk.
- **Ulceration:** Lesions may break down, leading to open sores or ulcers in advanced disease.
- **Lymphadenopathy:** Swollen lymph nodes may occur.

3. First-Line Investigations:

a) Clinical Examination:

- **Full skin examination:** Assess for patches, plaques, or nodules that are characteristic of cutaneous lymphoma. Early lesions can mimic benign conditions like eczema or psoriasis, making a thorough assessment essential.

b) Skin Biopsy:

- **Gold standard for diagnosis:** A **punch biopsy** or **excisional biopsy** of the lesion is essential to confirm the diagnosis. The biopsy will show atypical lymphocytes infiltrating the skin.
 - In **CTCL**, the biopsy may reveal **atypical T-cells** with **epidermotropism** (infiltration into the epidermis).
 - In **CBCL**, the biopsy will show **atypical B-cells** localized in the dermis.

c) Blood Tests:

- **Complete blood count (CBC):** May show abnormal lymphocytes or an increased white blood cell count.
- **Peripheral blood smear:** In **Sezary syndrome**, a **blood smear** may reveal circulating **Sezary cells** (malignant T-cells).
- **Flow cytometry:** Can detect abnormal T-cell or B-cell populations in the blood.

d) Imaging:

- **CT scan or PET scan:** Used to assess the extent of the disease and check for lymph node involvement or spread to other organs.

4. Explanation of Investigations:

- **Skin biopsy:** The biopsy is critical for differentiating between CTCL, CBCL, and other inflammatory or neoplastic skin conditions. The presence of atypical lymphocytes and their localization in the epidermis or dermis helps confirm the diagnosis.
- **Flow cytometry:** Analyses cell surface markers to differentiate between malignant and non-malignant lymphocytes.
- **PET/CT scan:** Useful in staging the disease and assessing whether the lymphoma has spread beyond the skin to lymph nodes or internal organs.

5. Diagnosis Criteria for Cutaneous Lymphoma:

Cutaneous lymphoma is diagnosed based on **histopathology** from the skin biopsy, **immunophenotyping**, and sometimes **molecular studies**.

Histopathological features:

- **CTCL:** Presence of **atypical T-cells** with characteristic **cerebriform nuclei**. Epidermotropism is often seen.
- **CBCL:** Infiltration of **atypical B-cells** in the dermis or subcutaneous tissue.

Immunophenotyping:

- **CTCL:** T-cell lymphomas are typically **CD3-positive** and **CD4-positive**.
- **CBCL:** B-cell lymphomas are **CD20-positive**.

Molecular studies:

- **T-cell receptor (TCR) gene rearrangement** testing for CTCL.
- **Immunoglobulin gene rearrangement** for CBCL.

6. First-Line Therapy According to Guidelines:

The treatment of cutaneous lymphoma depends on the **stage** of the disease, the **subtype**, and whether the disease is **localized** or **widespread**.

a) Early-Stage (Localized):

1. **Topical corticosteroids:**
 - Often used as **first-line treatment** for **early-stage mycosis fungoides** to reduce inflammation and control symptoms.
2. **Phototherapy:**
 - **Psoralen plus ultraviolet A (PUVA)** or **narrowband UVB therapy** is effective for **patches and plaques** of CTCL. It works by targeting abnormal T-cells in the skin.
3. **Topical chemotherapy:**
 - **Mechlorethamine (nitrogen mustard):** Applied topically to treat localized CTCL lesions.
 - **Carmustine:** Another topical chemotherapeutic option for localized CTCL.
4. **Radiotherapy:**
 - **Localized radiotherapy** can be used to treat **single or small clusters** of cutaneous lesions in both CTCL and CBCL.

b) Advanced-Stage (Widespread or Systemic):

1. **Systemic Therapy:**
 - **Oral retinoids** (e.g., **bexarotene**): Used in **advanced CTCL** to inhibit the growth of malignant T-cells.
 - **Interferon-alpha:** An immune-modulating agent that can slow disease progression in advanced CTCL.
 - **Chemotherapy:** For **more advanced disease** or **systemic involvement**, combination chemotherapy regimens (e.g., **CHOP**: cyclophosphamide, doxorubicin, vincristine, and prednisone) may be used.
 - **Extracorporeal photopheresis (ECP):** Used in **Sezary syndrome**, it involves removing blood, treating it with light, and then returning it to the patient to target malignant T-cells.
2. **Targeted Therapy:**
 - **Monoclonal antibodies:**
 - **Brentuximab vedotin:** Targeted therapy for **CD30-positive CTCL**.
 - **Rituximab:** Used in **cutaneous B-cell lymphoma** to target CD20-positive malignant cells.
3. **Stem Cell Transplant:**
 - In rare, aggressive cases, **allogeneic stem cell transplantation** may be considered for **younger patients** or those with refractory disease.

7. Contraindications and Second-Line Therapy:

a) Contraindications:

- **Topical corticosteroids:** Long-term use can lead to **skin thinning**, so they are not suitable for **extensive or chronic use** on large body areas.
- **Radiotherapy:** Not suitable for patients with **widespread disease**, as it is typically localized.

b) Second-Line Therapy:

1. **Systemic retinoids:**
 - **Bexarotene** may be used if initial topical treatments fail, especially in advanced disease.
2. **Oral methotrexate:**
 - An option for patients who do not respond to topical treatments or phototherapy.
3. **Histone deacetylase (HDAC) inhibitors:**
 - **Vorinostat** or **romidepsin** can be used in refractory CTCL.

8. Routine Monitoring and Follow-Up:

- **Regular skin examinations:** Patients should undergo regular dermatologic evaluations every **3-6 months**, depending on the stage and response to treatment.
- **Blood tests:** In patients with **Sezary syndrome** or advanced CTCL, regular blood tests to monitor **circulating Sezary cells** are necessary.
- **Imaging:** CT or PET scans may be used periodically to assess for lymph node or visceral involvement in advanced disease.
- **Patient education:** Patients should be educated on the importance of **self-monitoring** for new or changing lesions and reporting any signs of systemic involvement.

9. Complications:

1. **Progression to systemic disease:**
 - In advanced stages, cutaneous lymphoma can spread beyond the skin to **lymph nodes** and **internal organs**, including the **liver, spleen, and lungs**. This can significantly worsen the prognosis.
2. **Secondary infections:**
 - Due to compromised skin integrity from chronic lesions and immunosuppressive treatments, patients are at increased risk of **bacterial, viral, and fungal infections**.
3. **Itching and skin discomfort:**
 - Persistent pruritus (itching) can cause significant discomfort, affect quality of life, and lead to **sleep disturbances** and **emotional stress**.
4. **Complications from treatments:**
 - Long-term use of **topical steroids** can lead to **skin thinning, telangiectasia, and striae**.
 - **Systemic treatments**, including chemotherapy, can cause **immunosuppression**, increasing the risk of **infections** and **treatment-related toxicities** (e.g., liver and kidney dysfunction).

Summary of Key Points for Cutaneous Lymphoma:

- **Cutaneous lymphoma** refers to a group of lymphoproliferative disorders that primarily affect the skin, with **cutaneous T-cell lymphoma (CTCL)** being the most common subtype.
- Early lesions may mimic **eczema** or **psoriasis**, but biopsy reveals **atypical lymphocytes** confined to the epidermis.

- **Skin biopsy** is the gold standard for diagnosis, while **imaging** and **blood tests** are important for staging and monitoring progression.
- **First-line treatments** include **topical corticosteroids**, **phototherapy**, and **topical chemotherapy** for localized disease, with **systemic therapy** (e.g., retinoids, interferon, or chemotherapy) for more advanced cases.
- Regular **monitoring** for recurrence or progression to systemic disease is essential, as is **patient education** on self-monitoring and sun protection.

89. Melanocytic Naevi (Moles)

1. Detailed Definition of Melanocytic Naevi:

Melanocytic naevi (commonly known as **moles**) are benign proliferations of **melanocytes**, the pigment-producing cells in the skin. These naevi are often seen as small, pigmented spots on the skin and can vary in size, shape, and colour. While most melanocytic naevi are benign and pose no health risks, certain types, particularly **atypical naevi**, can increase the risk of developing **melanoma**, a dangerous form of skin cancer.

2. Common Presenting Complaints and Symptoms:

- **Flat or raised pigmented lesions:** Moles can appear as either flat or raised, and their colour can range from **brown**, **black**, **pink**, or **flesh-coloured**.
- **Symmetry:** Benign naevi are typically **symmetrical** with **regular borders**.
- **Uniform colour:** Most benign naevi are evenly coloured, but the colour can vary between individuals based on their skin tone.
- **Size:** Benign naevi are usually less than **6 mm** in diameter, though larger moles may also be benign.
- **Itching or discomfort:** Rarely, patients may complain of itching or irritation, but benign naevi are usually asymptomatic.

Common Sites Affected:

- **Sun-exposed areas:** Melanocytic naevi are more common in areas exposed to the sun, such as the **face**, **arms**, and **trunk**, but they can appear anywhere on the body.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** The most important step in evaluating a melanocytic naevus. Look for changes in the **size**, **shape**, **colour**, and **symmetry** of the mole.
- **ABCDE rule:** To differentiate benign moles from suspicious lesions, clinicians use the **ABCDE criteria**:
 - **A: Asymmetry** – benign naevi are typically symmetrical.
 - **B: Border** – benign naevi have regular, smooth borders.
 - **C: Colour** – benign naevi usually have uniform colour.
 - **D: Diameter** – benign naevi are generally smaller than **6 mm** in diameter.
 - **E: Evolution** – changes over time, particularly growth or colour changes, may indicate malignancy.

b) Dermoscopy:

- **Dermoscopy:** A non-invasive technique that allows for a magnified view of the skin's surface. It helps identify patterns in pigmented lesions that may not be visible to the naked eye. Dermoscopy can be useful in distinguishing **benign naevi** from **melanoma** or **atypical naevi**.

c) Biopsy:

- **Excisional biopsy:** If there is suspicion that a naevus may be malignant or atypical (e.g., based on dermoscopy or clinical findings), an **excisional biopsy** can be performed to remove the mole and assess it histologically for **dysplasia** or **malignancy**.

4. Explanation of Investigations:

- **Dermoscopy:** Identifies features like **pigment networks**, **streaks**, and **dots** that help differentiate between benign moles and more suspicious lesions like melanoma.
- **Biopsy:** Provides a histopathological examination of the mole, which is essential for confirming whether the lesion is benign, atypical, or malignant.

5. Diagnosis Criteria for Melanocytic Naevi:

Melanocytic naevi are diagnosed based on clinical findings. The key histological features seen in biopsy (if performed) include:

- **Proliferation of melanocytes:** Melanocytes are found in **clusters (nests)** at the **dermoepidermal junction** in **junctional naevi** or in the **dermis** in **dermal naevi**.
- **Symmetry:** Benign naevi typically show **symmetry** and **regular architecture**.
- **Uniform pigmentation:** The pigment is evenly distributed throughout the lesion.

Types of melanocytic naevi include:

1. **Junctional naevi:** Melanocytes are located at the junction between the epidermis and dermis. These moles are typically flat and pigmented.
2. **Compound naevi:** Melanocytes are located both at the junction and within the dermis. These moles are often raised and pigmented.
3. **Intradermal naevi:** Melanocytes are located exclusively within the dermis. These moles are usually raised and can be flesh-coloured or lightly pigmented.

6. First-Line Therapy According to Guidelines:

Most benign melanocytic naevi do not require treatment unless they are:

- **Symptomatic** (e.g., painful or itching).
- **Cosmetically bothersome** to the patient.
- **Suspicious** for malignancy based on clinical features.

a) Surgical Excision:

1. **Excisional biopsy:**
 - If there are concerns about a naevus being **atypical** or potentially malignant, a **complete excision** is recommended with a small margin of normal skin. The excised tissue is then sent for **histological examination**.
 - This ensures that the entire lesion is removed and allows for histopathologic confirmation of the diagnosis.

b) Observation:

- **Benign naevi** that do not show signs of dysplasia or malignancy can be **monitored** over time. Patients should be educated to look for changes in size, shape, colour, or symptoms and report any concerns to their physician.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Surgical Excision:

- **Extensive naevi** or those in **cosmetically sensitive areas** (e.g., the face) may not be suitable for surgical removal unless malignancy is suspected.

b) Second-Line Therapy:

1. **Shave excision:**

- For benign or non-suspicious moles that are raised and bothersome, a **shave excision** can be performed. This procedure is quicker than a full excision but does not remove the entire depth of the lesion.
- 2. **Laser therapy:**
 - May be used for the removal of **benign melanocytic naevi** for cosmetic purposes. However, this is not typically recommended for naevi with suspicious features, as laser therapy does not allow for histopathological examination.

8. Routine Monitoring and Follow-Up:

- **Regular skin checks:** Individuals with many moles or a family history of melanoma should have routine dermatologic evaluations to monitor their naevi.
- **Self-examination:** Patients should be educated to perform **monthly self-examinations** using the **ABCDE criteria** to assess their moles for any changes. New or changing lesions should be reported to a healthcare provider immediately.
- **Sun protection:** Educate patients on the importance of sun protection (using **broad-spectrum sunscreen**, wearing protective clothing) to reduce the risk of developing new naevi and the potential transformation of existing naevi.

9. Complications:

1. **Malignant transformation:**
 - Though most melanocytic naevi are benign, certain subtypes, such as **atypical or dysplastic naevi**, have the potential to transform into **melanoma**.
2. **Cosmetic concerns:**
 - Large or numerous naevi, particularly on the face or other visible areas, can be cosmetically distressing for some patients.
3. **Scarring:**
 - Surgical removal, particularly of larger or deeper naevi, may result in **scarring**, especially in cosmetically sensitive areas.

Summary of Key Points for Melanocytic Naevi:

- **Melanocytic naevi** are benign proliferations of **melanocytes** and are common in both children and adults. They can appear anywhere on the body but are more prevalent in **sun-exposed areas**.
- Most naevi are **asymptomatic** and require no treatment unless they are **cosmetically concerning** or display features suspicious for **melanoma**.
- **ABCDE criteria** are used to evaluate melanocytic naevi for signs of malignancy, with **biopsy** or **excision** recommended if suspicious features are present.
- **Sun protection** and **routine monitoring** are essential to prevent new lesions and monitor for changes in existing naevi.

90. Seborrhoeic Keratoses

1. Detailed Definition of Seborrhoeic Keratoses:

Seborrhoeic keratoses (SK) are **benign epidermal tumours** that originate from **keratinocytes**. They are also known as **basal cell papillomas**, **senile warts**, or **seborrhoeic warts**. SKs are **non-cancerous growths** that are extremely common, especially in older adults, and can vary widely in size, shape, and colour. Although seborrhoeic keratoses can be unsightly, they do not typically pose any health risks.

2. Common Presenting Complaints and Symptoms:

- **Warty, "stuck-on" appearance:** Seborrhoeic keratoses typically appear as **warty, raised lesions** that look as though they are "stuck on" the surface of the skin.
- **Varied colour:** The colour can range from **pale yellow** to **dark brown** or **black**.
- **Surface texture:** The surface is often **rough** and may be **scaly**, though some lesions can be smooth or waxy.
- **Size:** Seborrhoeic keratoses vary in size from a few millimeters to several centimeters.
- **Asymptomatic:** SKs are usually **painless** and **non-itchy**, though some may become irritated, particularly if they are in areas prone to **rubbing** or **friction**.
- **Multiple lesions:** It is common to have **multiple SKs**, which can appear gradually over time.

Common Sites Affected:

- **Trunk:** The back, chest, and abdomen are the most common sites.
- **Face, neck, and scalp:** These areas are also frequently affected.
- **Limbs:** Occasionally seen on the arms and legs but are less common.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Seborrhoeic keratoses are usually diagnosed based on their **characteristic appearance**. The lesions are often described as **waxy, well-demarcated**, and having a **stuck-on appearance**.
- **Palpation:** The texture of the lesion often feels rough or greasy when touched.

b) Dermoscopy:

- **Dermoscopy:** A non-invasive tool used to enhance the visualization of skin lesions. Dermoscopic features of seborrhoeic keratoses include:
 - **Milia-like cysts:** Small white or yellow cystic structures.
 - **Comedo-like openings:** Resembling blackheads.
 - **Network-like or fingerprint-like patterns.**
 - **Sharp borders** and lack of vascular patterns typical of malignancies.

c) Biopsy:

- **Skin biopsy:** Not routinely required but may be performed if there is doubt about the diagnosis, especially if a seborrhoeic keratosis is unusually pigmented, inflamed, or shows atypical features. The biopsy will confirm benign **proliferation of keratinocytes** without evidence of malignancy.

4. Explanation of Investigations:

- **Dermoscopy:** Helps differentiate seborrhoeic keratoses from other pigmented lesions such as **melanoma, basal cell carcinoma, or pigmented actinic keratosis**.
- **Biopsy:** Provides histological confirmation if the lesion has atypical features, such as rapid growth, irregular pigmentation, or ulceration, to rule out **malignancy**.

5. Diagnosis Criteria for Seborrhoeic Keratoses:

Seborrhoeic keratoses are typically diagnosed clinically based on their **characteristic appearance** and **dermoscopic findings**. Key histopathological features (if a biopsy is performed) include:

- **Hyperkeratosis:** Thickened stratum corneum (outermost skin layer).
- **Acanthosis:** Thickening of the epidermis with proliferating keratinocytes.
- **Horn cysts:** Cysts filled with keratin, often seen in seborrhoeic keratoses.

- **Basaloid cells:** Proliferation of basaloid cells without any evidence of atypia or malignancy.

6. First-Line Therapy According to Guidelines:

Most seborrhoeic keratoses are **benign** and **do not require treatment** unless they are symptomatic, irritated, or cosmetically concerning to the patient. Treatment is elective and aimed at removing the lesion for **cosmetic purposes** or if it becomes symptomatic (e.g., due to irritation or bleeding).

a) Cryotherapy:

1. Liquid nitrogen cryotherapy:

- The most common treatment option for seborrhoeic keratoses. The lesion is **frozen** with liquid nitrogen, causing it to slough off over the course of several weeks.
- **Application:** A cryospray or cotton-tipped applicator is used to deliver **liquid nitrogen** to the lesion for **10-20 seconds**.
- **Side effects:** Hypopigmentation and scarring, particularly in darker skin types.

b) Curettage and Electrodessication:

- **Curettage** involves scraping the lesion off with a curette. This is often combined with **electrodessication** (heat application) to destroy any remaining keratinocytes.
- Particularly useful for **larger or thicker lesions**.

c) Shave Excision:

- A **shave excision** is used to remove seborrhoeic keratoses that are raised. This is a simple procedure that involves shaving the lesion off at the base.
- **Side effects:** Minimal scarring, depending on the size and depth of the lesion.

d) Laser Therapy:

- **Ablative lasers** (e.g., CO2 laser) can be used to vaporize the lesion, especially for cosmetically sensitive areas.
- **Side effects:** Redness, swelling, and temporary discoloration.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Cryotherapy:** May not be suitable for patients with **darker skin types** due to the risk of **hypopigmentation**.
- **Shave excision:** Not ideal for **flat lesions** or seborrhoeic keratoses located in areas where scarring would be problematic.

b) Second-Line Therapy:

1. Topical Treatment:

- **Topical agents** like **hydrogen peroxide solution (Eskata)** can be applied to seborrhoeic keratoses to cause gradual fading of the lesion. However, this is not commonly used and may not be as effective as physical removal.

2. Chemical Peels:

- **Trichloroacetic acid (TCA) peels** can be used to treat **multiple** small seborrhoeic keratoses.

8. Routine Monitoring and Follow-Up:

- **No follow-up** is usually required after treatment unless complications arise or the patient notices changes in the lesion that could indicate a misdiagnosis or malignancy.

- Patients with multiple seborrhoeic keratoses should be educated to monitor for any **sudden changes** in size, shape, or colour of their lesions.
- **Sun protection:** Encourage patients to use **broad-spectrum sunscreen** and avoid excessive sun exposure, as seborrhoeic keratoses often occur in sun-exposed areas.

9. Complications:

1. **Cosmetic concerns:**
 - Seborrhoeic keratoses can be cosmetically distressing, especially if they appear on the face or other visible areas.
2. **Irritation or bleeding:**
 - Lesions that are located in areas prone to **friction** (e.g., under the bra line, waist, or armpits) may become irritated, leading to **bleeding, itching, or pain**.
3. **Post-treatment pigmentation changes:**
 - **Cryotherapy** and **laser treatments** can result in **hypopigmentation** or **hyperpigmentation**, particularly in patients with darker skin types.
- 4.

Summary of Key Points for Seborrhoeic Keratoses:

- **Seborrhoeic keratoses (SK)** are **benign, non-cancerous growths** that are common in older adults and are characterized by a **warty, "stuck-on" appearance**.
- SKs are usually asymptomatic, but they can become irritated or inflamed, especially in areas subject to friction.
- **Cryotherapy, shave excision, and curettage** are the most common treatments, but removal is not typically necessary unless the lesion is symptomatic or bothersome to the patient.
- Seborrhoeic keratoses are benign and do not transform into cancer, but they can occasionally mimic malignant lesions such as **melanoma**, so proper evaluation and monitoring are important.

91. Impetigo

1. Detailed Definition of Impetigo:

Impetigo is a highly contagious **superficial bacterial skin infection**, most commonly caused by **Staphylococcus aureus** or **Streptococcus pyogenes**. It typically affects children but can occur in people of all ages. Impetigo presents as **vesicles** or **pustules** that rupture to form **honey-coloured crusts**. There are two main forms:

- **Non-bullous impetigo:** The more common form, characterized by small vesicles and pustules that rupture, leaving behind crusted lesions.
- **Bullous impetigo:** Caused by **Staphylococcus aureus**, leading to larger fluid-filled blisters.

2. Common Presenting Complaints and Symptoms:

- **Honey-coloured crusting:** This is the classic feature of impetigo, where vesicles or pustules rupture and leave a yellow-brown crust.
- **Red macules or papules:** Early lesions may appear as small, red macules or papules before progressing to pustules or vesicles.
- **Pruritus (itching):** Lesions are often itchy, which can lead to scratching and further spread of the infection.
- **Erosions:** When vesicles or bullae rupture, they leave behind **shallow erosions** that eventually crust over.

- **Bullous impetigo:** In this form, patients present with larger, flaccid blisters filled with yellow fluid, which rupture easily and may leave behind a thin brown crust.
- **Systemic symptoms (bullous impetigo):** While rare, patients with extensive bullous impetigo may experience **fever, malaise, or lymphadenopathy**.

Common Sites Affected:

- **Face:** Impetigo commonly affects the **perioral** and **perinasal areas**.
- **Extremities:** Arms, legs, and areas of skin trauma are common sites.
- **Diaper area:** In infants, the diaper area is frequently affected by impetigo.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is primarily clinical, based on the characteristic appearance of **honey-coloured crusts** over erosions or ruptured vesicles.
- **Location:** Pay attention to commonly affected areas, such as the face and extremities.

b) Swab for bacterial culture:

- **Bacterial swab:** If the diagnosis is uncertain or if the impetigo is **severe** or **recurrent**, a swab for **bacterial culture** and **sensitivity testing** can help confirm the causative organism and guide antibiotic choice.
- **PCR testing:** In some cases, PCR can help confirm the presence of **Staphylococcus aureus** or **Streptococcus pyogenes**.

4. Explanation of Investigations:

- **Bacterial culture:** Identifies the **causative bacteria** (usually **Staphylococcus aureus** or **Streptococcus pyogenes**) and determines **antibiotic sensitivities**, especially if there is concern for **antibiotic resistance**.
- **PCR testing:** Helps identify the bacteria's genetic material, particularly useful in resistant or hard-to-diagnose cases.

5. Diagnosis Criteria for Impetigo:

Impetigo is diagnosed based on **clinical appearance**. Key features for diagnosis include:

- **Honey-coloured crusts** on an erythematous base, typically following vesicles or pustules.
- In **bullous impetigo**, the presence of **flaccid blisters** that rupture easily, leaving behind erosions and thin brown crusts.
- **No systemic symptoms** in non-bullous impetigo, while **fever or malaise** may accompany more severe cases of bullous impetigo.

6. First-Line Therapy According to Guidelines:

Treatment depends on the **severity** and **extent** of the infection, with localized cases typically requiring **topical therapy**, while widespread or severe cases may require **systemic antibiotics**.

a) Topical Therapy:

1. Topical Fusidic Acid:

- **First-line topical antibiotic** for localized impetigo.
- Applied **2-3 times daily** for **5-7 days**.
- **Mechanism:** Inhibits bacterial protein synthesis by preventing the turnover of elongation factor G, halting bacterial growth.

2. Topical Mupirocin:

- An alternative to fusidic acid if **resistant bacteria** are suspected or if fusidic acid fails.
- Applied **2-3 times daily** for **5-7 days**.
- **Mechanism:** Inhibits bacterial protein synthesis by targeting bacterial isoleucyl-tRNA synthetase.

b) Oral Antibiotics (if systemic or widespread):

1. Oral Flucloxacillin:

- First-line oral therapy for extensive impetigo or when topical treatment is insufficient.
- Adult dose: **500 mg four times daily** for **7 days**.
- Child dose: Weight-based dosing for 7 days.
- **Mechanism:** A penicillinase-resistant beta-lactam antibiotic that inhibits bacterial cell wall synthesis.

2. Oral Clarithromycin:

- Used if the patient is **penicillin-allergic** or if **MRSA** is suspected.
- Adult dose: **250-500 mg twice daily** for **7 days**.
- **Mechanism:** Macrolide antibiotic that inhibits bacterial protein synthesis.

c) General Measures:

- **Hygiene:** Good hygiene practices, such as **regular handwashing** and keeping nails short, can prevent the spread of impetigo.
- **Avoid scratching:** To reduce the risk of spreading infection to other parts of the body or to others.
- **Isolation:** Children with impetigo should be kept out of school or daycare for at least **24 hours after starting antibiotics** to prevent spreading the infection.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Topical therapy:** Not suitable for **extensive** or **bullous impetigo** or when the infection is **systemic** or **spreading rapidly**.
- **Flucloxacillin:** Contraindicated in patients with a **penicillin allergy**.

b) Second-Line Therapy:

1. Oral Cephalexin:

- Alternative antibiotic if the patient is **penicillin-allergic** and cannot tolerate **macrolides**.
- Adult dose: **500 mg four times daily** for **7 days**.
- **Mechanism:** Cephalosporin antibiotic that inhibits bacterial cell wall synthesis.

2. Oral Erythromycin:

- Another option for penicillin-allergic patients.
- **Mechanism:** Macrolide antibiotic that inhibits bacterial protein synthesis.

8. Routine Monitoring and Follow-Up:

- **Follow-up after treatment:** Most cases of impetigo resolve with treatment. Patients should be followed up if the infection **does not improve** after 7 days of treatment or if new symptoms develop.
- **Monitoring for complications:** Patients should be educated to monitor for signs of complications such as **cellulitis** (spreading skin infection) or **post-streptococcal glomerulonephritis** (rare complication of streptococcal infections).

9. Complications:

1. Cellulitis:

- Bacteria can invade deeper layers of the skin, leading to **cellulitis**, which presents with pain, redness, and swelling of the affected area.

2. Post-streptococcal glomerulonephritis:

- Rare but potentially serious complication of streptococcal impetigo. It involves inflammation of the kidneys, leading to **haematuria**, **oedema**, and **hypertension**.

3. Scar formation:

- Though rare, some impetigo lesions may leave scars, especially if they are scratched or become secondarily infected.

4. MRSA infection:

- Methicillin-resistant **Staphylococcus aureus (MRSA)** can cause impetigo, requiring specific antibiotic therapy (e.g., **mupirocin**, **doxycycline**, or **clindamycin**).

Summary of Key Points for Impetigo:

- **Impetigo** is a common and highly contagious **superficial bacterial skin infection**, usually caused by **Staphylococcus aureus** or **Streptococcus pyogenes**.
- It presents with **honey-coloured crusts** over erosions or ruptured vesicles, often affecting the **face** and **extremities**.
- **Topical antibiotics** (e.g., fusidic acid or mupirocin) are effective for localized cases, while **oral antibiotics** (e.g., flucloxacillin or clarithromycin) are used for more widespread or systemic infection.
- Good **hygiene practices** and **isolation** are important in preventing the spread of impetigo, especially in children.
- **Complications** such as **cellulitis** and **post-streptococcal glomerulonephritis** are rare but should be monitored for in severe

92. Erysipelas

1. Detailed Definition of Erysipelas:

Erysipelas is a type of superficial **bacterial skin infection** involving the **upper dermis** and extending into the superficial cutaneous lymphatics. It is most commonly caused by **group A Streptococcus (Streptococcus pyogenes)**, although other streptococcal species may also be involved. Erysipelas is characterized by its **sharp, raised borders**, **bright red coloration**, and **acute onset of symptoms**. It typically affects the face or lower limbs and presents with systemic signs of infection, such as fever.

2. Common Presenting Complaints and Symptoms:

- **Bright red, swollen, and warm skin:** The affected area appears **well-demarcated**, with a **shiny** and **tense** appearance.
- **Raised, sharp edges:** Unlike cellulitis, erysipelas typically has **clearly defined, raised borders**, which help distinguish it from other skin infections.
- **Pain and tenderness:** The skin feels tender and painful to the touch.
- **Fever and malaise:** Patients often present with **fever**, **chills**, and general **malaise**. Systemic symptoms may precede the skin changes.
- **Lymphadenopathy:** Swollen lymph nodes near the affected area (regional lymphadenopathy) are common.

- **Blisters or bullae:** In more severe cases, blisters or bullae may form on the erythematous area, especially in elderly patients or those with immune deficiencies.

Common Sites Affected:

- **Face:** Classically affects the **cheeks** and **nose**, leading to a "butterfly" distribution on the face.
- **Lower limbs:** The **legs** are commonly affected, particularly in patients with venous insufficiency, lymphedema, or after skin trauma.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Erysipelas can be diagnosed based on the clinical appearance of the skin, characterized by **well-demarcated erythema**, **swelling**, **warmth**, and **pain**. The skin typically has a **raised, shiny appearance** with clear borders.
- **Palpation:** The area is warm and may feel tense or firm to the touch due to the inflammation of the skin and underlying tissues.

b) Blood Tests:

- **Full blood count (FBC):** May show an **elevated white blood cell count** (leukocytosis), which indicates infection or inflammation.
- **C-reactive protein (CRP):** Elevated levels are indicative of inflammation and infection.
- **Erythrocyte sedimentation rate (ESR):** Often elevated, reflecting systemic inflammation.

c) Bacterial Swab and Blood Cultures:

- **Swab for culture:** A swab of any open blisters or bullae can be taken for **bacterial culture**, especially in severe or recurrent cases.
- **Blood cultures:** Performed if the patient presents with signs of **sepsis** (e.g., high fever, chills, rigors) to identify the causative organism and assess for bacteraemia.

d) Imaging:

- **Ultrasound or MRI:** If deeper involvement is suspected or to rule out **deep vein thrombosis (DVT)** or **necrotizing fasciitis**, imaging studies such as **ultrasound** or **MRI** can be considered.

4. Explanation of Investigations:

- **Full blood count (FBC):** Provides information about the body's response to infection, showing an elevated white blood cell count in most cases.
- **CRP and ESR:** These inflammatory markers help gauge the **severity of the infection**.
- **Swab and blood cultures:** Help confirm the bacterial cause, especially in patients who do not respond to initial treatment or present with systemic symptoms.
- **Imaging:** Ultrasound or MRI can help differentiate erysipelas from more serious conditions like **necrotizing fasciitis**.

5. Diagnosis Criteria for Erysipelas:

Erysipelas is typically diagnosed based on **clinical appearance**. Key features for diagnosis include:

- **Well-demarcated erythema** with raised borders.
- **Swelling, warmth**, and **pain** in the affected area.
- **Systemic symptoms** such as **fever**, **malaise**, and **lymphadenopathy**.
- **Rapid onset** and progression, with the affected skin area expanding over hours to days.

In cases of diagnostic uncertainty, a **bacterial swab** or **blood culture** may help confirm the **causative organism**.

6. First-Line Therapy According to Guidelines:

The management of erysipelas is aimed at eradicating the infection with **appropriate antibiotics** and reducing **inflammation**. The choice of treatment depends on the **extent of the infection**, the presence of **comorbidities**, and whether the patient presents with **systemic symptoms**.

a) Oral Antibiotics (Mild to Moderate Cases):

1. Penicillin V:

- First-line therapy for erysipelas caused by **Streptococcus pyogenes**.
- Adult dose: **500 mg four times daily** for **7-14 days**.
- **Mechanism:** Inhibits bacterial cell wall synthesis by targeting the penicillin-binding proteins, leading to cell death.

2. Amoxicillin:

- Another first-line option for streptococcal infections.
- Adult dose: **500 mg three times daily** for **7-14 days**.

3. Flucloxacillin:

- Used when **Staphylococcus aureus** infection is suspected (e.g., in cases with bullae or abscesses).
- Adult dose: **500 mg four times daily** for **7-14 days**.

b) Antibiotics for Penicillin-Allergic Patients:

1. Clarithromycin:

- For penicillin-allergic patients or those where **MRSA** is a concern.
- Adult dose: **250-500 mg twice daily** for **7-14 days**.

2. Clindamycin:

- Adult dose: **300-450 mg four times daily** for **7-14 days**.
- **Mechanism:** Inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit.

c) Intravenous Antibiotics (Severe Cases):

• Benzylpenicillin:

- IV therapy for severe or systemic cases of erysipelas.
- Adult dose: **1.2 g every 6 hours** for **7-14 days**.

• Ceftriaxone or Cefazolin:

Alternatives for patients with penicillin allergies or in severe cases.

d) Supportive Measures:

- **Elevation:** Elevating the affected limb (if erysipelas involves the legs) to reduce swelling and oedema.
- **Analgesia:** NSAIDs or paracetamol to control pain and fever.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Penicillin:** Should not be used in patients with a history of **penicillin allergy**.
- **Flucloxacillin:** Avoid in penicillin-allergic patients.

b) Second-Line Therapy:

1. Cefuroxime:

- An alternative to penicillin in patients with mild penicillin allergies.
- Adult dose: **250-500 mg twice daily** for **7-14 days**.

2. Linezolid:

- Used in severe cases of **MRSA** infection or penicillin-resistant organisms.

8. Routine Monitoring and Follow-Up:

- **Clinical response:** Symptoms should begin to improve within **48-72 hours** of starting antibiotics. Follow-up is important to ensure complete resolution of the infection.
- **Complications:** Monitor for complications such as **abscess formation**, **deep vein thrombosis (DVT)**, or **cellulitis** spreading deeper into the tissues.
- **Hospitalization:** Patients with **severe disease**, **systemic involvement**, or underlying **immunosuppression** may require hospital admission for IV antibiotics and monitoring.

9. Complications:

1. Recurrent Erysipelas:

- Recurrence is common, especially in patients with **chronic lymphedema** or **venous insufficiency**.
- Prophylactic penicillin may be considered in patients with frequent recurrences.

2. Cellulitis:

- Erysipelas can progress to deeper **cellulitis**, a more severe infection that affects the deeper dermis and subcutaneous fat.

3. Abscess formation:

- Secondary **abscesses** may develop in areas of untreated or inadequately treated erysipelas.

4. Sepsis:

- In severe cases, especially if left untreated, erysipelas can lead to **bacteraemia** and **septicaemia**, which requires urgent treatment.

Summary of Key Points for Erysipelas:

- **Erysipelas** is an **acute bacterial skin infection** characterized by **well-demarcated, raised borders** and **erythema**, often involving the **face** or **lower limbs**.
- It is commonly caused by **Streptococcus pyogenes** and presents with **fever**, **pain**, and **swelling** in the affected area.
- **First-line treatment** involves **oral penicillin** or **amoxicillin** for mild to moderate cases, and **IV antibiotics** (e.g., benzylpenicillin) for more severe or systemic cases.
- In **penicillin-allergic patients**, **clarithromycin** or **clindamycin** are effective alternatives.
- **Supportive measures** like **elevation of the limb** and **pain management** are essential for recovery.
- **Complications** include **cellulitis**, **abscess formation**, **recurrent infections**, and potentially **sepsis** in severe cases.
- Regular follow-up is essential to monitor the response to therapy and prevent complications.

93. Cellulitis

1. Detailed Definition of Cellulitis:

Cellulitis is a **bacterial skin infection** affecting the **deeper layers of the skin**, specifically the **dermis** and **subcutaneous tissue**. It commonly results from the entry of bacteria, often **Streptococcus pyogenes** or **Staphylococcus aureus**, through breaks in the skin. It is characterized by **erythema**, **swelling**, **heat**, and **pain** in the affected area. Unlike erysipelas,

which involves more superficial skin layers and has well-demarcated borders, cellulitis has **ill-defined borders** and may spread rapidly if left untreated.

2. Common Presenting Complaints and Symptoms:

- **Diffuse redness (erythema):** The skin appears red and inflamed, with poorly defined borders.
- **Swelling and oedema:** The affected area is swollen due to inflammation and fluid accumulation.
- **Warmth:** The skin feels warm to the touch as a result of the infection.
- **Pain and tenderness:** The infected area is often painful and tender, worsening with touch or movement.
- **Fever and malaise:** Systemic symptoms, such as **fever**, **chills**, and **malaise**, may be present, especially in more severe cases.
- **Lymphangitis:** Red streaks extending toward nearby lymph nodes may indicate the spread of infection through the lymphatic system.
- **Lymphadenopathy:** Swollen regional lymph nodes may be palpable.

Common Sites Affected:

- **Lower limbs:** The legs, particularly around the **shins**, **calves**, and **feet**, are the most common sites.
- **Face:** Can occur after trauma or dental infections.
- **Upper limbs:** Especially in cases of intravenous drug use or trauma.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is usually based on the clinical presentation of **erythema**, **swelling**, **warmth**, and **pain** in the affected area, with **ill-defined borders**.
- **Palpation:** The skin feels **warm** and **tender** to the touch, and there may be evidence of **induration** or **fluid collection** (e.g., abscess).

b) Blood Tests:

- **Full blood count (FBC):** An elevated **white blood cell count** (leukocytosis) indicates systemic infection.
- **C-reactive protein (CRP):** Raised CRP levels indicate inflammation or infection.
- **Erythrocyte sedimentation rate (ESR):** Often elevated in cellulitis, reflecting systemic inflammation.

c) Swab for Culture and Sensitivity:

- If there are **open wounds**, **blisters**, or **draining fluid**, a swab can be taken to identify the causative organism and guide antibiotic therapy.

d) Blood Cultures:

- Blood cultures are taken if the patient presents with signs of **systemic infection** (e.g., high fever, rigors) or is **immunocompromised** to rule out bacteraemia or sepsis.

e) Imaging:

- **Ultrasound:** Used to assess for **deep abscesses** or other complications.
- **CT scan:** May be required if **necrotizing fasciitis** is suspected, as cellulitis can mimic this more severe infection.

4. Explanation of Investigations:

- **Blood tests (FBC, CRP, ESR):** Help assess the **severity of infection** and monitor the body's inflammatory response.

- **Swab for culture:** Identifies the **causative organism** and determines its **antibiotic sensitivity**, important in cases of treatment failure or recurrence.
- **Blood cultures:** Necessary to rule out **septicaemia** in patients with systemic signs of infection.
- **Imaging:** Helpful when deeper infections (e.g., abscesses or necrotizing fasciitis) are suspected.

5. Diagnosis Criteria for Cellulitis:

Cellulitis is diagnosed based on **clinical findings**:

- **Diffuse erythema** and **swelling** with **poorly defined borders**.
- **Warmth** and **tenderness** in the affected area.
- **Systemic symptoms**, such as **fever** or **malaise**, may be present in more severe cases.
- Laboratory tests and imaging are used to support the diagnosis or exclude other conditions, such as **necrotizing fasciitis** or **deep vein thrombosis**.

6. First-Line Therapy According to Guidelines:

a) Oral Antibiotics (Mild to Moderate Cases):

1. **Flucloxacillin:**
 - First-line antibiotic for cellulitis caused by **Staphylococcus aureus** or **Streptococcus pyogenes**.
 - Adult dose: **500 mg four times daily** for **7-14 days**.
 - **Mechanism:** Beta-lactam antibiotic that inhibits bacterial cell wall synthesis.
2. **Penicillin V:**
 - Effective for cellulitis caused primarily by **Streptococcus pyogenes**.
 - Adult dose: **500 mg four times daily** for **7-10 days**.

b) Antibiotics for Penicillin-Allergic Patients:

1. **Clarithromycin:**
 - Used in patients allergic to penicillin.
 - Adult dose: **250-500 mg twice daily** for **7-14 days**.
 - **Mechanism:** Macrolide antibiotic that inhibits bacterial protein synthesis.
2. **Clindamycin:**
 - Another alternative for penicillin-allergic patients or in **severe infections**.
 - Adult dose: **300-450 mg four times daily** for **7-10 days**.

c) Intravenous Antibiotics (Severe or Systemic Cases):

- **Benzylpenicillin** or **Flucloxacillin:**
 - IV therapy for severe or systemic cellulitis.
 - Adult dose: **1.2 g every 6 hours** for **7-14 days**, depending on the severity of infection.
- **Ceftriaxone:** Used in cases of **severe infection** or if there is a concern for **penicillin allergy**.

d) Supportive Measures:

- **Elevation:** Elevating the affected limb helps reduce **swelling** and **oedema**.
- **Analgesia:** NSAIDs or **paracetamol** for pain and fever management.
- **Hydration:** Ensure adequate **fluid intake** to prevent dehydration.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Penicillin:** Contraindicated in patients with a **history of penicillin allergy**.

- **Flucloxacillin:** Avoid in penicillin-allergic patients.

b) Second-Line Therapy:

1. **Doxycycline:**
 - An alternative for **mild to moderate cellulitis**, especially if **MRSA** is suspected.
 - Adult dose: **100 mg twice daily** for **7-10 days**.
2. **Linezolid:**
 - Used for **severe or resistant infections** or if **MRSA** is confirmed.
 - Mechanism: Inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit.

8. Routine Monitoring and Follow-Up:

- **Response to treatment:** Symptoms should start improving within **48-72 hours** of starting antibiotics. If symptoms persist or worsen, further investigations are needed.
- **Complications:** Monitor for the development of complications such as **abscess formation, necrotizing fasciitis, or sepsis**.
- **Follow-up appointments:** Necessary to ensure complete resolution of the infection, particularly in immunocompromised patients or those with recurrent infections.

9. Complications:

1. **Abscess formation:**
 - If pus collects in the infected tissue, it can form an abscess requiring **incision and drainage**.
2. **Sepsis:**
 - Cellulitis can progress to sepsis, a life-threatening condition, especially in immunocompromised or elderly patients.
3. **Necrotizing fasciitis:**
 - A rapidly spreading infection of the deep fascia, which can be mistaken for cellulitis but requires urgent surgical intervention.
4. **Recurrent cellulitis:**
 - Chronic lymphedema, venous insufficiency, or skin trauma can predispose patients to recurrent cellulitis.
5. **Deep vein thrombosis (DVT):**
 - Cellulitis of the legs can mimic or coexist with DVT, so it's important to assess for signs of DVT (e.g., leg swelling, calf tenderness).

Summary of Key Points for Cellulitis:

- **Cellulitis** is a **bacterial skin infection** affecting the **dermis** and **subcutaneous tissue**, usually caused by **Staphylococcus aureus** or **Streptococcus pyogenes**.
- It presents with **diffuse erythema, swelling, warmth, and pain** with poorly defined borders.
- First-line treatment includes **oral flucloxacillin** or **penicillin V** for mild cases and **IV antibiotics** for more severe or systemic infections.

94. Necrotizing Fasciitis

1. Detailed Definition of Necrotizing Fasciitis:

Necrotizing fasciitis is a rapidly progressing, life-threatening **soft tissue infection** that involves the **fascia** and **subcutaneous tissues**, leading to **necrosis** (tissue death). It is often referred to as a "**flesh-eating disease**" due to its aggressive nature. Necrotizing fasciitis can occur

following minor trauma, surgery, or even spontaneously. Early recognition and urgent surgical intervention are critical for survival.

The condition can be caused by multiple organisms:

- **Type I: Polymicrobial infection** involving a mix of aerobic and anaerobic bacteria, including **Streptococcus**, **Staphylococcus**, **Enterobacteriaceae**, and **Bacteroides**.
- **Type II:** Typically caused by **group A Streptococcus (Streptococcus pyogenes)**, sometimes in combination with **Staphylococcus aureus**.
- **Type III: Clostridial myonecrosis** (gas gangrene) caused by **Clostridium perfringens**.

2. Common Presenting Complaints and Symptoms:

- **Sudden onset of pain:** Severe, disproportionate pain at the site of infection, which may initially appear as minor trauma or injury.
- **Swelling and erythema:** The skin becomes red, swollen, and warm, with rapidly spreading erythema. The infection progresses quickly and often extends beyond the visible area.
- **Crepitus:** In cases caused by gas-producing bacteria (e.g., *Clostridium* spp.), **crepitus** may be felt on palpation due to gas in the subcutaneous tissues.
- **Skin necrosis:** As the infection progresses, the skin may develop **blisters**, **bullae**, or turn **gray**, **purple**, or **black** as the tissue dies.
- **Fever and systemic toxicity:** Patients often have **fever**, **tachycardia**, and signs of **sepsis** (hypotension, confusion, multi-organ dysfunction).
- **Ecchymosis:** Bruising or purplish discoloration of the skin may develop.
- **Shock:** If untreated, necrotizing fasciitis leads to septic shock, characterized by **hypotension**, **altered mental status**, and **organ failure**.

Common Sites Affected:

- **Extremities:** Commonly affects the legs, particularly after trauma or surgery.
- **Abdomen:** May occur after abdominal surgery or in patients with intra-abdominal infections.
- **Perineum:** Necrotizing fasciitis of the perineum is known as **Fournier's gangrene**, typically seen in diabetic or immunocompromised patients.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection and palpation:** The hallmark of necrotizing fasciitis is **rapidly spreading erythema** with signs of skin necrosis (discoloration, blistering, crepitus). Palpation may reveal **tenderness**, **firm tissue**, or **gas in the tissue** (crepitus).
- **Assessment for systemic signs:** Look for signs of **sepsis**, such as fever, hypotension, and confusion.

b) Blood Tests:

- **Complete blood count (CBC):** Leukocytosis (elevated white blood cell count) is common.
- **C-reactive protein (CRP) and Erythrocyte sedimentation rate (ESR):** These inflammatory markers are often elevated in necrotizing fasciitis.
- **Lactate levels:** Elevated lactate is a sign of tissue hypoxia and sepsis.
- **Serum creatinine:** May be elevated in cases with multi-organ involvement or septic shock.

c) Imaging:

- **X-ray:** May show **gas in the soft tissues** in cases caused by gas-producing organisms (e.g., *Clostridium*).
- **CT scan:** Helps define the extent of soft tissue involvement and may reveal gas in the subcutaneous tissue, fluid collections, or fascial thickening.
- **MRI:** Useful for detecting **fascia involvement** and determining the spread of infection, especially in deep tissue planes.

d) Tissue Biopsy and Culture:

- **Surgical exploration:** The **gold standard** for diagnosis. **Tissue biopsy** is taken during debridement for **culture** and **histopathology** to confirm necrosis and identify the causative organism.
- **Blood cultures:** Performed to detect bacteraemia in patients with systemic signs of sepsis.

4. Explanation of Investigations:

- **Blood tests:** Leukocytosis and elevated inflammatory markers like CRP and ESR suggest systemic inflammation and infection. High lactate indicates tissue hypoxia.
- **Imaging:** X-rays and CT scans can reveal gas in the tissues, a key diagnostic feature in some cases of necrotizing fasciitis, especially with clostridial infections.
- **Tissue biopsy and culture:** Essential for identifying the specific **pathogen** involved and determining the **appropriate antibiotic therapy**.

5. Diagnosis Criteria for Necrotizing Fasciitis:

Necrotizing fasciitis is diagnosed based on **clinical suspicion**, supported by **imaging** and **surgical exploration**. The following features are crucial for diagnosis:

- **Rapid progression of soft tissue infection.**
- **Severe pain** that is out of proportion to the appearance of the lesion.
- **Systemic toxicity**, including fever, hypotension, and signs of sepsis.
- **Gas in tissues** (detected via imaging or palpation) in gas-producing bacterial infections.
- **Necrosis of fascia** confirmed through **surgical exploration** and **tissue biopsy**.

6. First-Line Therapy According to Guidelines:

Immediate and aggressive treatment is essential for necrotizing fasciitis. The mainstay of treatment is **surgical debridement**, combined with **broad-spectrum antibiotics** and **supportive care**.

a) Surgical Debridement:

- **Urgent surgical debridement** is the cornerstone of treatment and must be performed **as soon as necrotizing fasciitis is suspected**.
- The infected and necrotic tissue must be **completely excised**, and repeated debridement may be necessary until all necrotic tissue is removed.

b) Broad-Spectrum Antibiotics:

1. Carbapenem or Piperacillin-Tazobactam:

- **First-line empiric therapy** to cover a broad range of organisms, including gram-positive, gram-negative, and anaerobes.
- Dose: **Meropenem** (1g every 8 hours IV) or **Piperacillin-Tazobactam** (4.5g every 6 hours IV).

2. Clindamycin:

- Given for its **anti-toxin effects** in **group A Streptococcus** and **Staphylococcus aureus** infections.

- Dose: **600-900 mg IV every 8 hours**.
 - **Mechanism:** Inhibits bacterial protein synthesis and decreases toxin production.
3. **Vancomycin or Linezolid:**
- Added if **methicillin-resistant Staphylococcus aureus (MRSA)** is suspected.
 - Dose: **Vancomycin** (15-20 mg/kg IV every 8-12 hours) or **Linezolid** (600 mg IV every 12 hours).

c) Supportive Care:

- **Intravenous fluids:** Aggressive fluid resuscitation is required to treat shock and prevent dehydration.
- **Vasopressors:** In cases of septic shock, **vasopressors** like **norepinephrine** may be required to maintain blood pressure.
- **Pain management:** Adequate analgesia, including opioids, is necessary to control the severe pain associated with necrotizing fasciitis.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Surgical delay:** Delaying surgery can be life-threatening, as necrotizing fasciitis progresses rapidly and leads to tissue destruction.
- **Penicillin allergy:** For patients with a history of severe penicillin allergy, alternatives such as **linezolid** or **daptomycin** can be used instead of **carbapenem** or **piperacillin-tazobactam**.

b) Second-Line Therapy:

- **Hyperbaric oxygen therapy:**
 - May be used as an adjunct in some cases, particularly when **Clostridium** species are involved.
 - Hyperbaric oxygen enhances **oxygenation** in the tissues and helps to kill anaerobic bacteria.

8. Routine Monitoring and Follow-Up:

- **Monitoring post-surgery:** Patients should be monitored in an **intensive care unit (ICU)**, especially if they show signs of septic shock or organ failure.
- **Repeated debridement:** Surgical wounds must be re-evaluated frequently, and repeated debridement may be necessary.
- **Blood tests and cultures:** Monitor for the resolution of infection with **serial blood tests** and **blood cultures**.
- **Wound care:** Long-term wound care, including the use of **negative pressure wound therapy (NPWT)**, may be required to promote healing of large wounds after extensive debridement. Skin grafting may be necessary once the infection is controlled.
- **Monitoring for complications:** Given the high risk of **sepsis**, **acute kidney injury**, and **multi-organ failure**, patients require close monitoring of **vital signs**, **renal function**, **liver function**, and **coagulation status**.
- **Rehabilitation:** In cases with extensive tissue damage or amputation, rehabilitation may be necessary, including physical therapy and psychological support for recovery from the trauma of the illness.

9. Complications:

1. **Sepsis and Septic Shock:**

- Necrotizing fasciitis often leads to **sepsis**, characterized by widespread infection, systemic inflammation, and multi-organ failure. Early intervention with **fluids, antibiotics, and surgical debridement** is crucial to prevent septic shock.
- 2. **Amputation:**
 - If the infection is extensive and tissue destruction is irreversible, **amputation** of the affected limb may be required to prevent the spread of infection and save the patient's life.
- 3. **Multi-Organ Failure:**
 - Necrotizing fasciitis can rapidly lead to **multi-organ failure**, including **acute respiratory distress syndrome (ARDS), renal failure, and liver dysfunction** due to the overwhelming systemic infection.
- 4. **Death:**
 - Mortality rates for necrotizing fasciitis can be as high as **20-40%**, especially in cases where treatment is delayed, or the patient has underlying **comorbidities** such as diabetes, immunosuppression, or advanced age.
- 5. **Long-term disability:**
 - Extensive tissue loss, scarring, and possible amputations can result in **physical disabilities**, requiring long-term rehabilitation and support.

Summary of Key Points for Necrotizing Fasciitis:

- **Necrotizing fasciitis** is a rapidly progressing, life-threatening soft tissue infection that involves the **fascia** and **subcutaneous tissue**.
- It is characterized by **severe pain, rapid spread of infection, erythema, swelling**, and, in some cases, **skin necrosis** and **crepitus**.
- **Urgent surgical debridement** is the cornerstone of treatment, along with **broad-spectrum antibiotics** (e.g., **carbapenem, clindamycin, vancomycin** for MRSA coverage).
- Early recognition and intervention are critical to improving outcomes, as the disease can lead to **sepsis, shock, multi-organ failure**, and death.
- Patients require close monitoring in the **ICU** for systemic complications, and **long-term wound care** and **rehabilitation** are often necessary due to extensive tissue damage.

95. Folliculitis

1. Detailed Definition of Folliculitis:

Folliculitis is the inflammation of the **hair follicles**, most commonly caused by **bacterial or fungal infections**, but it can also result from physical irritation, occlusion, or other factors. It is usually a benign and self-limiting condition but can cause discomfort and may occasionally lead to deeper infections like **furuncles** or **carbuncles**.

Folliculitis can be classified into:

- **Superficial folliculitis:** Involves the upper portion of the hair follicle.
- **Deep folliculitis:** Involves the entire hair follicle and can lead to more severe inflammation and abscess formation.

2. Common Presenting Complaints and Symptoms:

- **Red papules or pustules:** Small, red bumps or pustules centered around hair follicles. They may have a small white or yellow pustule at the tip.
- **Itching or tenderness:** The affected areas may be itchy, tender, or slightly painful.

- **Clusters of lesions:** Folliculitis often occurs in clusters, especially in areas prone to friction or occlusion.
- **Post-inflammatory hyperpigmentation:** In patients with darker skin, folliculitis may leave behind **hyperpigmented** spots after the inflammation resolves.

Common Sites Affected:

- **Beard area (sycosis barbae):** In men, folliculitis commonly affects the beard area due to shaving.
- **Scalp:** Common in both adults and children.
- **Buttocks and thighs:** Often affected due to friction and sweat.
- **Axillae:** Areas of moisture and hair, making them prone to bacterial overgrowth.
- **Back:** Especially in patients with acne-prone skin.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is typically clinical, based on the appearance of **papules** or **pustules** surrounding hair follicles. Examine common sites like the scalp, face, and axillae.
- **History:** Obtain a detailed history regarding recent **shaving**, **hot tub use**, **sweating**, or exposure to **irritating substances** that may predispose to folliculitis.

b) Bacterial Swab:

- A **swab** may be taken from the pustules for **culture** to identify the causative organism, especially in cases of recurrent or resistant folliculitis. Common bacteria include **Staphylococcus aureus**.

c) Fungal Culture:

- If fungal folliculitis is suspected (e.g., **Malassezia** or **Candida** species), a **fungal culture** or **KOH preparation** may be indicated.

d) Blood Tests (if systemic involvement):

- In severe or deep folliculitis, **complete blood count (CBC)** may reveal leukocytosis, and **CRP** may be elevated, indicating systemic inflammation or infection.

4. Explanation of Investigations:

- **Swab for bacterial culture:** Identifies the specific bacteria causing the infection, particularly in recurrent or persistent cases. **Staphylococcus aureus** is the most common pathogen.
- **Fungal culture:** Used to identify **fungal causes** of folliculitis, particularly in immunocompromised patients or in areas with chronic moisture (e.g., scalp, axilla).
- **Blood tests:** Useful in severe cases to rule out systemic infection.

5. Diagnosis Criteria for Folliculitis:

Folliculitis is diagnosed clinically based on:

- The presence of **erythematous papules** or **pustules** centered on hair follicles.
- The typical distribution in areas of **moisture**, **friction**, or **shaving**.
- A swab or culture may confirm **Staphylococcus aureus**, **Pseudomonas** (in hot tub folliculitis), or a fungal pathogen.

6. First-Line Therapy According to Guidelines:

Treatment depends on the **severity**, **cause**, and **location** of the folliculitis. Most cases resolve spontaneously or with minimal intervention.

a) Topical Therapy (Mild Cases):

1. Topical Antibacterial Agents:

- **Topical Mupirocin** or **Fusidic Acid** cream is commonly used for **localized folliculitis** caused by **Staphylococcus aureus**.
- **Application:** Applied **2-3 times daily** for **5-7 days**.
- **Mechanism:** Inhibits bacterial protein synthesis and is effective against **Staphylococcus aureus**.

2. Benzoyl Peroxide Washes:

- Useful in reducing the bacterial load on the skin and preventing the recurrence of folliculitis.
- **Mechanism:** Has both **antibacterial** and **keratolytic properties**, helping to reduce the growth of **Propionibacterium acnes** and other bacteria.

b) Oral Antibiotics (Moderate to Severe Cases or Deep Folliculitis):

1. Oral Flucloxacillin:

- Used for more **extensive** or **deep infections** where topical treatments are insufficient.
- Adult dose: **500 mg four times daily** for **7-10 days**.
- **Mechanism:** A beta-lactam antibiotic that targets bacterial cell wall synthesis, effective against **Staphylococcus aureus**.

2. Oral Doxycycline:

- An option in cases of recurrent or persistent folliculitis, or if MRSA is suspected.
- Adult dose: **100 mg twice daily** for **7-10 days**.
- **Mechanism:** Inhibits bacterial protein synthesis, effective against **MRSA**.

c) Antifungal Treatment (Fungal Folliculitis):

1. Topical Clotrimazole or Ketoconazole:

- For fungal causes of folliculitis, such as **Malassezia** or **Candida**.
- Applied **2-3 times daily** for **1-2 weeks**.
- **Mechanism:** Inhibits fungal cell membrane synthesis by targeting **ergosterol**.

2. Oral Itraconazole:

- Used for more extensive or resistant cases of **fungal folliculitis**.
- Adult dose: **100-200 mg once daily** for **7-14 days**.
- **Mechanism:** Inhibits ergosterol synthesis in fungal cell membranes.

d) General Measures:

- **Good hygiene:** Regular cleansing of affected areas with antibacterial soap.
- **Avoidance of irritants:** Discontinue or modify **shaving practices**, avoid tight clothing, and limit exposure to **hot tubs**.
- **Antibacterial body washes:** Using chlorhexidine or benzoyl peroxide washes regularly can help prevent recurrence.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Topical antibiotics:** May not be sufficient for **deep** or **widespread infections**, requiring systemic antibiotics.
- **Flucloxacillin:** Contraindicated in patients with a **penicillin allergy**.

b) Second-Line Therapy:

1. Oral Clindamycin:

- For **refractory cases** of bacterial folliculitis or when MRSA is suspected.
- Adult dose: **300-450 mg four times daily** for **7-10 days**.

- **Mechanism:** Inhibits bacterial protein synthesis and is effective against **Staphylococcus aureus** and **Streptococcus**.
2. **Laser Hair Removal:**
- In cases of **recurrent folliculitis**, especially in areas prone to irritation (e.g., beard area), laser hair removal may help reduce the density of hair follicles and prevent further infections.

8. Routine Monitoring and Follow-Up:

- **Resolution of lesions:** Most cases of folliculitis resolve with treatment in **1-2 weeks**. Monitor for any persistent or worsening symptoms.
- **Preventing recurrence:** Patients should be educated on the importance of **hygiene**, modifying **shaving practices**, and using **antibacterial washes** to prevent recurrences.
- **Culture results:** If swabs or cultures are taken, follow up with appropriate changes in antibiotics based on sensitivity results, particularly in resistant cases or fungal infections.

9. Complications:

1. **Furunculosis:**
 - Untreated or severe folliculitis can progress to **furunculosis**, where infection extends deeper into the skin, forming **boils** (furuncles) or abscesses.
2. **Carbuncles:**
 - Clusters of furuncles can coalesce into a larger infection, forming **carbuncles**, which require more aggressive treatment, including possible surgical drainage.
3. **Scarring and hyperpigmentation:**
 - Chronic or deep folliculitis may lead to **scarring** or **post-inflammatory hyperpigmentation**, especially in darker skin types.
4. **Spread of infection:**
 - Folliculitis, if left untreated, may spread to other parts of the skin or enter the bloodstream, leading to **systemic infection**.

Summary of Key Points for Folliculitis (continued):

- **Folliculitis** is an inflammation or infection of the **hair follicles**, typically caused by **Staphylococcus aureus** or **fungal organisms**, but it can also result from physical irritation or occlusion.
- It presents with **red papules or pustules** cantered around hair follicles, often associated with **itching** or **tenderness**.
- **Topical antibiotics** (e.g., **mupirocin** or **fusidic acid**) are effective for mild cases, while **oral antibiotics** (e.g., **flucloxacillin** or **doxycycline**) are indicated for more extensive or deep infections.
- **Fungal folliculitis** requires **antifungal treatment**, such as **topical clotrimazole** or **oral itraconazole**.
- Good **hygiene practices** and **avoiding irritants** (such as tight clothing or hot tubs) can help prevent recurrence.
- Complications include **furunculosis**, **carbuncles**, **scarring**, and, in rare cases, **systemic infection**.

96. Herpes Simplex Virus (HSV)

1. Detailed Definition of Herpes Simplex Virus (HSV):

Herpes simplex virus (HSV) is a common viral infection that causes **recurrent vesicular eruptions** on the skin and mucous membranes. HSV is divided into two types:

- **HSV-1:** Primarily responsible for **oral herpes** (cold sores), but it can also cause genital infections.
- **HSV-2:** Primarily responsible for **genital herpes**, though it can also affect the orofacial region.

Both HSV-1 and HSV-2 establish **latent infections** in the host's **nerve ganglia** and can reactivate later, causing recurrent outbreaks.

2. Common Presenting Complaints and Symptoms:

a) Oral Herpes (HSV-1):

- **Cold sores (fever blisters):** Painful **vesicles** or **blisters** that appear on or around the lips. These vesicles rupture and form **crusts** before healing.
- **Prodrome:** Patients may report a **tingling, itching, or burning** sensation before the vesicles appear.
- **Recurrent episodes:** Outbreaks may recur with triggers such as **stress, illness, sun exposure, or immunosuppression**.

b) Genital Herpes (HSV-2):

- **Painful genital ulcers:** Vesicles that rupture to form **shallow, painful ulcers** on the genital mucosa.
- **Dysuria:** Pain or burning during urination in patients with genital involvement.
- **Inguinal lymphadenopathy:** Swollen lymph nodes in the groin area.
- **Systemic symptoms:** Fever, malaise, and muscle aches during the **primary infection**.
- **Recurrence:** Recurrent outbreaks tend to be milder and shorter in duration than the primary infection.

c) Herpetic Whitlow:

- **Vesicular lesions** on the fingers or around the nails, usually seen in healthcare workers or patients who come into contact with HSV-1 or HSV-2.

d) Herpes Keratitis:

- **Ocular herpes infection** involving the **cornea**, causing eye pain, photophobia, and vision changes.

e) Neonatal Herpes:

- Can occur if a mother with active **genital herpes** transmits the virus to her infant during delivery, leading to serious complications such as **disseminated infection, encephalitis, or skin-eye-mouth (SEM) disease**.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis of HSV is primarily clinical, based on the appearance of **vesicular lesions** that rupture and form **ulcers**.
- **History of recurrence:** Ask about previous outbreaks or triggering factors such as stress, illness, or sun exposure.

b) Laboratory Tests:

1. **Viral swab for HSV PCR:**
 - **Polymerase chain reaction (PCR)** test is the most sensitive method to detect **HSV DNA** in swabbed fluid from a vesicle or ulcer.
2. **Viral culture:**

- Less commonly used than PCR but may be done for active lesions to isolate the virus.
- 3. **Direct fluorescent antibody (DFA) testing:**
 - A rapid test used to detect HSV antigens directly from lesion swabs.
- 4. **Tzanck smear:**
 - Microscopic examination of vesicle fluid or base scrapings for **multinucleated giant cells**, which is characteristic of HSV but not specific (also seen in **varicella-zoster virus**).
- 5. **Serology:**
 - Blood tests to detect **HSV antibodies** (IgG and IgM). These tests are useful for identifying previous exposure but are not helpful for acute diagnosis.

4. Explanation of Investigations:

- **HSV PCR:** A highly sensitive and specific test to detect **HSV DNA** in vesicular fluid, the preferred test for active lesions.
- **Viral culture:** Can isolate the virus but has lower sensitivity, especially in healed lesions.
- **Tzanck smear:** Identifies **multinucleated giant cells** under microscopy, a hallmark of HSV infection but not specific to HSV.
- **Serology:** Detects antibodies, which can indicate past infection but are not useful in diagnosing active outbreaks.

5. Diagnosis Criteria for Herpes Simplex Virus:

The diagnosis of HSV infection is based on a combination of **clinical presentation** and **laboratory findings**. Key diagnostic criteria include:

- **Painful vesicles or ulcers** on the oral or genital mucosa.
- **Positive HSV PCR** or **viral culture** from a lesion.
- A history of **recurrence** triggered by stress or immunosuppression supports the diagnosis of HSV.

6. First-Line Therapy According to Guidelines:

a) Antiviral Therapy:

1. **Oral Acyclovir:**
 - First-line treatment for **HSV infections**.
 - Dosage for oral herpes: **200 mg five times daily** for **5-10 days**.
 - Dosage for genital herpes: **400 mg three times daily** for **7-10 days** (primary infection), or **400 mg twice daily** for **5 days** (recurrent infections).
 - **Mechanism:** Inhibits viral DNA polymerase, preventing viral replication.
2. **Valacyclovir:**
 - An alternative to acyclovir with better **bioavailability**.
 - Dosage for oral herpes: **2 g twice daily** for **1 day** (recurrent episodes).
 - Dosage for genital herpes: **500 mg twice daily** for **3-5 days**.
 - **Mechanism:** Prodrug of acyclovir that converts to acyclovir in the body.
3. **Famciclovir:**
 - Another option for HSV treatment.
 - Dosage for oral herpes: **1500 mg once** for **recurrent outbreaks**.
 - Dosage for genital herpes: **250 mg three times daily** for **5 days** (recurrent infections).

b) Topical Therapy:

- **Topical Acyclovir cream** or **Penciclovir**: May be used for minor **oral herpes lesions**, but oral antiviral therapy is generally more effective for moderate to severe cases.

c) Suppressive Therapy (for Frequent Recurrences):

- For patients with frequent recurrences (e.g., >6 outbreaks/year), **daily suppressive therapy** with **oral acyclovir** (400 mg twice daily) or **valacyclovir** (500 mg once daily) can reduce the frequency and severity of outbreaks.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Acyclovir hypersensitivity**: Patients with known **allergic reactions** to acyclovir or related antiviral agents should not take these drugs.

b) Second-Line Therapy:

1. Foscarnet:

- Used in cases of **acyclovir-resistant HSV** (often seen in immunocompromised patients).
- **Mechanism**: Inhibits viral DNA polymerase directly without requiring activation by viral kinases.

2. Cidofovir:

- Another antiviral option for **acyclovir-resistant HSV**.
- **Mechanism**: A nucleotide analogue that inhibits viral DNA polymerase.

8. Routine Monitoring and Follow-Up:

- **Symptom improvement**: Monitor for the resolution of lesions and symptoms within **5-7 days** of starting antiviral therapy.
- **Recurrence monitoring**: Educate patients about potential triggers and advise on suppressive therapy if they experience frequent recurrences.
- **Complications**: Patients should seek immediate care if they develop **severe or systemic symptoms**, such as **encephalitis** or **disseminated HSV**.

9. Complications:

1. Herpetic Whitlow:

- HSV infection of the fingers, commonly seen in healthcare workers or those in contact with the virus.

2. Herpes Simplex Encephalitis:

- A serious complication, particularly caused by **HSV-1**, characterized by fever, headache, and neurological deficits.
- Requires urgent **IV acyclovir** treatment.

3. Disseminated HSV infection:

- Occurs in immunocompromised patients, leading to widespread skin involvement and systemic symptoms.

4. Neonatal Herpes:

- Can be life-threatening, with a risk of **neurological damage** or death. Requires prompt antiviral therapy for both the mother and infant.

Summary of Key Points for Herpes Simplex Virus:

- **Herpes simplex virus (HSV)** causes **painful vesicular eruptions** on the **oral** or **genital mucosa** and is highly **contagious**.

- **Oral herpes** (HSV-1) typically presents with **cold sores**, while **genital herpes** (HSV-2) leads to painful genital ulcers.
- **PCR testing** is the gold standard for diagnosing HSV, and treatment involves **oral antiviral agents** such as **acyclovir**, **valacyclovir**, or **famciclovir**.
- **Suppressive therapy** is recommended for patients with frequent recurrences, and complications include **encephalitis**, **herpetic whitlow**, and **

97. Varicella Zoster Virus (VZV)

1. Detailed Definition of Varicella Zoster Virus (VZV):

Varicella Zoster Virus (VZV) is a highly contagious herpesvirus responsible for two distinct clinical conditions:

- **Varicella (chickenpox):** The primary infection, commonly occurring in childhood and characterized by a pruritic vesicular rash.
- **Herpes Zoster (shingles):** The reactivation of latent VZV in the sensory ganglia, occurring later in life and presenting as a painful, dermatomal vesicular rash.

Following the primary varicella infection, the virus remains dormant in the **dorsal root ganglia** or **cranial nerve ganglia** and may reactivate years later as **shingles**.

2. Common Presenting Complaints and Symptoms:

a) Varicella (Chickenpox):

- **Pruritic vesicular rash:** The rash begins as **macules**, progresses to **papules**, and then forms **vesicles** (fluid-filled blisters) that eventually crust over. The lesions appear in "crops" over a period of days.
- **Fever and malaise:** Common systemic symptoms, particularly in children.
- **Distribution:** The rash typically starts on the **trunk** and spreads to the **face**, **scalp**, and **extremities**.
- **Oral ulcers:** Vesicles can also appear on the **mucous membranes** of the mouth and pharynx.
- **Mild lymphadenopathy:** Enlarged lymph nodes may occur in response to infection.

b) Herpes Zoster (Shingles):

- **Painful dermatomal rash:** A unilateral, painful vesicular rash following a **single dermatome**, typically affecting the **thorax** or **face**.
- **Prodrome:** Pain, burning, or tingling may precede the rash by **1-5 days**.
- **Postherpetic neuralgia:** Persistent pain in the affected dermatome after the rash has resolved, lasting for weeks, months, or even years.
- **Ophthalmic involvement:** Involvement of the **trigeminal nerve (V1)** can cause **herpes zoster ophthalmicus**, which can lead to **corneal scarring** or **vision loss**.
-

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis of **varicella** is clinical, based on the appearance of **multiple stages of lesions** (macules, papules, vesicles, crusts) in different areas of the body. For **herpes zoster**, a unilateral vesicular rash following a **dermatomal distribution** is characteristic.
- **History of chickenpox:** In cases of shingles, ask about a prior history of **varicella** infection.

b) Laboratory Tests:

1. **VZV PCR:**

- The **gold standard** for diagnosing both varicella and herpes zoster. Swabs of vesicular fluid or lesion scrapings are tested for **VZV DNA**.
- 2. **Direct fluorescent antibody (DFA) testing:**
 - Rapid detection of VZV antigens from vesicular fluid or scrapings, useful in confirming varicella or shingles.
- 3. **Tzanck smear:**
 - Identifies **multinucleated giant cells**, which are characteristic of herpesvirus infections but not specific to VZV.
- 4. **Serology (IgG and IgM antibodies):**
 - Can be used to determine immune status in those with uncertain exposure histories. **IgM antibodies** indicate recent infection, while **IgG antibodies** reflect past infection or vaccination.

c) Imaging (for shingles-related complications):

- **MRI or CT scan** may be necessary to assess for **neurological complications** in cases of **zoster-related encephalitis** or **cranial nerve involvement**.

4. Explanation of Investigations:

- **VZV PCR:** A highly sensitive and specific method for detecting **VZV DNA** from vesicular lesions, allowing for accurate diagnosis in both varicella and zoster.
- **Tzanck smear:** Identifies **giant cells**, a sign of herpesvirus infection, though not specific to VZV.
- **Serology:** Helps determine past exposure or vaccination status, especially in individuals with no clear history of chickenpox or vaccination.

5. Diagnosis Criteria for Varicella Zoster Virus:

Varicella is diagnosed based on:

- The presence of a **pruritic, vesicular rash** that evolves in **stages** from macules to vesicles to crusts.
- A history of **exposure** to the virus (e.g., contact with an infected person).
- Positive **PCR** from a vesicular swab.

Herpes Zoster (shingles) is diagnosed based on:

- The presence of a **unilateral vesicular rash** restricted to a **single dermatome**, often with **severe pain**.
- A history of **prior varicella infection** or exposure.
- Positive **PCR** from a lesion or **clinical features** alone in typical cases.

6. First-Line Therapy According to Guidelines:

a) Antiviral Therapy:

1. **Oral Acyclovir** (for chickenpox and shingles):
 - **Varicella:** Indicated for adults, adolescents, or immunocompromised patients.
 - Dosage for varicella: **800 mg five times daily** for **5-7 days**.
 - Dosage for shingles: **800 mg five times daily** for **7-10 days**.
 - **Mechanism:** Inhibits viral DNA polymerase, preventing viral replication.
2. **Valacyclovir:**
 - Better bioavailability than acyclovir and used for both **varicella** and **herpes zoster**.
 - Dosage for shingles: **1 g three times daily** for **7-10 days**.
 - **Mechanism:** Prodrug of acyclovir, converted to acyclovir in the body.

3. Famciclovir:

- An alternative to acyclovir with good efficacy for **shingles**.
- Dosage for shingles: **500 mg three times daily** for **7 days**.

b) Symptomatic Treatment:

- **Antihistamines:** Used to alleviate **itching** in varicella.
- **Analgesia:** NSAIDs or paracetamol for managing **pain** in shingles or varicella. **Opioids** may be necessary for severe pain in **postherpetic neuralgia**.

c) Corticosteroids (for shingles with severe pain):

- Short courses of **prednisolone** may be given to reduce **inflammation** and **pain** in severe cases of shingles, particularly in patients with **cranial nerve involvement**.

d) Varicella Zoster Immune Globulin (VZIG):

- Indicated for **post-exposure prophylaxis** in high-risk individuals (e.g., pregnant women, neonates, or immunocompromised individuals) who have been exposed to **varicella**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Acyclovir:** Contraindicated in patients with **known hypersensitivity** to acyclovir or valacyclovir.

b) Second-Line Therapy:

1. Foscarnet:

- Used in cases of **acyclovir-resistant VZV**, particularly in immunocompromised patients.
- **Mechanism:** Inhibits viral DNA polymerase directly without requiring activation by viral kinases.

2. Postherpetic Neuralgia Management**:

- **Gabapentin** or **pregabalin** for neuropathic pain in **postherpetic neuralgia**.
- **Tricyclic antidepressants** (e.g., amitriptyline) may also be effective for persistent pain.

8. Routine Monitoring and Follow-Up:

- **Resolution of lesions:** Monitor for healing of vesicles in **7-10 days**. Crusting typically signals the end of infectiousness in both **varicella** and **herpes zoster**.
- **Complications:** Follow up for possible complications like **secondary bacterial infection, pneumonia, or neurological involvement** (e.g., encephalitis, myelitis) in both varicella and shingles.
- **Postherpetic neuralgia:** Follow up with patients after shingles to assess for the development of **chronic pain**, which may require **neuropathic pain management**.

9. Complications:

1. Secondary Bacterial Infection:

- Varicella lesions, especially in children, may become **superinfected** with **Staphylococcus** or **Streptococcus**, requiring antibiotics.

2. Varicella Pneumonia:

- A rare but serious complication, more common in **adults** and **immunocompromised** patients. Presents with **cough, dyspnea, and fever**.

3. Herpes Zoster Ophthalmicus:

- Involvement of the **ophthalmic branch** of the trigeminal nerve (V1), leading to **painful eye involvement, conjunctivitis, keratitis**, and possible **vision loss** if untreated.
 - Immediate referral to an ophthalmologist and **antiviral therapy** (e.g., acyclovir or valacyclovir) are essential.
4. **Postherpetic Neuralgia:**
- Persistent **neuropathic pain** in the dermatome affected by shingles, lasting for weeks, months, or even years after the rash resolves. It is more common in older adults and can significantly impair quality of life.
 - Treated with **gabapentin, pregabalin, or tricyclic antidepressants** (e.g., amitriptyline).
5. **Disseminated VZV Infection:**
- Occurs in **immunocompromised** patients, with the virus spreading to the lungs, liver, and brain, leading to **pneumonitis, hepatitis, and encephalitis**.
 - Requires aggressive **IV antiviral therapy** and hospitalization.
6. **Encephalitis:**
- Varicella and herpes zoster can lead to **viral encephalitis**, especially in **immunocompromised** patients or neonates.
 - Presents with **fever, headache, altered mental status, and seizures**.
7. **Congenital Varicella Syndrome:**
- Occurs when a pregnant woman contracts varicella, particularly in the first 20 weeks of pregnancy, leading to **congenital anomalies** such as **limb hypoplasia, neurological abnormalities, and skin scarring** in the neonate.

Summary of Key Points for Varicella Zoster Virus:

- **Varicella Zoster Virus (VZV)** causes **varicella (chickenpox)** as the primary infection and **herpes zoster (shingles)** upon reactivation later in life.
- **Varicella** presents with a **pruritic vesicular rash** appearing in **crops**, while **herpes zoster** is characterized by a **painful, dermatomal vesicular rash**.
- **PCR testing** is the gold standard for diagnosing VZV, and treatment with **oral antivirals** (e.g., acyclovir, valacyclovir) is recommended, particularly in **immunocompromised** patients or those with severe disease.
- Complications include **secondary bacterial infections, varicella pneumonia, postherpetic neuralgia**, and **ophthalmic involvement** in herpes zoster.
- **Postherpetic neuralgia** can be treated with **neuropathic pain medications**, and severe complications like **encephalitis** or **disseminated infection** require urgent antiviral therapy and hospitalization.

98. Viral Warts

1. Detailed Definition of Viral Warts:

Viral warts are benign, raised growths on the skin caused by infection with **human papillomavirus (HPV)**. These lesions are typically harmless but can be cosmetically undesirable and, in some cases, painful. Viral warts are common in children and young adults but can affect individuals of any age. They spread through **direct skin contact** or **contaminated surfaces** and are more likely to occur in areas of skin trauma or moisture.

There are several types of viral warts, including:

- **Common warts (verruca vulgaris):** Typically found on the hands and fingers.
- **Plantar warts (verrucae plantaris):** Found on the soles of the feet.

- **Flat warts (verruca plana):** Smaller, smoother warts often found on the face, neck, or hands.
- **Filiform warts:** Long, thin warts often found on the face, particularly around the mouth or eyes.
- **Genital warts (condyloma acuminata):** Found on the genital or perianal areas, caused by specific types of HPV.

2. Common Presenting Complaints and Symptoms:

- **Small, raised growths:** Warts are typically well-demarcated, with a rough surface. They can vary in size and number and may appear as single lesions or in clusters.
- **Asymptomatic or painful:** While most warts are asymptomatic, **plantar warts** on the soles of the feet can be painful due to the pressure exerted when walking.
- **Black dots:** These are **thrombosed capillaries** seen on the surface of the warts, particularly in common warts.
- **Rough texture:** The surface of the wart feels rough and may have a cauliflower-like appearance, especially in common and plantar warts.
- **Location:** Common warts are often found on the **hands, fingers, knees, or elbows**, while plantar warts appear on the **soles** of the feet and flat warts can appear on the **face and neck**.
- **Genital warts** are usually found in the **anogenital region** and may cause discomfort, itching, or irritation.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis of viral warts is usually clinical, based on the characteristic appearance of raised, **rough-surfaced lesions**.
- **Examination of the skin:** Inspect the affected areas for the presence of warts, noting their size, number, location, and type (e.g., common warts, plantar warts, genital warts).

b) Dermatoscopy:

- **Dermatoscopic examination** can help differentiate warts from other skin conditions such as **seborrheic keratosis** or **skin tags**. A hallmark of warts under dermatoscopy is the presence of **thrombosed capillaries** (black dots).

c) Histopathology (rarely required):

- In cases where the diagnosis is uncertain or the wart is resistant to treatment, a **skin biopsy** may be performed for **histopathological analysis**. The biopsy will show **epidermal hyperplasia, koilocytosis, and inclusion bodies**, all characteristic of HPV infection.

4. Explanation of Investigations:

- **Clinical examination:** Most warts are diagnosed based on their appearance, and no further tests are usually needed.
- **Dermatoscopy:** Can confirm the presence of thrombosed capillaries (a key feature of viral warts), helping to differentiate warts from other skin lesions.
- **Biopsy:** Not routinely performed but may be indicated if a lesion is atypical or resistant to standard treatments.

5. Diagnosis Criteria for Viral Warts:

Viral warts are diagnosed clinically based on:

- The presence of **small, raised growths** with a **rough surface**, usually on the hands, feet, or other common areas affected by HPV.
- **Black dots** (thrombosed capillaries) visible on the wart's surface.
- **Dermatoscopy** revealing features consistent with warts, such as **vascular structures** or **capillary loops**.

6. First-Line Therapy According to Guidelines:

Treatment is not always necessary for viral warts, as many warts resolve spontaneously within **months to years**. However, treatment is often sought for cosmetic reasons, discomfort, or in cases of persistent warts.

a) Topical Therapies:

1. **Salicylic Acid (15-40%):**
 - Most common first-line treatment for viral warts.
 - Applied **daily** for several weeks or months.
 - **Mechanism:** Exfoliates the affected skin, softens the wart, and gradually destroys the infected tissue.
 - Requires **soaking** the wart in warm water before applying and removing dead skin regularly with a pumice stone or emery board.
2. **Cryotherapy:**
 - Freezing the wart with **liquid nitrogen**. Can be performed every **2-3 weeks** for several sessions.
 - **Mechanism:** Freezing causes **cell destruction** and stimulates an immune response to the virus.
 - Can cause **blisters** and **scarring**, especially in darker skin types.

b) Alternative Treatments:

1. **Cantharidin:**
 - A blistering agent applied to the wart by a healthcare provider.
 - The wart blisters and falls off within **1-2 weeks**.
 - **Mechanism:** Causes localized blistering, which removes the wart.
2. **Imiquimod** (for genital warts):
 - A topical **immune response modifier**.
 - Applied **3 times a week** for up to **16 weeks**.
 - **Mechanism:** Stimulates the immune system to fight the virus.
3. **Podophyllotoxin** (for genital warts):
 - Applied to the warts **twice daily for 3 days** a week for several weeks.
 - **Mechanism:** Inhibits viral replication and causes cell death in the wart tissue.

c) Oral and Systemic Therapies (for resistant cases):

1. **Oral Cimetidine:**
 - An **H2-blocker** that has immunomodulatory effects.
 - May be used off-label for **multiple or recalcitrant warts**.
2. **Laser therapy:**
 - Used in resistant cases or for **large warts**.
 - Uses focused light to destroy the wart tissue.
3. **Electrosurgery and Curettage:**
 - Physically removes the wart using **electrical current** or **scraping**. This method may be considered for **large** or **persistent warts**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Salicylic acid:** Avoid in patients with **diabetes** or **peripheral vascular disease**, especially for **plantar warts**, as it may cause skin damage or infection.
- **Cryotherapy:** Can cause **hypopigmentation** or **scarring**, particularly in darker skin types.

b) Second-Line Therapy:

1. **Imiquimod:**
 - Used for genital warts and resistant warts elsewhere, particularly in **immunocompromised** patients.
 - May also be used in conjunction with other treatments like **cryotherapy**.
2. **Pulsed-dye laser:**
 - Can be used for resistant warts by targeting the blood supply to the wart, leading to tissue death.

8. Routine Monitoring and Follow-Up:

- **Response to treatment:** Warts often require several weeks to months to resolve completely. Monitor for the reduction in wart size and the formation of healthy skin.
- **Recurrence:** Even after successful treatment, warts may recur, particularly in areas prone to trauma (e.g., hands, feet).
- **Side effects:** Follow up to ensure there are no adverse effects from treatments, such as **scarring**, **pain**, or **hyperpigmentation**.

9. Complications:

1. **Recurrence:**
 - Even after treatment, warts can recur due to the persistence of **latent HPV** in the surrounding skin.
2. **Scarring:**
 - Treatments like **cryotherapy**, **electrosurgery**, or **laser therapy** may lead to **scarring** or **changes in skin pigmentation**.
3. **Pain:**
 - **Plantar warts** can become **painful**, especially when they are on weight-bearing areas of the feet, making walking difficult.
4. **Secondary infection:**
 - Trauma to the wart through **scratching** or improper treatment can lead to a **secondary bacterial infection**.

Summary of Key Points for Viral Warts:

- **Viral warts** are caused by **HPV** and present as **small, raised, rough-surfaced growths** on the skin, typically on the hands, feet, or genital areas.
- Most cases are diagnosed **clinically**, though **dermatoscopy** or **biopsy** can be used in atypical cases.

99. Fungal Infections

1. Detailed Definition of Fungal Infections:

Fungal infections, also known as **mycoses**, are infections caused by fungi. They can affect the skin, nails, hair, mucous membranes, or internal organs. Fungal infections are broadly classified into:

- **Superficial mycoses:** Affect the skin, hair, or nails (e.g., **tinea**, **onychomycosis**).

- **Mucosal mycoses:** Affect mucous membranes (e.g., **oral thrush**, **vaginal candidiasis**).
- **Systemic mycoses:** Affect internal organs, often in immunocompromised individuals (e.g., **histoplasmosis**, **coccidioidomycosis**).

The most common superficial fungal infections are caused by **dermatophytes**, **yeasts** (e.g., **Candida**), or **molds** (e.g., **Aspergillus**).

2. Common Presenting Complaints and Symptoms:

a) Tinea Infections (Dermatophyte Infections):

- **Tinea pedis** (Athlete's foot):
 - **Itchy, scaly rash** between the toes, sometimes with maceration and fissuring.
 - **Erythema** and scaling may extend to the sole and sides of the foot.
- **Tinea corporis** (Ringworm):
 - **Circular or oval lesions** with raised borders and central clearing.
 - Commonly affects the **trunk, arms, or legs**.
- **Tinea cruris** (Jock itch):
 - **Itchy, red, and scaly rash** in the groin, inner thighs, or buttocks.
- **Tinea capitis** (Scalp ringworm):
 - **Scaly patches** with **hair loss** on the scalp, which may be inflamed or crusted.

b) Candidiasis:

- **Oral thrush:**
 - **White, creamy plaques** on the tongue, palate, or buccal mucosa that can be scraped off, leaving a **red base**.
 - Often associated with **immunosuppression, diabetes, or antibiotic use**.
- **Vaginal candidiasis:**
 - **Itching, burning, and cottage cheese-like discharge**.
 - Associated with **diabetes, pregnancy, and use of antibiotics**.
- **Intertrigo:**
 - **Erythematous, moist, and macerated skin** in skin folds (e.g., under the breasts, groin, or abdomen), commonly due to **Candida** infection.

c) Onychomycosis (Fungal Nail Infection):

- Thickened, discolored, and brittle nails, often with **yellow or white discoloration**.
- **Subungual debris** and **nail dystrophy**.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Most fungal infections can be diagnosed clinically based on characteristic signs like **erythema, scaling, and circular lesions** for tinea, or **white plaques** for candidiasis.

b) Microscopy and Culture:

1. **Skin scrapings for KOH preparation:**
 - A simple and quick test where **potassium hydroxide (KOH)** is used to dissolve keratin, allowing fungal elements (hyphae or spores) to be seen under a microscope.
2. **Fungal culture:**
 - Skin scrapings, nail clippings, or hair samples are cultured on **Sabouraud's agar** to identify the specific fungal species.

c) Wood's Lamp:

- **Wood's lamp examination** can help diagnose certain fungal infections (e.g., **tinea capitis**) by causing some fungi to fluoresce under ultraviolet light.

d) Nail Clippings:

- For suspected **onychomycosis**, **nail clippings** can be sent for **microscopy** and **culture** to confirm the diagnosis.

e) Blood Tests (for systemic infections):

- In suspected **systemic fungal infections** (e.g., **histoplasmosis**, **candidemia**), blood tests including **fungal serology**, **antigen testing**, and **blood cultures** may be performed.

4. Explanation of Investigations:

- **KOH preparation:** Dissolves the keratin and makes fungal hyphae or spores visible under the microscope.
- **Fungal culture:** Identifies the specific fungal pathogen, useful for tailoring treatment in resistant or recurrent cases.
- **Wood's lamp:** UV light causes certain fungi (e.g., **Microsporum**) to fluoresce, aiding in the diagnosis of **tinea capitis** or **pityriasis versicolor**.
- **Blood tests:** Detect fungal antigens or antibodies, important for diagnosing **systemic fungal infections**.

5. Diagnosis Criteria for Fungal Infections:

Fungal infections are diagnosed based on:

- **Clinical presentation:** Characteristic signs such as **scaling**, **circular lesions** (for tinea), or **white plaques** (for candidiasis).
- **Positive KOH test:** Visual confirmation of fungal hyphae or yeast under the microscope.
- **Fungal culture:** Growth of dermatophytes, yeast, or mold from skin scrapings, nail clippings, or hair samples.

6. First-Line Therapy According to Guidelines:

a) Topical Antifungals (for localized superficial infections):

1. **Clotrimazole** or **Miconazole** cream:
 - Applied **twice daily** for **2-4 weeks**.
 - Effective against **dermatophytes**, **yeasts**, and **molds**.
 - **Mechanism:** Inhibits **ergosterol synthesis**, disrupting the fungal cell membrane.
2. **Terbinafine** cream:
 - Applied **once daily** for **1-2 weeks**.
 - Particularly effective for **tinea** infections.
 - **Mechanism:** Inhibits **squalene epoxidase**, an enzyme crucial for fungal cell membrane formation.
3. **Nystatin** cream (for candidiasis):
 - Applied **2-3 times daily** for **1-2 weeks**.
 - Effective against **Candida** infections.
 - **Mechanism:** Binds to **ergosterol** in the fungal cell membrane, creating pores and causing cell death.

b) Oral Antifungals (for extensive or resistant infections):

1. **Oral Terbinafine:**
 - **250 mg once daily** for **6-12 weeks** for **onychomycosis** or **tinea capitis**.

- **Mechanism:** Inhibits **squalene epoxidase**, leading to fungal cell death.
- 2. **Oral Fluconazole:**
 - For **candidiasis** or **tinea corporis**: **150 mg once weekly** or **200 mg daily** for **2-4 weeks**.
 - **Mechanism:** Inhibits **ergosterol synthesis**, disrupting fungal cell membranes.
- 3. **Griseofulvin:**
 - For **tinea capitis** or **onychomycosis**: **500 mg to 1 g daily** for **4-8 weeks**.
 - **Mechanism:** Inhibits fungal cell mitosis.
- c) **Antifungal Shampoos (for tinea capitis or seborrheic dermatitis):**
 - **Ketoconazole shampoo:** Used **twice weekly** for **4 weeks**.
 - **Selenium sulfide:** Applied to the scalp to reduce fungal colonization.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Oral terbinafine:** Avoid in patients with **liver disease**, as it can cause **hepatotoxicity**.
- **Griseofulvin:** Contraindicated in **pregnant women** due to its potential **teratogenic effects**.

b) Second-Line Therapy:

1. **Itraconazole:**
 - Effective for **resistant tinea** and **onychomycosis**.
 - Dosage: **100-200 mg once daily** for **6-12 weeks**.
 - **Mechanism:** Inhibits **ergosterol synthesis**.
2. **Ciclopirox:**
 - Used as a **topical lacquer** for **onychomycosis**.
 - Applied to the affected nails daily.

8. Routine Monitoring and Follow-Up:

- **Response to treatment:** Improvement is expected within **2-4 weeks** for superficial infections and **3-6 months** for **onychomycosis**.
- **Liver function tests (LFTs):** Monitor if using **oral antifungals** (e.g., terbinafine, itraconazole) due to the risk of **hepatotoxicity**.
- **Recurrence:** Ensure patients follow up, as fungal infections often recur, especially in moist areas or immunocompromised individuals.

9. Complications:

1. **Chronic infections:**
 - Fungal infections such as **onychomycosis** and **tinea pedis** can become chronic, particularly in individuals with **diabetes**, **immunosuppression**, or poor hygiene.
 - Recurrence is common without appropriate treatment or prevention measures.
2. **Secondary bacterial infections:**
 - Areas of broken skin due to **scratching** or prolonged moisture can become secondarily infected with bacteria, leading to **cellulitis** or **impetigo**.
3. **Disseminated fungal infections:**
 - In **immunocompromised patients** (e.g., HIV, cancer, organ transplant), superficial fungal infections like **candidiasis** can spread to internal organs, resulting in systemic conditions such as **candidemia** or **invasive aspergillosis**.
4. **Hyperpigmentation and scarring:**

- Particularly with **tinea capitis** or severe **tinea corporis**, post-inflammatory **hyperpigmentation** and **scarring** can occur after the infection resolves, especially in darker skin types.

Summary of Key Points for Fungal Infections:

- **Fungal infections** can affect the skin, nails, hair, and mucous membranes, with common presentations including **tinea (ringworm)**, **onychomycosis**, and **candidiasis**.
- **Diagnosis** is often clinical but can be confirmed by **KOH microscopy**, **fungal culture**, or **Wood's lamp examination** for certain cases.
- **First-line treatments** include **topical antifungals** such as **clotrimazole** or **terbinafine** for localized infections, and **oral antifungals** (e.g., **fluconazole**, **terbinafine**) for more severe, extensive, or resistant cases.
- **Recurrence** and **chronicity** are common, especially in individuals with underlying conditions like diabetes or immunosuppression, and proper hygiene and preventive measures are important to reduce the risk.
- Complications include **secondary bacterial infections**, **chronic infections**, and in severe cases, **disseminated fungal infections** in immunocompromised patients.

100. Scabies

1. Detailed Definition of Scabies:

Scabies is a highly contagious skin infestation caused by the **Sarcoptes scabiei** mite. The female mite burrows into the epidermis to lay eggs, causing intense **itching** and a characteristic **rash**. Scabies can spread through **direct skin-to-skin contact** or, less commonly, by sharing contaminated clothing or bedding. The itching results from an **allergic reaction** to the mites, their eggs, and their feces.

2. Common Presenting Complaints and Symptoms:

- **Intense pruritus (itching):**
 - This is the hallmark symptom, often worse at **night**.
- **Papular rash:**
 - The rash consists of **small, erythematous papules** often in a **linear pattern** due to the burrows created by the mites.
- **Burrows:**
 - Thin, **serpiginous tracks** (burrows) are often seen in areas such as **interdigital spaces, wrists, elbows, umbilicus, axillae, and genital region**.
- **Crusted lesions** (Norwegian scabies):
 - In immunocompromised patients or the elderly, scabies can present as **thick, crusted plaques** (crusted or Norwegian scabies), which are heavily infested with mites and are highly contagious.
- **Excoriation:**
 - Due to persistent scratching, patients often develop **excoriations** and secondary bacterial infections like **impetigo**.
- **Delayed onset:**
 - Symptoms typically begin **4-6 weeks** after initial infestation in those who have never had scabies before. However, in previously infected individuals, symptoms may develop in just **1-4 days** after re-exposure.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Scabies is often diagnosed clinically based on the presence of **papular rash, burrows**, and the pattern of distribution (e.g., interdigital spaces, wrists, genital region).
- **History:** Ask about any contact with others who have itching or rash, as scabies is highly contagious.

b) Dermatoscopy:

- **Dermatoscopic examination** of the skin may reveal the **mite** or **burrows**, often described as a **dark triangular shape** (the head of the mite).

c) Skin Scrapings:

- **Skin scraping** from the affected area is performed and examined under a microscope for **mites, eggs**, or **fecal matter**.

d) Adhesive Tape Test:

- In some cases, **adhesive tape** can be applied to the lesion and then examined under a microscope for mites or eggs.

4. Explanation of Investigations:

- **Skin scraping:** A small scraping from a suspected burrow or lesion is examined under a microscope to confirm the presence of mites or their eggs.
- **Dermatoscopy:** Non-invasive and useful for visualizing **burrows** and identifying mites directly in the skin.
- **Adhesive tape test:** Useful in cases where skin scraping might not be practical; it picks up **eggs** or **mites** from the surface of the skin for microscopic examination.

5. Diagnosis Criteria for Scabies:

The diagnosis of scabies is based on:

- **Characteristic rash** with intense itching, especially in **skin folds, interdigital spaces, genital areas**, or **under the breasts**.
- **Burrows** seen on visual inspection or with dermatoscopy.
- **Microscopic identification** of mites, eggs, or feces from skin scrapings or tape test.
- **Contact history:** Recent exposure to family members or individuals with similar symptoms increases suspicion.

6. First-Line Therapy According to Guidelines:

a) Topical Scabicides:

1. **Permethrin 5% cream** (first-line treatment):
 - Applied to the **entire body** (from the neck down) and left on for **8-12 hours** before washing off. A second application is often recommended **1 week later** to kill newly hatched mites.
 - **Mechanism:** Permethrin disrupts the function of the mites' nerve cells, leading to paralysis and death.
2. **Benzyl benzoate 25%:**
 - Applied similarly to permethrin but may cause more skin irritation.
 - Applied **twice daily** for **2 days**.
3. **Sulfur 6-10% in petroleum jelly:**
 - Often used in **infants** or **pregnant women** where permethrin may be contraindicated.
 - Applied for **3 consecutive nights**.

b) Oral Treatment:

1. Ivermectin (oral):

- For patients who cannot tolerate topical treatments or have **crusted scabies**. It is particularly effective in **immunocompromised patients**.
- Dosage: **200 µg/kg** orally, usually repeated after **1-2 weeks**.
- **Mechanism**: Ivermectin paralyzes the mites by enhancing the inhibitory neurotransmitter **GABA**.

c) General Measures:

- **Treat all household members and close contacts** simultaneously, even if asymptomatic, to prevent reinfestation.
- **Clothing, bedding, and towels** should be washed in **hot water** and dried on a hot cycle. Items that cannot be washed should be sealed in plastic bags for **at least 72 hours** to kill mites.
- **Antihistamines** or **mild topical corticosteroids** can be used to manage post-treatment itching, which may persist for **2-4 weeks** (post-scabetic itch).

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Permethrin**: Avoid in patients with known **permethrin allergy**.
- **Ivermectin**: Not typically used in **pregnant women** or **children under 5 years** unless deemed necessary by a specialist.

b) Second-Line Therapy:

1. Lindane 1% lotion:

- Historically used but no longer recommended due to concerns about **neurotoxicity**, especially in children and pregnant women.

2. Crotamiton 10%:

- Applied **twice daily** for **5 days**, but less effective than **permethrin** or **ivermectin**.

8. Routine Monitoring and Follow-Up:

- **Resolution of rash**: Most patients experience improvement within **2-4 weeks** after treatment. However, **post-scabetic pruritus** (itching) can persist, even after successful treatment.
- **Check close contacts**: Ensure all household members and sexual partners have been treated to prevent **reinfection**.
- **Signs of secondary bacterial infection**: Monitor for signs of **impetigo** or **cellulitis**, which may occur due to scratching.

9. Complications:

1. Crusted (Norwegian) scabies:

- A severe form of scabies with **widespread crusting** and thickened plaques, often seen in **immunocompromised** individuals.
- Highly contagious and requires **oral ivermectin** and **topical permethrin** or **benzyl benzoate**.

2. Secondary bacterial infections:

- **Impetigo**, **cellulitis**, or **abscesses** can occur due to **scratching** and **skin breakdown**, particularly in children.

3. Post-scabetic itch:

- Persistent **itching** after eradication of the mites, possibly due to ongoing inflammation or a delayed hypersensitivity reaction.

Summary of Key Points for Scabies:

- **Scabies** is caused by the **Sarcoptes scabiei** mite, leading to intense **itching** and a **papular rash**, often worse at night.
- The characteristic **burrows** are usually found in the **interdigital spaces, wrists, genital region, and other skin folds**.
- **Diagnosis** is typically clinical but can be confirmed by **skin scrapings, dermatoscopy, or tape tests**.
- **First-line treatment** is **permethrin 5% cream**, applied to the entire body, with reapplication after **1 week**. **Ivermectin** can be used for severe cases, including **crusted scabies**.
- All **household members** and **close contacts** should be treated simultaneously to prevent reinfection, and **clothing and bedding** should be cleaned appropriately.
- Complications include **crusted scabies, secondary infections, and post-scabetic itch**.

101. Head Lice

1. Detailed Definition of Head Lice:

Head lice (*Pediculus humanus capitis*) are small, wingless parasitic insects that infest the scalp and feed on human blood. Head lice infestation, or **pediculosis capitis**, is most common in **children** and spreads through **direct head-to-head contact** or, less commonly, through sharing of personal items like **combs, hats, or pillows**. While head lice do not spread disease, they can cause **itching** and **discomfort** due to the allergic reaction to lice bites.

2. Common Presenting Complaints and Symptoms:

- **Intense scalp itching:**
 - This is the primary symptom, caused by an allergic reaction to lice saliva. The itching may worsen over time with repeated bites.
- **Visible lice or nits:**
 - **Lice** are small (2–3 mm), greyish-white insects that may be seen moving on the scalp or in the hair.
 - **Nits** (lice eggs) appear as tiny, oval, whitish-yellow specks attached to the hair shaft, typically within 1–2 cm of the scalp. Unlike dandruff, nits are firmly attached to the hair and do not flake off easily.
- **Excoriation and sores:**
 - Scratching the scalp can lead to **open sores** or **crusts**, which may become **infected** (e.g., impetigo).
- **Tickling or sensation of movement:**
 - Patients may report a **crawling sensation** on their scalp or neck.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is often made by examining the scalp for **live lice, nits, or excoriations**.
- **History:** Inquire about contact with other infested individuals (e.g., school classmates, family members).

b) Wet Combing (Detection Comb Method):

- **Wet combing** with a fine-toothed lice comb (0.2–0.3 mm spacing) is recommended to check for live lice. The hair is dampened and combed systematically, section by section.
- **Comb findings:** The presence of **live lice** confirms the diagnosis. **Nits** alone are not sufficient for diagnosis, as they may be from a previous infestation.

c) Magnification:

- Use of a **magnifying glass** or **dermatoscope** can help identify lice or nits, especially in cases of mild infestation.

4. Explanation of Investigations:

- **Wet combing:** This is the most reliable way to detect live lice and is preferred over visual inspection alone.
- **Magnification:** Helps differentiate lice or nits from other scalp debris like **dandruff**, **scabs**, or **hair casts**.

5. Diagnosis Criteria for Head Lice:

Head lice infestation is diagnosed based on:

- **Finding live lice:** The most definitive diagnosis is made when live lice are detected on the scalp or hair using the **wet combing method**.
- **Presence of nits:** Nits close to the scalp are suggestive of active infestation, but the presence of **nits alone** is not sufficient for diagnosis.

6. First-Line Therapy According to Guidelines:

a) Topical Pediculicides:

1. Permethrin 1% lotion or cream rinse:

- Applied to the **scalp** and **hair**, left on for **10 minutes**, and then rinsed off. A second treatment is often recommended after **7-10 days** to kill newly hatched lice.
- **Mechanism:** Permethrin paralyzes the lice by disrupting their nervous system.

2. Malathion 0.5% lotion:

- Applied to **dry hair**, left on for **8-12 hours**, and then rinsed out. Reapplication may be needed after **7 days**.
- **Mechanism:** Malathion is an **organophosphate** that inhibits **acetylcholinesterase**, causing respiratory paralysis in lice.

3. Dimeticone 4% lotion:

- Applied to dry hair, left on for **8 hours**, and then rinsed off. Reapplication after **7 days** is often required.
- **Mechanism:** Dimeticone is a silicone-based compound that **suffocates lice** by coating and immobilizing them.

4. Benzyl Alcohol 5% lotion:

- Applied to dry hair, left on for **10 minutes**, and then washed out. Repeat after **7 days**.
- **Mechanism:** Kills lice by **asphyxiation** without neurotoxic effects.

b) Wet Combing (Mechanical Removal):

- **Mechanical removal** using a fine-toothed lice comb on wet hair is an alternative or adjunct to chemical treatments. Hair should be combed every **3-4 days** for **2 weeks** to ensure all lice are removed.

c) General Measures:

- **Treat all household members:** Even asymptomatic individuals should be checked and treated to prevent reinfestation.
- **Laundering:** Clothing, bedding, and towels should be washed in **hot water** (>60°C) and dried on a hot cycle.
- **Vacuuming:** Floors, furniture, and car seats should be vacuumed to remove any fallen lice.
- **Avoid sharing** personal items like **combs, hats, or hair accessories**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Permethrin:** Avoid in patients with known **permethrin allergy**.
- **Malathion:** Avoid in children under **6 months** due to concerns about systemic absorption and potential toxicity.

b) Second-Line Therapy:

1. Spinosad 0.9% topical suspension:

- Applied to dry hair, left on for **10 minutes**, then rinsed off. Kills both **lice and eggs** and typically requires only one application.
- **Mechanism:** Disrupts the neural transmission in lice, causing paralysis and death.

2. Ivermectin 0.5% lotion:

- Applied to dry hair, left on for **10 minutes**, and then washed out. Does not require reapplication.
- **Mechanism:** Paralyzes lice by enhancing **GABA transmission** in the lice nervous system.

8. Routine Monitoring and Follow-Up:

- **Follow-up after treatment:** Re-examine the scalp after **7-10 days** to ensure no live lice remain.
- **Check close contacts:** Make sure all **household members** and individuals in close contact (e.g., classmates, playmates) are treated simultaneously to prevent reinfestation.
- **Lice persistence:** If live lice are still present after 2 treatments with the same agent, consider switching to a different **pediculicide** or using **wet combing** to remove remaining lice.

9. Complications:

1. Secondary bacterial infection:

- Persistent **scratching** may lead to **excoriations** and secondary bacterial infections, such as **impetigo** or **cellulitis**.

2. Treatment failure:

- Resistance to **permethrin** or **malathion** has been reported in some areas, leading to persistent infestations despite treatment. Switching to alternative therapies like **dimeticone** or **spinosad** may be necessary.

3. Social and psychological impact:

- Lice infestation may lead to **social stigma, embarrassment, and psychological distress**, particularly in children.

Summary of Key Points for Head Lice:

- **Head lice** are small parasitic insects that infest the **scalp** and cause intense **itching** due to an allergic reaction to their bites.
- Diagnosis is based on **visual inspection** or **wet combing** to detect live lice or nits.
- **First-line treatment** includes **topical permethrin 1%**, **malathion**, or **dimeticone**, with reapplication after **7 days** to kill newly hatched lice.
- **All close contacts** should be treated, and **clothing and bedding** should be washed or sealed to prevent reinfestation.
- **Mechanical removal** using **wet combing** is an effective alternative or adjunct to chemical treatments.
- Complications include **secondary bacterial infections** and **treatment resistance**, which may require alternative therapies.

102. Urticaria (Hives)

1. Detailed Definition of Urticaria:

Urticaria, commonly known as **hives**, is a skin condition characterized by the sudden appearance of **raised, itchy wheals** (hives) that can vary in size and shape. These hives may be surrounded by **erythema (redness)** and typically resolve within **24 hours** without leaving any marks. Urticaria can be classified into:

- **Acute urticaria**: Lasts for **less than 6 weeks**, often triggered by infections, allergens, or medications.
- **Chronic urticaria**: Lasts for **more than 6 weeks**, and may be either spontaneous (with no clear trigger) or inducible (e.g., physical triggers like pressure or cold).

Urticaria is often associated with **angioedema**, which involves deeper swelling of the skin, typically affecting the **face, lips, eyelids**, and **throat**.

2. Common Presenting Complaints and Symptoms:

- **Itchy wheals (hives)**:
 - These raised lesions are **erythematous, well-circumscribed**, and often **pale in the center**.
 - They may vary in size from small **papules** to large **plaques** and can occur anywhere on the body.
- **Sudden onset**:
 - Hives usually appear rapidly and can resolve within **hours**, though new lesions may appear in other areas.
- **Angioedema**:
 - Some patients may experience **deeper swelling** of the skin and mucous membranes, particularly on the **face, lips, eyelids**, or **throat**.
 - Angioedema can cause **pain** or **discomfort** and may impair breathing if the **airway** is involved.
- **Triggers**:
 - Common triggers for **acute urticaria** include **foods** (e.g., shellfish, nuts), **insect stings**, **medications** (e.g., NSAIDs, antibiotics), **infections**, and **stress**.
 - In **chronic urticaria**, the cause may be **idiopathic**, though physical triggers (e.g., pressure, heat, cold, exercise) are also common.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is often clinical, based on the characteristic appearance of **wheals** that are **transient** and **migratory** (i.e., they come and go in different areas of the body).
- **Patient history:** Ask about potential **triggers**, such as recent food intake, new medications, infections, or stress. History of **angioedema** or **anaphylaxis** is also important.

b) Blood Tests:

1. **Complete blood count (CBC):**
 - May be done to rule out infection or **eosinophilia** in cases of allergic urticaria.
2. **Serum tryptase:**
 - Elevated in **mast cell degranulation** and useful in ruling out **anaphylaxis** or **mastocytosis**.
3. **Thyroid function tests:**
 - Chronic urticaria can be associated with **autoimmune thyroid disease** (e.g., Hashimoto's thyroiditis).
4. **C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR):**
 - Done to assess for **inflammatory** or **infectious causes** in chronic urticaria.

c) Allergy Testing:

- **Skin prick testing** or **specific IgE blood testing** may be performed to identify possible **allergic triggers** in acute urticaria (e.g., foods, environmental allergens).

d) Physical Provocation Tests:

- For suspected **inducible urticaria**, such as **cold urticaria** or **dermatographism**, provocation tests (e.g., applying ice to the skin or stroking the skin) may be used to trigger hives.

4. Explanation of Investigations:

- **Complete blood count:** Helps rule out infection or allergy-related **eosinophilia**.
- **Serum tryptase:** Elevation indicates **mast cell activation**, seen in **anaphylaxis** or systemic mastocytosis.
- **Thyroid function tests:** Can help identify underlying **autoimmune disorders**, which are sometimes associated with chronic urticaria.
- **Allergy testing:** Useful in identifying **specific triggers** for acute urticaria, though not typically needed in chronic cases.
- **Physical provocation tests:** Used to identify **physical triggers** like **cold**, **pressure**, or **heat**, which can induce hives.

5. Diagnosis Criteria for Urticaria:

The diagnosis of urticaria is primarily **clinical** based on:

- The presence of **pruritic wheals** that typically resolve within **24 hours**.
- A **history of triggers** such as medications, infections, or allergens in acute cases.
- Recurrent hives lasting for more than **6 weeks** suggest **chronic urticaria**.

6. First-Line Therapy According to Guidelines:

a) Antihistamines (H1-antihistamines):

1. **Non-sedating H1-antihistamines:**
 - **Cetirizine**, **Loratadine**, or **Fexofenadine** are recommended as first-line treatment.

- Standard dosing is **once daily**, though in chronic urticaria, doses can be increased up to **four times** the standard dose.
 - **Mechanism:** Antihistamines block **H1 receptors**, preventing histamine from causing **itching** and **swelling**.
2. **Sedating antihistamines** (e.g., **Chlorpheniramine**, **Hydroxyzine**):
- May be used at night if **sleep disturbance** is significant due to itching.
 - **Mechanism:** Similar to non-sedating antihistamines but also have **sedative effects**.
- b) Short Course of Corticosteroids (for acute, severe cases):**
- **Prednisolone** 30-40 mg daily for **5 days** in severe, acute urticaria.
 - **Mechanism:** Reduces inflammation and immune response by suppressing the release of inflammatory mediators from mast cells.
- c) Avoidance of Triggers:**
- Identify and avoid **known triggers**, including **medications**, **foods**, or **environmental factors**.
- 7. Contraindications and Second-Line Therapy:**
- a) Contraindications to First-Line Therapy:**
- **Sedating antihistamines:** Avoid in individuals who need to **drive** or **operate machinery**, as these drugs can cause **drowsiness**.
- b) Second-Line Therapy:**
1. **H2 Antihistamines:**
 - **Ranitidine** or **Famotidine** can be used in combination with H1-antihistamines to provide additional symptom relief.
 - **Mechanism:** Blocks H2 receptors, reducing histamine release in the stomach and skin.
 2. **Montelukast** (Leukotriene receptor antagonist):
 - Can be added in **chronic urticaria** when antihistamines alone are not sufficient.
 - **Mechanism:** Blocks leukotrienes, which are inflammatory mediators involved in allergic reactions.
 3. **Omalizumab** (Anti-IgE therapy):
 - A monoclonal antibody that binds to IgE and prevents activation of mast cells.
 - Used in **chronic spontaneous urticaria** that is **refractory** to antihistamines.
 - **Dosage:** Given as **subcutaneous injections** every 2-4 weeks.
- 8. Routine Monitoring and Follow-Up:**
- **Symptom improvement:** Follow-up is needed to assess whether the patient responds to treatment, particularly if they are on high doses of **antihistamines** or are starting **second-line therapies**.
 - **Chronic urticaria:** Patients with chronic urticaria may need long-term treatment and **regular follow-ups** to monitor for response to antihistamines or other medications like **omalizumab**.
 - **Check for complications:** Monitor for signs of **angioedema** or **airway involvement**, which may require urgent intervention.
- 9. Complications:**
1. **Angioedema:**

- Urticaria is frequently associated with **angioedema**, particularly of the **face**, **lips**, and **throat**. If the **airway** becomes involved, it can lead to life-threatening **respiratory obstruction**.
- 2. **Anaphylaxis:**
 - Though rare, acute urticaria may be part of an **anaphylactic reaction**, characterized by **wheezing**, **difficulty breathing**, and **hypotension**. This is a medical emergency that requires immediate treatment with **epinephrine**.
- 3. **Impact on quality of life:**
 - Chronic urticaria, particularly if associated with **severe itching**, can lead to **poor sleep**, **anxiety**, and **depression**.

103. Stevens-Johnson Syndrome (SJS)

1. Detailed Definition of Stevens-Johnson Syndrome (SJS):

Stevens-Johnson Syndrome (SJS) is a severe, life-threatening hypersensitivity reaction primarily affecting the **skin** and **mucous membranes**. It is a form of **toxic epidermal necrolysis (TEN)**, where less than **10%** of the body surface area is involved in SJS, while in TEN, more than **30%** is affected. SJS is most often triggered by **medications**, infections, or in some cases, **unknown causes**.

It is characterized by widespread **epidermal necrosis**, leading to **detachment of the skin**, often starting with flu-like symptoms and progressing to **painful skin lesions**.

2. Common Presenting Complaints and Symptoms:

- **Prodromal symptoms** (often preceding the skin lesions by 1–3 days):
 - **Fever**, **malaise**, **sore throat**, **cough**, and **flu-like symptoms**.
 - These symptoms often mimic a viral illness.
- **Painful skin lesions:**
 - **Erythematous macules** or **flat atypical target-like lesions** that rapidly progress to **blisters** and **erosions**.
 - Lesions are **tender** and often start on the **face**, **trunk**, and **upper extremities**, and may spread to other areas of the body.
- **Mucosal involvement:**
 - **Painful erosions** of the **lips**, **oral cavity**, **conjunctiva**, **genitalia**, and **respiratory tract**.
 - **Severe conjunctivitis** can lead to **corneal scarring** and **blindness**.
 - **Oral mucosal erosions** may cause difficulty eating or swallowing.
- **Skin detachment:**
 - **Epidermal detachment** occurs in areas of necrotic skin, leading to **sloughing** and **denudation** of the skin.
 - **Nikolsky's sign**: Gentle rubbing of the skin causes it to **shear off** easily.
- **Systemic involvement:**
 - The patient may develop **multiorgan failure**, with the **kidneys**, **liver**, and **lungs** commonly affected.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is often clinical based on the appearance of **widespread blistering**, **erosions**, and **mucosal involvement**.

- **Patient history:** A thorough history of recent **medications** (especially **antibiotics**, **anticonvulsants**, and **NSAIDs**) and recent **infections** is crucial.

b) Skin Biopsy:

- A **skin biopsy** is the definitive test to confirm SJS and to differentiate it from other blistering disorders.
- **Histopathology** typically shows **full-thickness epidermal necrosis** with **minimal inflammation**.

c) Blood Tests:

1. **Complete blood count (CBC):**
 - May show **leukocytosis** (elevated white blood cell count) in cases of secondary infection or severe systemic involvement.
2. **Liver function tests (LFTs):**
 - Liver enzymes (AST, ALT) may be elevated if there is hepatic involvement.
3. **Renal function tests:**
 - **Blood urea nitrogen (BUN)** and **creatinine** levels may be elevated if the kidneys are affected.
4. **Electrolytes:**
 - Monitor for **electrolyte imbalances**, which can occur due to skin loss and dehydration.

d) Cultures:

- **Bacterial cultures** from erosions or blood may be required to rule out **secondary bacterial infections**.

4. Explanation of Investigations:

- **Skin biopsy:** The hallmark feature is **epidermal necrosis** with subepidermal cleft formation, and minimal inflammatory infiltrate, helping confirm the diagnosis of SJS.
- **Blood tests:** Monitor for evidence of **organ dysfunction**, **infection**, or **electrolyte imbalances** due to the extensive skin loss.
- **Cultures:** Secondary infections are common in patients with SJS due to compromised skin barriers, so cultures can help guide antibiotic therapy if infection is suspected.

5. Diagnosis Criteria for Stevens-Johnson Syndrome:

SJS is diagnosed based on:

- **Skin detachment** involving less than **10%** of the total body surface area (TBSA).
- **Mucosal involvement** (in at least two sites, e.g., oral, ocular, genital).
- **Recent medication use** (e.g., **sulfonamides**, **anticonvulsants**, **NSAIDs**) or history of infection.

In cases where more than **30%** of TBSA is affected, the condition is classified as **Toxic Epidermal Necrolysis (TEN)**.

6. First-Line Therapy According to Guidelines:

SJS is a **medical emergency** and requires hospitalization, often in an **intensive care unit (ICU)** or **burn unit**, where fluid and electrolyte balance, pain control, and wound care can be carefully managed.

a) Immediate Withdrawal of the Offending Drug:

- If a drug is suspected as the cause, it must be **discontinued immediately**. This can significantly improve the prognosis.

b) Supportive Care:

1. **Fluid and electrolyte management:**

- Patients with significant skin loss require careful management of **fluid** and **electrolytes** to prevent dehydration and shock.

2. **Wound care:**

- The affected skin is treated like **burns**, with **non-adherent dressings** and meticulous wound care to prevent infection.
- **Topical antibiotics** may be applied to prevent secondary infection.

3. **Pain management:**

- **Opioids** or other pain medications may be required for severe pain associated with widespread skin loss and mucosal involvement.

4. **Nutritional support:**

- **Nasogastric feeding** or **total parenteral nutrition (TPN)** may be needed if the patient has severe oral involvement and cannot eat.

c) Systemic Therapies:

1. **Corticosteroids:**

- **Systemic corticosteroids** (e.g., **methylprednisolone**) have been used, but their benefit is controversial and may increase the risk of infection.
- If used, they are typically given early in the disease process and tapered rapidly.

2. **Intravenous Immunoglobulin (IVIG):**

- IVIG is used in some cases to halt disease progression by neutralizing **autoantibodies** involved in epidermal damage.
- Dosage: Typically **2 g/kg** over 3-5 days.

3. **Cyclosporine:**

- An **immunosuppressive** agent used in some centers to reduce the immune-mediated damage in SJS.
- Dosage: **3-5 mg/kg/day**.

d) Antibiotic Therapy:

- Prophylactic antibiotics are **not recommended**, but antibiotics are indicated if there is evidence of a **secondary bacterial infection**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Prophylactic antibiotics** should not be used without evidence of infection, as they can increase the risk of antibiotic resistance and superinfection.

b) Second-Line Therapy:

1. **Plasmapheresis:**

- Used in severe or refractory cases to remove **circulating immune complexes** and **autoantibodies** involved in the disease process.

2. **TNF-alpha inhibitors:**

- In severe cases, **etanercept** or **infliximab** may be used to reduce inflammation and halt disease progression.

8. Routine Monitoring and Follow-Up:

- **Skin healing:** The extent of skin re-epithelialization should be monitored daily. Healing can take weeks, and residual skin pigmentation changes may occur.
- **Organ function:** Frequent monitoring of **renal**, **hepatic**, and **pulmonary** function is necessary, especially in severe cases.

- **Long-term sequelae:** Patients with significant mucosal involvement, particularly **ocular complications**, may require long-term follow-up with **ophthalmology** and **dermatology** to manage scarring and prevent further complications.

9. Complications:

1. **Secondary bacterial infection:**
 - The loss of the skin barrier increases the risk of bacterial infections, leading to **sepsis**, which is a leading cause of mortality in SJS.
2. **Multiorgan failure:**
 - SJS can affect multiple organs, including the **kidneys, lungs**, and **liver**, leading to **renal failure, pneumonitis**, and **hepatitis**.
3. **Long-term complications:**
 - **Ocular complications:** **Conjunctivitis, corneal scarring**, and **blindness**.
 - **Skin:** **Scarring, pigmentation changes**, and **nail dystrophy**.
 - **Oral:** **Chronic mucosal ulceration** and **dental complications**.

104. Toxic Epidermal Necrolysis (TEN)

1. Detailed Definition of Toxic Epidermal Necrolysis (TEN):

Toxic Epidermal Necrolysis (TEN) is a rare, life-threatening disorder characterized by widespread **epidermal detachment** and **mucosal involvement**. It represents the severe end of the spectrum of **drug-induced hypersensitivity reactions**, with **Stevens-Johnson Syndrome (SJS)** being the milder form. **TEN** involves **>30% of the total body surface area (TBSA)**, while **SJS** involves **<10%**, and **SJS/TEN overlap** occurs when **10-30%** of the TBSA is involved. **TEN** is most often triggered by **medications**, leading to massive **keratinocyte apoptosis** and **epidermal necrosis**. Mortality rates range from **30-50%**, primarily due to complications like **sepsis** and **multiorgan failure**.

2. Common Presenting Complaints and Symptoms:

- **Prodromal symptoms:**
 - Fever, malaise, cough, sore throat, and flu-like symptoms often precede the skin lesions by **1-3 days**.
- **Painful skin lesions:**
 - **Erythematous macules, vesicles**, and **bullae** that progress to **widespread epidermal detachment**. The skin lesions are **tender** and often start on the **face, trunk**, and **upper extremities**, and rapidly spread.
- **Mucosal involvement:**
 - Painful erosions of the **oral mucosa, conjunctiva, genitalia**, and **respiratory tract**.
 - **Oral erosions** may cause difficulty eating or swallowing, and **ocular involvement** can lead to severe conjunctivitis and **corneal scarring**.
- **Skin detachment:**
 - **Widespread epidermal necrosis** leads to **skin sloughing**, with large areas of **denudation** exposing raw dermis underneath.
 - **Nikolsky's sign:** Gentle pressure on the skin causes it to **peel off** easily, a hallmark of **TEN**.
- **Systemic involvement:**
 - Patients may develop **multiorgan failure**, including renal dysfunction, liver injury, and respiratory failure.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Diagnosis is often clinical, based on the **extent of skin detachment, erythema, and mucosal involvement**. Look for **Nikolsky's sign** and assess the **percentage of body surface area (BSA)** involved.

b) Skin Biopsy:

- A **skin biopsy** is crucial to confirm the diagnosis. The histopathology of TEN shows **full-thickness epidermal necrosis** with minimal inflammation, similar to **SJS**, but involving a larger surface area.

c) Blood Tests:

1. **Complete blood count (CBC):**
 - May show **leukocytosis** or **lymphopenia**.
2. **Liver function tests (LFTs):**
 - Assess for **elevated liver enzymes** due to liver involvement.
3. **Renal function tests:**
 - Monitor **serum creatinine** and **BUN** to evaluate for **acute kidney injury (AKI)** due to fluid loss or sepsis.
4. **Electrolytes:**
 - Check for **electrolyte imbalances** caused by massive fluid loss from the denuded skin.

d) Cultures:

- Perform **blood cultures** and wound swabs to check for **secondary bacterial infections**, as sepsis is a major concern.

4. Explanation of Investigations:

- **Skin biopsy:** Confirms the diagnosis by showing **full-thickness epidermal necrosis**, which is a hallmark of TEN.
- **Blood tests:** Help monitor for **organ involvement, infection, and fluid/electrolyte imbalances**.
- **Cultures:** Essential for detecting secondary infections, especially **sepsis**, which is the leading cause of death in TEN patients.

5. Diagnosis Criteria for Toxic Epidermal Necrolysis:

TEN is diagnosed based on:

- **Skin detachment** involving more than **30%** of the total body surface area (TBSA).
- **Mucosal involvement:** Typically affects two or more sites (e.g., **oral, ocular, genital**).
- A **history of medication use**, especially those known to trigger TEN (e.g., **sulfonamides, anticonvulsants, NSAIDs, allopurinol**).

6. First-Line Therapy According to Guidelines:

TEN is a **dermatologic emergency** requiring immediate **hospitalization** in an **intensive care unit (ICU)** or **burn unit** for multidisciplinary care, including **wound management, fluid resuscitation, and organ support**.

a) Immediate Withdrawal of the Offending Drug:

- The first and most critical step is to **immediately discontinue the offending drug**.

b) Supportive Care:

1. **Fluid and electrolyte management:**

- Fluid resuscitation is essential to prevent **hypovolemia** due to massive skin loss.
 - **Electrolyte imbalances** should be corrected through **intravenous fluids** and **electrolyte replacement**.
2. **Wound care:**
- The denuded skin should be treated like burns, using **non-adherent dressings** and ensuring a sterile environment to prevent infection.
 - **Topical antibiotics** (e.g., **silver sulfadiazine**) may be used to prevent secondary infection.
3. **Nutritional support:**
- **Enteral feeding** is preferred, but **parenteral nutrition** may be required if oral intake is not possible due to mucosal involvement.
- c) **Systemic Therapies:**
1. **Intravenous Immunoglobulin (IVIG):**
- IVIG is used in some cases to **neutralize autoantibodies** and halt the immune response.
 - Dosage: Typically **2 g/kg** over 3-5 days.
 - IVIG is believed to inhibit **Fas-mediated keratinocyte apoptosis**, thus reducing further skin necrosis.
2. **Corticosteroids:**
- The use of **systemic corticosteroids** in TEN remains controversial, as they may increase the risk of **infection**. However, some studies suggest that early, short-term use of **high-dose steroids** may be beneficial in halting disease progression.
3. **Cyclosporine:**
- **Cyclosporine** (an immunosuppressant) may reduce immune-mediated destruction of keratinocytes.
 - Dosage: **3-5 mg/kg/day**.
- d) **Antibiotic Therapy:**
- **Antibiotics** are not given prophylactically but are used if there is confirmed evidence of a **secondary bacterial infection**.
7. **Contraindications and Second-Line Therapy:**
- a) **Contraindications to First-Line Therapy:**
- **Prophylactic antibiotics** should not be used unless there is evidence of **secondary infection**, as they may promote the development of **antibiotic-resistant bacteria**.
- b) **Second-Line Therapy:**
1. **Plasmapheresis:**
- **Plasmapheresis** may be considered in severe cases to remove circulating **autoantibodies** and **immune complexes**.
2. **TNF-alpha inhibitors:**
- In some centers, **etanercept** or **infliximab** may be used to inhibit **tumour necrosis factor-alpha (TNF-α)**, a cytokine involved in the inflammatory response leading to epidermal necrosis.
8. **Routine Monitoring and Follow-Up:**
- **Monitoring for organ involvement:** Regularly monitor renal, hepatic, and respiratory function, as TEN can lead to **multiorgan failure**.

- **Skin healing:** Monitor the extent of skin re-epithelialization, which can take several weeks. Patients may be left with **permanent scarring** or **pigment changes**.
- **Ocular complications:** Long-term follow-up with **ophthalmology** is necessary to monitor for **corneal scarring** and **vision loss**.
- **Psychological support:** Due to the severe nature of TEN and its potential long-term consequences, patients may require **psychological counselling**.

9. Complications:

1. **Secondary bacterial infections:**
 - Due to the loss of the skin barrier, patients are at high risk of developing **cellulitis**, **sepsis**, and **pneumonia**, which are the leading causes of death in TEN.
2. **Multiorgan failure:**
 - TEN can cause **acute kidney injury**, **acute respiratory distress syndrome (ARDS)**, **liver failure**, and **myocarditis**.
3. **Long-term complications:**
 - **Ocular complications:** **Conjunctivitis**, **corneal ulceration**, and **blindness**.
 - **Skin:** **Scarring**, **hyperpigmentation**, and **nail dystrophy**.
 - **Mucosal involvement:** **Esophageal strictures**, **chronic oral ulcers**, **vaginal or urethral strictures**, and **genital scarring** are potential long-term complications due to severe mucosal damage.
 - **Pulmonary complications:** **Bronchial involvement** can lead to **pneumonitis**, **bronchiolitis obliterans**, or **acute respiratory distress syndrome (ARDS)**.
4. **Psychological impact:**
 - Due to the **severity** of the condition and potential for **disfigurement** and **long-term sequelae**, patients may experience significant **psychological distress**, **anxiety**, or **depression** and may benefit from **counselling** or **support groups**.

Summary of Key Points for Toxic Epidermal Necrolysis (TEN):

- **Toxic Epidermal Necrolysis (TEN)** is a severe, life-threatening condition characterized by **widespread epidermal necrosis** and **mucosal involvement**, typically triggered by **medications**.
- **Diagnosis** is based on **skin detachment involving >30% of the total body surface area (TBSA)**, **mucosal erosions**, and a history of drug exposure.
- **Immediate withdrawal of the offending drug** is crucial to halt disease progression.
- **Supportive care** is the mainstay of treatment, including **fluid resuscitation**, **wound care**, and **nutritional support**.
- **Systemic therapies** such as **IVIg** and **corticosteroids** may be used in select cases to halt immune-mediated damage.
- **Complications** include **secondary infections**, **multiorgan failure**, and **long-term scarring** or **mucosal strictures**.
- Long-term **follow-up** is needed to manage **ocular**, **pulmonary**, **mucosal**, and **psychological** complications.

105. Drug Eruptions

1. Detailed Definition of Drug Eruptions:

Drug eruptions, also known as **drug-induced skin reactions**, are adverse skin reactions caused by medications. They can range from mild **rashes** to severe life-threatening conditions

like **Stevens-Johnson Syndrome (SJS)** and **Toxic Epidermal Necrolysis (TEN)**. The skin reactions can occur anywhere from **hours** to **weeks** after taking a drug. These eruptions can present with a wide variety of morphologies, including **maculopapular rashes, urticaria, blisters**, and **systemic involvement**.

2. Common Presenting Complaints and Symptoms:

The type of skin reaction varies based on the drug and the individual's immune response. The most common types include:

a) Exanthematous (maculopapular) eruptions:

- **Widespread red macules and papules**, often starting on the trunk and spreading to the extremities.
- Typically appear **1-2 weeks** after starting the drug.
- Mild itching may be present.
- Commonly caused by **penicillins, sulfonamides, and antiepileptic drugs**.

b) Urticaria and angioedema:

- **Raised, red wheals** that are itchy and can appear suddenly.
- **Angioedema** involves deeper swelling, typically of the **face, lips, and eyelids**.
- May occur within **minutes to hours** of drug ingestion.
- Common triggers include **NSAIDs, ACE inhibitors, and antibiotics**.

c) Fixed drug eruption:

- A **well-defined, round or oval red or violaceous plaque** that reappears at the same site each time the drug is taken.
- Common locations include the **genitalia, hands, and lips**.
- Caused by **tetracyclines, NSAIDs, and sulfonamides**.

d) Erythema multiforme:

- **Target-like lesions** (red rings with a pale center) often seen on the **palms, soles, and mucosal surfaces**.
- Can be triggered by **antibiotics, antivirals, and anticonvulsants**.

e) Severe drug eruptions:

- **Stevens-Johnson Syndrome (SJS)** and **Toxic Epidermal Necrolysis (TEN)**: Characterized by **blisters, widespread skin detachment, and mucosal involvement**.
- **Drug rash with eosinophilia and systemic symptoms (DRESS)**: A severe reaction with **rash, fever, lymphadenopathy, and organ involvement** (e.g., liver, kidneys).

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection**: Diagnose based on the appearance of the rash, type of lesion (maculopapular, urticarial, bullous), and distribution.
- **History of drug use**: Ask about recent medications, especially new drugs started within the past **1-2 weeks**.

b) Blood Tests:

1. **Complete blood count (CBC)**:
 - Look for **eosinophilia** in cases of **DRESS** or **allergic drug reactions**.
2. **Liver function tests (LFTs)**:
 - Monitor for drug-induced liver injury in **DRESS** or other systemic drug reactions.
3. **Renal function tests**:
 - Assess for kidney involvement, especially in **DRESS** or **TEN**.

c) Skin Biopsy:

- A **skin biopsy** may be performed in uncertain cases or to confirm a severe drug eruption such as **SJS, TEN, or vasculitis**.

d) Patch Testing (in some cases):

- **Patch testing** may be done for **non-immediate** reactions like **allergic contact dermatitis**, but it is less useful for acute or severe drug reactions.

4. Explanation of Investigations:

- **CBC:** Elevated **eosinophils** suggest a **drug hypersensitivity** reaction.
- **Liver and renal function tests:** Monitor for evidence of **drug-induced organ damage**, particularly in severe drug reactions.
- **Skin biopsy:** Can help differentiate between drug eruptions and other skin conditions, showing **epidermal necrosis, eosinophilic infiltration, or interface dermatitis**, depending on the drug reaction type.

5. Diagnosis Criteria for Drug Eruptions:

Diagnosis is based on:

- **History of drug exposure**, particularly medications taken in the past **1-2 weeks**.
- **Clinical appearance** of the rash (e.g., **maculopapular, urticarial, bullous, or target lesions**).
- **Resolution upon drug discontinuation:** Most drug eruptions resolve within **1-2 weeks** after stopping the causative medication.
- In severe cases like **SJS** or **DRESS**, involvement of **mucosal surfaces** and **systemic symptoms** (fever, lymphadenopathy, organ involvement) is diagnostic.

6. First-Line Therapy According to Guidelines:

a) Immediate Discontinuation of the Suspected Drug:

- The first and most important step is to **stop the offending drug**. This can lead to the resolution of most mild drug eruptions within a week.

b) Symptomatic Treatment:

1. **Antihistamines** (for urticarial reactions):
 - **Cetirizine, Loratadine, or Fexofenadine** can be used to manage **itching** and **urticaria**.
 - **Mechanism:** Block **H1 receptors**, reducing the effects of histamine on the skin.
2. **Topical corticosteroids** (for mild drug rashes):
 - **Hydrocortisone or betamethasone** can be applied to localized rashes to reduce **inflammation** and **itching**.
 - **Mechanism:** Reduce local **inflammation** and immune response.

c) Systemic Corticosteroids (for severe reactions like DRESS):

- **Prednisolone: 0.5-1 mg/kg/day** may be used for severe drug eruptions such as **DRESS** or **erythema multiforme**.
 - **Mechanism:** Reduces systemic inflammation and suppresses the immune response.

d) Supportive Care for Severe Reactions (e.g., SJS/TEN):

- Hospitalization in an **ICU** or **burn unit** may be necessary for **TEN** or **SJS**.
- **Fluid and electrolyte management, wound care, and nutritional support** are critical.
- In some cases, **IV immunoglobulin (IVIG)** or **cyclosporine** may be used to halt disease progression in **SJS/TEN**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- Avoid **systemic corticosteroids** in patients with **mild maculopapular eruptions**, as these reactions typically resolve with drug discontinuation alone.

b) Second-Line Therapy:

1. **Immunosuppressants (e.g., cyclosporine):**
 - Used in **severe cases** like **SJS/TEN** to suppress the immune-mediated damage.
2. **Intravenous Immunoglobulin (IVIG):**
 - Used in some cases of **SJS/TEN** to neutralize **autoantibodies** that cause epidermal destruction.

8. Routine Monitoring and Follow-Up:

- **Resolution of rash:** Most drug eruptions resolve within **1-2 weeks** after the drug is discontinued. Monitor for signs of improvement or worsening.
- **Organ function:** In severe cases (e.g., **DRESS, TEN**), monitor **liver, renal, and pulmonary** function for evidence of **drug-induced damage**.
- **Rechallenge:** In cases where the drug must be reintroduced (e.g., chemotherapy), do so in a controlled setting, if appropriate, and consider using **desensitization protocols**.

9. Complications:

1. **Sepsis and multiorgan failure** (in severe reactions like **SJS/TEN**):
 - Due to widespread skin and mucosal damage, patients are at risk of secondary infections, leading to **sepsis** and **multiorgan failure**.
2. **Permanent skin damage:**
 - **Hyperpigmentation, scarring, and nail dystrophy** can result from severe drug eruptions like **TEN**.
3. **Chronic organ damage:**
 - In **DRESS**, drug-induced liver, kidney, or lung injury may result in long-term organ dysfunction.

Summary of Key Points for Drug Eruptions:

- **Drug eruptions** range from mild **maculopapular rashes** to severe, life-threatening reactions like **SJS** and **TEN**.
- The first step in management is **immediate discontinuation** of the suspected drug, followed by **supportive care** and **symptomatic treatment**.

106. Dermatomyositis

1. Detailed Definition of Dermatomyositis:

Dermatomyositis is a rare **idiopathic inflammatory myopathy** characterized by **muscle weakness** and distinctive **skin manifestations**. It is an autoimmune disorder that affects the **skeletal muscles**, leading to progressive weakness, and involves the **skin**, presenting with specific rashes. The condition can occur at any age but has bimodal peaks: **juvenile dermatomyositis** (children under 16) and **adult dermatomyositis**. It may be associated with underlying **malignancies** in adults (paraneoplastic syndrome).

2. Common Presenting Complaints and Symptoms:

a) Muscle Symptoms:

- **Proximal muscle weakness:**

- Progressive, symmetric weakness, especially of the **shoulders, hips, neck, and thighs**.
- Patients often report difficulty with tasks such as **standing up from a seated position, climbing stairs, or lifting objects**.
- **Myalgia** (muscle pain):
 - May be present, but weakness is the predominant symptom.
- **Dysphagia**:
 - Difficulty swallowing due to weakness of the oropharyngeal muscles.

b) Skin Symptoms:

- **Heliotrope rash**:
 - A **violet or dusky erythematous rash** on the **upper eyelids** with or without swelling.
- **Gottron's papules**:
 - Raised, violaceous **papules** found over the **knuckles, elbows, and knees**.
- **Shawl sign**:
 - **Erythematous rash** over the **upper back, shoulders, and neck** that may appear after sun exposure.
- **Mechanic's hands**:
 - Hyperkeratotic and **cracked skin** on the fingers, resembling the hands of a manual laborer.
- **Periungual erythema**:
 - **Redness** and capillary changes around the **nail folds**.

c) Systemic Symptoms:

- **Fatigue, fever, and weight loss** can accompany dermatomyositis, especially in cases associated with malignancies.

3. First-Line Investigations:

a) Clinical Examination:

- **Physical examination**:
 - Assess for **proximal muscle weakness** and skin findings such as **heliotrope rash, Gottron's papules, and the shawl sign**.

b) Blood Tests:

1. **Creatine kinase (CK)**:
 - Elevated CK levels indicate **muscle inflammation and damage**.
2. **Autoantibodies**:
 - **Anti-Mi-2**: Specific for dermatomyositis.
 - **Anti-Jo-1**: Common in patients with **interstitial lung disease** and **polymyositis**, less so in dermatomyositis.
3. **Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)**:
 - These markers can be elevated, reflecting the **inflammatory** nature of the disease.

c) Electromyography (EMG):

- Used to assess **muscle function**, showing abnormalities such as **irritability and muscle fiber inflammation**.

d) Muscle Biopsy:

- A **definitive diagnostic test** showing **perivascular inflammation** and **muscle fiber atrophy**.
- Biopsy reveals characteristic **perifascicular atrophy**, a hallmark of dermatomyositis.

e) Imaging:

- **MRI** of the muscles may show **oedema** and **inflammation**, useful for guiding muscle biopsy.

f) Cancer Screening:

- **CT scan, mammography, pelvic ultrasound, and colonoscopy** are recommended in adults to rule out **paraneoplastic dermatomyositis**, which is associated with underlying malignancies.

4. Explanation of Investigations:

- **Creatine kinase (CK):** Reflects **muscle damage**; levels are typically elevated during active disease.
- **Autoantibodies:** Help identify specific autoimmune processes involved in dermatomyositis and associated lung disease.
- **Muscle biopsy:** Provides **definitive evidence** of inflammation and muscle fiber necrosis.
- **Cancer screening:** Dermatomyositis is strongly associated with certain **malignancies** (ovarian, breast, lung, colorectal cancer), especially in older adults.

5. Diagnosis Criteria for Dermatomyositis:

Dermatomyositis is diagnosed based on:

1. **Proximal muscle weakness** (especially in shoulders, neck, and hips).
2. **Characteristic skin findings** (heliotrope rash, Gottron's papules, shawl sign).
3. **Elevated CK levels.**
4. **Abnormal EMG** findings (increased muscle irritability).
5. **Characteristic muscle biopsy** results (perivascular inflammation and perifascicular atrophy).

A combination of these criteria supports the diagnosis of dermatomyositis.

6. First-Line Therapy According to Guidelines:

a) Corticosteroids (First-Line):

- **Prednisolone:**
 - Dosage: **1-2 mg/kg/day**, followed by a **tapering dose** over several weeks once symptoms improve.
 - **Mechanism:** Corticosteroids suppress the immune system, reducing inflammation in the **muscles** and **skin**.

b) Immunosuppressive Agents:

1. **Methotrexate or Azathioprine:**
 - Used as **steroid-sparing agents** in patients with a poor response to corticosteroids or to reduce long-term steroid use.
 - **Mechanism:** Suppress **autoimmune activity** by inhibiting lymphocyte proliferation.
2. **Mycophenolate mofetil:**
 - Used particularly in patients with **lung involvement** (e.g., **interstitial lung disease**).
 - **Mechanism:** Inhibits **lymphocyte proliferation**, reducing inflammation in both muscles and lungs.

c) Intravenous Immunoglobulin (IVIG):

- May be used in **severe cases** or **refractory** dermatomyositis.

- **Mechanism:** IVIG modulates the immune system and reduces antibody-mediated damage.

d) Physical Therapy:

- **Physiotherapy** is essential to help patients regain **muscle strength** and prevent contractures due to **disuse**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Steroids** should be used cautiously in patients with **diabetes** or **osteoporosis** due to the risk of exacerbating these conditions.

b) Second-Line Therapy:

1. **Rituximab:**
 - A monoclonal antibody used for **refractory cases** of dermatomyositis.
 - **Mechanism:** Targets **CD20** on B cells, reducing their role in autoimmune responses.
2. **Cyclophosphamide:**
 - May be used in severe, refractory cases, particularly those involving **lung disease** or **vasculitis**.
 - **Mechanism:** Suppresses immune activity by **alkylating DNA**, leading to immune cell death.

8. Routine Monitoring and Follow-Up:

- **Muscle strength:** Regularly assess muscle function and strength to track response to treatment.
- **CK levels:** Monitor CK levels to gauge disease activity and response to therapy.
- **Drug monitoring:** In patients taking **immunosuppressants**, monitor for **side effects** like liver toxicity (with methotrexate) or bone marrow suppression (with azathioprine).
- **Screen for malignancies:** Continue routine cancer screening in patients with adult-onset dermatomyositis.

9. Complications:

1. **Malignancy:**
 - Dermatomyositis is associated with an increased risk of **malignancies**, particularly **ovarian, breast, lung, and colorectal cancers**.
2. **Pulmonary complications:**
 - Patients may develop **interstitial lung disease**, which can lead to progressive **dyspnea** and **pulmonary fibrosis**.
3. **Dysphagia:**
 - Oropharyngeal muscle involvement can lead to **difficulty swallowing** and **aspiration pneumonia**.
4. **Calcinosis:**
 - **Calcium deposits** in the skin and muscles, more common in **juvenile dermatomyositis**.
5. **Chronic disability:**
 - If untreated or inadequately treated, dermatomyositis can lead to **muscle wasting** and **permanent weakness**.

Summary of Key Points for Dermatomyositis:

- **Dermatomyositis** is an autoimmune disorder characterized by **proximal muscle weakness** and distinctive **skin rashes**.
- Diagnosis is based on a combination of **clinical findings, elevated CK, abnormal EMG, and muscle biopsy**.
- **First-line treatment** includes **corticosteroids** and **immunosuppressive agents** such as **methotrexate** or **azathioprine**.
- Regular **cancer screening** is necessary due to the strong association with **

107. Neurofibromatosis

1. Detailed Definition of Neurofibromatosis:

Neurofibromatosis (NF) is a genetic disorder that causes the development of **tumours** along nerves in the skin, brain, and other parts of the body. The condition has two main types:

- **Neurofibromatosis type 1 (NF1)** (also known as von Recklinghausen disease): This is the more common type, occurring in approximately **1 in 3,000 births**, and characterized by skin and bone changes as well as the development of tumours along nerves.
- **Neurofibromatosis type 2 (NF2)**: Less common, occurring in approximately **1 in 25,000 births**, and characterized by the development of **vestibular schwannomas** (tumours affecting the auditory nerves) and other tumours of the **central nervous system (CNS)**.

2. Common Presenting Complaints and Symptoms:

Neurofibromatosis Type 1 (NF1):

- **Café-au-lait spots:**
 - Flat, light brown patches on the skin. Having **six or more** café-au-lait spots larger than **5 mm** in diameter (in pre-pubertal children) or **15 mm** (in post-pubertal individuals) is suggestive of NF1.
- **Neurofibromas:**
 - **Benign nerve tumours** that develop on or under the skin, often presenting as soft, fleshy nodules. These tumours may also form along nerves deeper in the body.
- **Lisch nodules:**
 - **Pigmented hamartomas** found in the **iris** of the eye, which do not affect vision but are highly specific for NF1.
- **Axillary or inguinal freckling:**
 - Freckling in areas not typically exposed to sunlight (e.g., under the arms or in the groin) is another hallmark of NF1.
- **Plexiform neurofibromas:**
 - Large, often **disfiguring nerve sheath tumours** that can cause pain, functional impairment, and cosmetic issues.
- **Bone deformities:**
 - Common skeletal problems include **scoliosis** (curvature of the spine) and **pseudoarthrosis** (false joint formation, often in the tibia).
- **Learning difficulties:**
 - Approximately **50%** of individuals with NF1 have mild to moderate learning disabilities or attention deficit disorders.
- **Seizures:**
 - Seizures are more common in people with **NF1** than in the general population.

Neurofibromatosis Type 2 (NF2):

- **Hearing loss:**

- Caused by **vestibular schwannomas** (tumours on the auditory nerve), leading to **gradual hearing loss**, **tinnitus** (ringing in the ears), and **balance issues**.
- **Meningiomas and ependymomas:**
 - **Benign brain or spinal cord tumours**, causing symptoms such as **headaches**, **visual disturbances**, and **motor deficits**.
- **Cataracts:**
 - Early-onset **cataracts** may develop, often in the teenage years.
- **Peripheral neuropathy:**
 - Loss of sensation, weakness, or other neurological symptoms due to tumour involvement of peripheral nerves.

3. First-Line Investigations:

a) Clinical Examination:

- **Skin examination:** Look for the characteristic **café-au-lait spots**, **neurofibromas**, and **freckling**.
- **Ophthalmological exam:** To detect **Lisch nodules** in NF1 and **cataracts** or retinal abnormalities in NF2.
- **Hearing assessment:** For hearing loss in patients with suspected **vestibular schwannomas** (NF2).

b) Imaging:

1. **MRI or CT scans:**
 - **MRI of the brain and spine** is crucial for detecting **vestibular schwannomas** (NF2), **optic gliomas**, and other tumours (both NF1 and NF2).
 - **CT** may be used to assess bone abnormalities like **scoliosis** or **pseudoarthrosis**.
2. **X-rays:**
 - Used to detect **bone deformities** such as **scoliosis** or other skeletal issues related to NF1.

c) Genetic Testing:

- **NF1 gene** testing is available for individuals with suspected **NF1** and can confirm the diagnosis.
- **NF2 gene** testing is used for those with **NF2**, especially if there is a **family history** or early onset of **vestibular schwannomas**.

d) Audiology:

- **Hearing tests:** Essential in patients with **NF2** to evaluate hearing loss or vestibular dysfunction related to **schwannomas**.

4. Explanation of Investigations:

- **MRI/CT:** These imaging studies are critical for identifying **tumours** of the brain, spinal cord, or peripheral nerves.
- **Genetic testing:** Confirms the diagnosis by identifying mutations in the **NF1** or **NF2** genes.
- **Ophthalmological and audiology assessments:** Help detect complications such as **cataracts**, **optic gliomas**, and **hearing loss**.

5. Diagnosis Criteria for Neurofibromatosis:

Neurofibromatosis Type 1 (NF1) Diagnosis Criteria:

Requires **two or more** of the following:

1. **Six or more café-au-lait spots** larger than 5 mm in pre-pubertal individuals or 15 mm in post-pubertal individuals.
2. **Two or more neurofibromas** of any type or one **plexiform neurofibroma**.
3. **Freckling** in the axillary or inguinal region.
4. **Optic glioma** (tumour of the optic nerve).
5. **Two or more Lisch nodules** (iris hamartomas).
6. A distinctive **bone lesion**, such as **sphenoid dysplasia** or pseudoarthrosis.
7. A **first-degree relative** (parent, sibling, or child) with NF1 based on the above criteria.

Neurofibromatosis Type 2 (NF2) Diagnosis Criteria:

Requires:

1. **Bilateral vestibular schwannomas** (on both sides) or
2. **Unilateral vestibular schwannoma** and any of the following:
 - **Meningioma**
 - **Schwannoma**
 - **Glioma**
 - **Juvenile posterior subcapsular cataract** or
 - A **first-degree relative** with NF2.

6. First-Line Therapy According to Guidelines:

There is **no cure** for neurofibromatosis, so treatment is mainly aimed at **managing symptoms** and **complications**.

a) Surgical Management:

1. **Surgical removal of neurofibromas:**
 - Indicated for **disfiguring** or **painful neurofibromas** or **plexiform neurofibromas** causing functional impairment.
2. **Surgery for vestibular schwannomas (NF2):**
 - **Microsurgical resection** or **stereotactic radiosurgery** (e.g., **Gamma Knife**) is used for vestibular schwannomas causing significant hearing loss or imbalance.
3. **Spinal surgery:**
 - May be necessary to correct **scoliosis** or other significant bone deformities.

b) Symptomatic Management:

1. **Physical and occupational therapy:**
 - Helps patients cope with **muscle weakness**, **scoliosis**, and other motor issues.
2. **Pain management:**
 - Neurofibromas and other tumours can cause significant pain, requiring **analgesics** or even surgical intervention.
3. **Hearing aids or cochlear implants:**
 - In cases of **hearing loss** caused by vestibular schwannomas, these devices may be used to restore **hearing**.

c) Drug Therapy:

1. **MEK inhibitors** (e.g., **selumetinib**):
 - Recently approved for use in children with **inoperable plexiform neurofibromas**. These inhibitors target the **RAS/MAPK pathway**, which is hyperactive in NF1 tumours.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Surgery:

- Surgery for **vestibular schwannomas** may not be appropriate in all cases, especially if the tumours are **small** or not causing significant symptoms. Observation and **regular MRI follow-up** may be recommended.

b) Second-Line Therapy:

- **Radiotherapy** (e.g., stereotactic radiosurgery) may be used for **vestibular schwannomas** in patients who are not surgical candidates.

8. Routine Monitoring and Follow-Up:

- **Annual physical exams** to check for new or growing **neurofibromas** and other complications.
- **MRI scans** to monitor for the development or progression of **brain, spinal cord, or peripheral nerve tumours**.
- **Regular audiometry and ophthalmological assessments** to evaluate for **hearing loss** and **eye complications**.
- **Cancer screening:** Patients with **NF1** may require regular monitoring for **malignant peripheral nerve sheath tumours (MPNST)**, which occur in approximately **10%** of individuals with NF1. Routine imaging (MRI or PET scans) can be used for early detection, especially if there is rapid growth of a **plexiform neurofibroma**.
- **Endocrinological follow-up:** Children with **NF1** should be monitored for **precocious puberty, growth abnormalities, and hypertension**, which can be caused by renal artery stenosis or pheochromocytoma.
- **Regular cognitive and developmental assessments:** Since **learning disabilities** are common in individuals with **NF1**, children should have early developmental and cognitive evaluations, with appropriate **educational interventions** when necessary.
- **Vision screening:** Regular ophthalmology check-ups to monitor for **optic gliomas** and other ocular complications in both NF1 and NF2 patients.
- **Hearing assessments:** For patients with **NF2**, regular audiological evaluations are essential to detect early hearing loss due to **vestibular schwannomas**.

9. Complications:

1. **Malignant transformation:**
 - **Malignant peripheral nerve sheath tumours (MPNSTs)** can develop from plexiform neurofibromas in **NF1**. These tumours are aggressive and require prompt surgical resection and/or **chemotherapy**.
2. **Hearing loss and balance issues:**
 - Patients with **NF2** are at high risk of developing **profound hearing loss** and **balance problems** due to vestibular schwannomas. These may lead to significant disability.
3. **Scoliosis and other orthopedic complications:**
 - **Scoliosis** in **NF1** can progress and require **spinal surgery** to prevent deformity or neurological impairment.
4. **Cognitive impairment:**
 - **Learning disabilities, attention deficit disorders, and intellectual disabilities** are common in **NF1**. Early intervention with educational support and behavioral therapy is crucial.
5. **Ocular complications:**

- **Cataracts, retinal hamartomas, and optic pathway gliomas** can impair vision in both **NF1** and **NF2**. If optic gliomas progress, they may lead to **vision loss** and require treatment with **chemotherapy** or **radiation**.

Summary of Key Points for Neurofibromatosis:

- **Neurofibromatosis** is a genetic disorder characterized by the development of **nerve tumours** and distinct **skin changes**, with **NF1** involving **neurofibromas** and **café-au-lait spots**, and **NF2** involving **vestibular schwannomas** and **hearing loss**.
- Diagnosis is based on **clinical criteria**, **genetic testing**, and **imaging** to confirm the presence of tumours and assess their extent.
- Treatment focuses on **managing symptoms** and preventing complications, with **surgical removal** of tumours, **physical therapy**, and, in some cases, the use of **targeted therapies** like **MEK inhibitors**.
- **Routine follow-up** is essential to monitor for tumour growth, hearing loss, and other complications, as well as to manage any **cognitive** or **developmental issues**.

108. Tuberous Sclerosis

1. Detailed Definition of Tuberous Sclerosis:

Tuberous Sclerosis Complex (TSC) is a genetic disorder characterized by the development of **benign tumours** in multiple organs, including the **brain, skin, kidneys, lungs, and heart**. TSC is caused by mutations in the **TSC1** or **TSC2** genes, which regulate **cell growth** and division. The dysfunction in these genes leads to **overgrowth of cells**, resulting in benign tumours (hamartomas) in various organs. The clinical manifestations of TSC vary widely, with some patients having mild symptoms, while others experience severe complications like **seizures** or **intellectual disability**.

2. Common Presenting Complaints and Symptoms:

a) Neurological Symptoms:

- **Seizures:**
 - **Seizures** are the most common presenting symptom in **TSC**, typically starting in early childhood. **Infantile spasms** are a specific type of seizure seen in infants with TSC.
 - **Epilepsy** is often difficult to control in these patients.
- **Developmental delays:**
 - Many children with TSC have **delayed milestones**, and a significant percentage have **intellectual disabilities**.
- **Autism spectrum disorder (ASD):**
 - **Autism** or **autistic behaviors** are common in children with TSC, affecting communication and social interaction.
- **Behavioral issues:**
 - **Aggressiveness, hyperactivity, and sleep disturbances** are frequently reported.

b) Skin Symptoms:

- **Facial angiofibromas:**
 - These are **reddish, raised papules** that typically appear on the **nose** and **cheeks** (butterfly distribution) during childhood.
- **Hypomelanotic macules** ("ash leaf spots"):

- These are **white patches** on the skin, often the first sign of TSC, especially in infants. They can be seen using a **Wood's lamp**.
 - **Shagreen patches:**
 - **Thickened, rough patches** of skin that usually appear on the **lower back** and resemble **orange-peel**.
 - **Ungual fibromas:**
 - Fibrous growths that occur around the **nails**, particularly the toenails.
- c) Renal Symptoms:**
- **Renal angiomyolipomas:**
 - These are **benign tumours** of the kidney made up of blood vessels, muscle, and fat. They can cause **pain, haematuria**, and, in severe cases, **renal failure**.
- d) Cardiac Symptoms:**
- **Cardiac rhabdomyomas:**
 - Benign **heart tumours** often found in infants, which may lead to **arrhythmias** or **heart failure**, but tend to regress with age.
- e) Pulmonary Symptoms:**
- **Lymphangioleiomyomatosis (LAM):**
 - A lung condition seen primarily in **women** with TSC, leading to **progressive breathlessness** and, in severe cases, **respiratory failure**.
- f) Ophthalmological Symptoms:**
- **Retinal hamartomas:**
 - Benign tumours in the eye, which are often asymptomatic but may cause **vision impairment** if large.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Assess for **facial angiofibromas**, **ash leaf spots**, **Shagreen patches**, and **ungual fibromas**.
- **Neurological exam:** Evaluate for **seizures**, **developmental delay**, and signs of **intellectual disability**.

b) Imaging:

1. **Brain MRI:**
 - **Cortical tubers**, **subependymal nodules**, or **subependymal giant cell astrocytomas (SEGA)** can be identified. These brain lesions are key findings in TSC and may cause **seizures** or **hydrocephalus**.
2. **Renal ultrasound or MRI:**
 - To detect **renal angiomyolipomas** or **renal cysts**, which are common in TSC.
3. **Cardiac echocardiography:**
 - Used to identify **cardiac rhabdomyomas**, especially in infants.
4. **Chest CT:**
 - May be done in adult women to assess for **lymphangioleiomyomatosis (LAM)** in the lungs.

c) Genetic Testing:

- **TSC1** and **TSC2** **gene** testing can confirm the diagnosis. Mutations in these genes are responsible for **dysregulated cell growth** leading to TSC.

d) Electroencephalogram (EEG):

- Used to evaluate the **type and severity of seizures**, especially in children with TSC and **infantile spasms**.

e) Ophthalmology Examination:

- Regular eye exams are required to detect **retinal hamartomas** or other ocular findings.

4. Explanation of Investigations:

- **Brain MRI:** Detects **cortical tubers** and **subependymal nodules** that can lead to **seizures** or **neurological deficits**.
- **Genetic testing:** Confirms the presence of mutations in the **TSC1** or **TSC2 genes**, providing definitive diagnosis.
- **EEG:** Helps identify and monitor **epileptic activity** in children with seizures.
- **Renal ultrasound/MRI:** Used to monitor for **angiomyolipomas**, which can affect kidney function.

5. Diagnosis Criteria for Tuberous Sclerosis:

The **clinical diagnostic criteria** for Tuberous Sclerosis Complex (TSC) include **major** and **minor features**. Diagnosis is confirmed by:

- **Two major features**, or
- **One major and two or more minor features**.

Major features:

1. **Facial angiofibromas** or **forehead plaque**.
2. **Hypomelanotic macules** (3 or more).
3. **Shagreen patch**.
4. **Renal angiomyolipoma**.
5. **Cardiac rhabdomyoma**.
6. **Cortical dysplasias** (cortical tubers).
7. **Subependymal nodules** or **SEGA**.
8. **Multiple retinal hamartomas**.
9. **Lymphangioleiomyomatosis (LAM)**.

Minor features:

1. **Confetti skin lesions**.
2. **Dental enamel pits** (3 or more).
3. **Intraoral fibromas**.
4. **Bone cysts**.
5. **Nonrenal hamartomas**.
6. **Multiple renal cysts**.

6. First-Line Therapy According to Guidelines:

a) Antiepileptic Drugs (AEDs):

- **Antiepileptic drugs (AEDs)** such as **vigabatrin**, **levetiracetam**, or **topiramate** are used to manage **seizures** in TSC patients.
 - **Vigabatrin** is especially effective in treating **infantile spasms**.

b) mTOR Inhibitors:

1. **Everolimus:**
 - **Mechanism:** Targets the **mTOR pathway**, which is dysregulated in TSC, reducing tumour growth.
 - Used to shrink **SEGA**, **renal angiomyolipomas**, and control **seizures** that are refractory to conventional treatment.
2. **Sirolimus:**
 - Another **mTOR inhibitor** used to manage **renal** and **pulmonary** complications.

c) Surgical Management:

1. Resection of SEGA:

- Surgery is indicated for large **subependymal giant cell astrocytomas (SEGA)** causing **hydrocephalus**.

2. Surgical removal of renal angiomyolipomas:

- Large angiomyolipomas that cause **pain, bleeding**, or impair **kidney function** may require surgical removal.

d) Behavioral Therapy:

- **Cognitive behavioral therapy (CBT)** and **developmental support** for patients with **intellectual disabilities, autism**, or behavioral problems.

e) Cardiac Monitoring:

- **Regular echocardiograms** are important to monitor for the regression of **cardiac rhabdomyomas**, which may interfere with heart function in infancy.

7. Contraindications and Second-Line Therapy:

a) Contraindications:

- Careful consideration should be given to **mTOR inhibitors** in patients with **immunosuppressive conditions** as they can impair **immune function**.

b) Second-Line Therapy:

- **Ketogenic diet:** May be considered for patients with **refractory epilepsy** who do not respond to conventional AEDs.
- **Vagus nerve stimulation (VNS):** Can be used as an adjunctive therapy in **refractory epilepsy**.

8. Routine Monitoring and Follow-Up:

- **MRI scans:** Regular imaging to monitor the size of **SEGA, cortical tubers**, and renal angiomyomas is crucial to prevent complications such as **hydrocephalus** or **renal failure**.
- **EEG monitoring:** For patients with **epilepsy**, especially those with **refractory seizures**, to adjust antiepileptic drug therapy.
- **Renal function tests:** Regular monitoring of kidney function in patients with **renal angiomyolipomas** to detect any deterioration in function or evidence of bleeding.
- **Cardiac echocardiography:** In infants, regular echocardiograms to monitor **cardiac rhabdomyomas**, which usually regress with age.
- **Ophthalmological examinations:** Routine eye exams to monitor for the development of **retinal hamartomas** or other vision-related complications.
- **Developmental and behavioral assessments:** Regular assessments are required for children with **autism, intellectual disability**, or other **developmental delays** to ensure they receive appropriate support and therapy.
- **Pulmonary function tests:** Particularly in adult women, to monitor for **lymphangioleiomyomatosis (LAM)**, which can affect lung function.

9. Complications:

1. Epilepsy:

- Many patients with **TSC** have **intractable epilepsy**, which can significantly impact quality of life. **SEGA** or cortical tubers may be contributing to **seizures** and require **mTOR inhibitors** or **surgical intervention**.

2. Renal failure:

- **Renal angiomyolipomas** can grow large and cause **bleeding** or **renal failure** if left untreated. **mTOR inhibitors** are often used to shrink these tumours and preserve renal function.
- 3. **Cognitive and developmental delay:**
 - **Intellectual disabilities, learning difficulties,** and **autism** are common in TSC, requiring **special education, therapy,** and **support.**
- 4. **Hydrocephalus:**
 - **Subependymal giant cell astrocytomas (SEGA)** can obstruct the ventricles, leading to **hydrocephalus.** Early detection through imaging and, if necessary, **surgical removal** is essential.
- 5. **Respiratory failure:**
 - In women, **lymphangioleiomyomatosis (LAM)** can progress to **severe lung disease,** leading to **respiratory failure.**
- 6. **Cardiac arrhythmias:**
 - **Cardiac rhabdomyomas** may cause **arrhythmias** in infants, though these tumours usually regress with age.

Summary of Key Points for Tuberous Sclerosis (TSC):

- **Tuberous sclerosis** is a genetic disorder that causes the growth of **benign tumours** in multiple organs, particularly the **brain, kidneys, heart, skin,** and **lungs.**
- **Diagnosis** is based on **clinical criteria** and **genetic testing** for mutations in the **TSC1** or **TSC2** genes.
- **Management** focuses on controlling **seizures,** managing **tumours,** and monitoring for complications like **renal failure, hydrocephalus,** and **pulmonary issues.**
- **mTOR inhibitors,** such as **everolimus** and **sirolimus,** are key treatments to reduce the size of **tumours** in various organs.
- **Routine follow-up** and **monitoring** for complications are essential to manage this chronic condition and prevent severe outcomes.

109. Cutaneous Manifestations of Malignancy

1. Detailed Definition of Cutaneous Manifestations of Malignancy:

Cutaneous manifestations of malignancy are **skin changes** that can either be directly related to a **malignant tumour** (such as **cutaneous metastases**) or are **paraneoplastic syndromes** associated with an internal malignancy. These skin signs may precede the diagnosis of cancer, coincide with the disease, or present during cancer progression. Some cutaneous manifestations are specific to certain cancers, while others may indicate a general malignancy.

2. Common Presenting Complaints and Symptoms:

a) Direct Cutaneous Involvement by Malignancy:

1. **Cutaneous metastases:**
 - Firm, **painless** nodules or plaques that can be **skin-coloured, pink,** or **purple.**
 - They may ulcerate and are often seen in **breast cancer, lung cancer, melanoma,** and **colorectal cancer.**
2. **Leukemia cutis:**
 - **Red or purple nodules or plaques,** typically involving the skin of the **trunk, arms,** or **legs,** seen in patients with **leukemia.**
3. **Lymphoma (cutaneous T-cell lymphoma):**
 - Presents with **erythematous patches, plaques,** or **nodules.**

- **Mycosis fungoides** and **Sézary syndrome** are common examples of cutaneous lymphomas.

b) Paraneoplastic Syndromes (skin changes associated with internal malignancies):

- 1. Acanthosis nigricans:**
 - **Velvety, hyperpigmented plaques** typically found in the **axilla, groin, and neck**.
 - Can be associated with **gastrointestinal cancers**, particularly **gastric adenocarcinoma**.
- 2. Dermatomyositis:**
 - Characterized by **heliotrope rash** (purple rash on the eyelids) and **Gotttron's papules** (on the knuckles).
 - Often associated with **ovarian, lung, gastric, and colorectal cancers** in adults.
- 3. Erythema gyratum repens:**
 - **Concentric, red bands** on the skin that resemble the rings of a tree.
 - Strongly associated with **lung cancer**, but can also occur with **breast and esophageal cancers**.
- 4. Necrolytic migratory erythema:**
 - **Erythematous patches** with central clearing, primarily affecting the **face, lower abdomen, and groin**.
 - Associated with **glucagonoma**, a rare pancreatic tumour.
- 5. Sweet's syndrome (acute febrile neutrophilic dermatosis):**
 - **Painful, red or purple plaques** accompanied by **fever**.
 - Often linked with **hematologic malignancies** such as **acute myeloid leukemia**.
- 6. Leser-Trélat sign:**
 - Sudden onset of multiple **seborrheic keratoses**.
 - Suggests underlying **gastric adenocarcinoma** or other **gastrointestinal and lung cancers**.
- 7. Hypertrichosis lanuginosa acquisita:**
 - **Excessive growth of fine, downy hair**, typically on the **face and ears**.
 - Linked to **lung cancer, colon cancer, and breast cancer**.
- 8. Bazex syndrome (paraneoplastic acrokeratosis):**
 - **Psoriasiform plaques** on the **hands, feet, and ears**.
 - Associated with **upper aerodigestive tract malignancies** (e.g., esophageal or laryngeal cancer).
- 9. Erythroderma:**
 - Diffuse, **widespread redness** of the skin, which can be associated with **lymphomas**, such as **Sézary syndrome** (a form of cutaneous T-cell lymphoma).

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Look for characteristic signs such as **skin nodules, plaques, hyperpigmented patches, and rashes**.
- **Palpation:** Assess the **firmness** and **mobility** of skin nodules, which may suggest metastases.

b) Biopsy:

- 1. Skin biopsy:**
 - A **punch biopsy** or **excisional biopsy** is essential to confirm the diagnosis of **cutaneous metastases, lymphomas, or paraneoplastic dermatoses**.
- 2. Histopathological examination:**

- Helps distinguish **malignant cells** infiltrating the skin, such as **carcinomas**, **melanoma**, or **lymphomas**.

c) Imaging:

- **CT scan**, **PET scan**, or **MRI** may be necessary to identify **underlying malignancies**, particularly if cutaneous signs suggest internal cancer.

d) Laboratory Tests:

1. **Complete blood count (CBC):**
 - Used to detect **hematologic malignancies** such as **leukemia** or **lymphoma**.
2. **Tumor markers:**
 - Tests such as **CA 19-9**, **CEA**, and **AFP** may be useful in cases where skin manifestations suggest an internal **malignancy**.

e) Other Tests:

- **Immunohistochemistry (IHC):** Helpful in identifying the origin of **cutaneous metastases** and distinguishing between **different types of malignancies**.

4. Explanation of Investigations:

- **Skin biopsy:** Confirms the presence of **malignant cells** or **paraneoplastic dermatoses**, providing crucial diagnostic information.
- **Imaging:** Detects the **primary tumour** or **metastases** to internal organs, especially if the cutaneous signs suggest malignancy.
- **Tumour markers:** Useful in screening for specific **cancers** based on **cutaneous findings**.

5. Diagnosis Criteria for Cutaneous Manifestations of Malignancy:

Diagnosis is based on:

- **Characteristic skin findings** (e.g., **cutaneous metastases**, **erythematous plaques**, or **hyperpigmented patches**).
- **History of cancer** or **paraneoplastic syndrome**.
- **Skin biopsy:** Histological evidence of **malignancy** or **inflammatory changes** related to a paraneoplastic syndrome.
- **Clinical correlation** with known **internal malignancies**, such as **lung**, **gastric**, or **breast cancer**.

6. First-Line Therapy According to Guidelines:

a) Treatment of the Underlying Malignancy:

- The key to managing cutaneous manifestations of malignancy is to **treat the primary cancer** (e.g., with **surgery**, **chemotherapy**, **radiotherapy**, or **targeted therapies**). Cutaneous lesions often resolve once the underlying cancer is treated.

b) Symptomatic Management:

1. **Topical corticosteroids:**
 - Used to manage **itching** and **inflammation** in conditions like **Sweet's syndrome** or **paraneoplastic dermatoses**.
2. **Systemic corticosteroids:**
 - High doses may be necessary for **inflammatory dermatoses** like **Sweet's syndrome**, particularly when the patient has significant systemic symptoms.
3. **Immunosuppressive agents:**
 - Drugs like **methotrexate** or **cyclosporine** can be used in **paraneoplastic dermatoses** such as **dermatomyositis** or **erythroderma** when severe.

4. Antibiotics or antifungal agents:

- In cases where **cutaneous infections** complicate the skin manifestations of cancer, prompt treatment with **antimicrobial therapy** is necessary.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Systemic corticosteroids** should be used with caution in patients with certain cancers, as they may **mask symptoms** or interfere with cancer treatment.

b) Second-Line Therapy:

1. Biologic agents:

- In conditions like **dermatomyositis** or **Sweet's syndrome** that do not respond to corticosteroids, **biologics** such as **infliximab** or **etanercept** may be considered.

2. Chemotherapy:

- For patients with **hematologic malignancies**, such as **leukemia cutis**, systemic chemotherapy is often required.

8. Routine Monitoring and Follow-Up:

- **Regular skin examinations** to monitor for new or worsening **cutaneous manifestations** of malignancy.
- **Imaging** and **tumour marker** tests to track the progression of the underlying cancer.
- **Biopsies** may be repeated if new skin lesions appear or if existing lesions change in appearance.

9. Complications:

1. Progression of the underlying malignancy:

- Untreated cutaneous manifestations may indicate the spread or worsening of the internal cancer.

2. Infection:

- Skin breakdown due to **metastases** or **paraneoplastic syndromes** can lead to **secondary bacterial infections**, which require prompt treatment

110. Vasculitis

1. Detailed Definition of Vasculitis:

Vasculitis refers to a group of disorders characterized by **inflammation of blood vessels**, which can lead to **vessel wall damage** and **compromised blood flow** to organs and tissues. This can result in **ischemia**, **necrosis**, and a wide range of organ-specific symptoms. Vasculitis can affect **large**, **medium**, and **small vessels**, and may be **primary** (idiopathic) or **secondary** to other diseases such as **autoimmune disorders**, **infections**, or **malignancies**.

2. Common Presenting Complaints and Symptoms:

a) Systemic Symptoms:

- **Fever**, **malaise**, **weight loss**, and **fatigue** are common in all types of vasculitis, especially in systemic forms.

b) Specific Symptoms Based on Vessel Size Affected:

Large Vessel Vasculitis (e.g., Giant Cell Arteritis, Takayasu's Arteritis):

1. Giant Cell Arteritis (GCA):

- **Headache** (temporal region), **jaw claudication**, and **scalp tenderness**.

- **Visual disturbances** (e.g., transient or permanent **vision loss**) due to ischemia of the optic nerve.
- **Polymyalgia rheumatica**: Associated with **pain and stiffness** in the **shoulders and hips**.

2. Takayasu's Arteritis:

- **Claudication** in arms or legs, **dizziness**, and **syncope**.
- **Absent or diminished pulses** in the upper extremities ("**pulseless disease**").
- **Blood pressure discrepancies** between arms and reduced arterial blood flow.

Medium Vessel Vasculitis (e.g., Polyarteritis Nodosa, Kawasaki Disease):

1. Polyarteritis Nodosa (PAN):

- **Skin manifestations**: **Livedo reticularis**, **purpura**, and **nodules**.
- **Peripheral neuropathy** (mononeuritis multiplex), **renal artery involvement** (causing **hypertension**), and **abdominal pain** (due to mesenteric ischemia).

2. Kawasaki Disease (children):

- **Fever**, **strawberry tongue**, **conjunctival injection**, **rash**, and **swollen hands/feet**.
- **Coronary artery aneurysms** are a significant complication, leading to risk of **myocardial infarction**.

Small Vessel Vasculitis (e.g., Granulomatosis with Polyangiitis, Microscopic Polyangiitis, Henoch-Schönlein Purpura):

1. Granulomatosis with Polyangiitis (GPA):

- **Sinusitis**, **nasal congestion**, **saddle-nose deformity** (due to nasal cartilage destruction), and **hemoptysis**.
- **Glomerulonephritis**, causing **haematuria** and **proteinuria**.
- **Pulmonary nodules** on imaging, leading to **dyspnea** or **cough**.

2. Microscopic Polyangiitis (MPA):

- Similar to GPA but without the **granulomatous inflammation**.
- **Renal involvement** (rapidly progressive glomerulonephritis) and **pulmonary haemorrhage**.

3. Henoch-Schönlein Purpura (HSP):

- **Palpable purpura** on the **buttocks** and **lower extremities**, **abdominal pain**, and **arthralgias**.
- Renal involvement may present as **haematuria** or **proteinuria**.

3. First-Line Investigations:

a) Blood Tests:

1. Complete blood count (CBC):

- May show **anaemia** and **leukocytosis** in systemic vasculitis.

2. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP):

- Both are typically **elevated** due to inflammation.

3. Renal function tests:

- Assess for **glomerulonephritis**, especially in **small vessel vasculitis** like GPA or MPA.

4. Autoantibodies:

- **Antineutrophil cytoplasmic antibodies (ANCA)**:
 - **c-ANCA (PR3-ANCA)** is associated with **GPA**.
 - **p-ANCA (MPO-ANCA)** is associated with **MPA** and **eosinophilic granulomatosis with polyangiitis (EGPA)**.

- **Antinuclear antibody (ANA):**
 - To rule out underlying **autoimmune conditions** like **systemic lupus erythematosus (SLE)**.

b) Urinalysis:

- Check for **haematuria**, **proteinuria**, and **red cell casts**, which indicate **glomerulonephritis** in small vessel vasculitis.

c) Imaging:

1. **Chest X-ray or CT:**
 - For **pulmonary involvement**, especially in **GPA** and **MPA**, showing **nodules** or **cavitary lesions**.
2. **Doppler ultrasound:**
 - Useful for assessing **large vessel vasculitis** like **Takayasu's arteritis** for vascular stenosis or occlusion.
3. **Angiography:**
 - In **PAN**, angiography can show **microaneurysms** in the kidneys, liver, or mesenteric vessels.

d) Biopsy:

- **Skin, kidney, or lung biopsy:**
 - Confirms diagnosis by showing evidence of **vasculitis** in small vessels, often with **granulomatous inflammation** or **necrosis**.

4. Explanation of Investigations:

- **ANCA antibodies:** Help to distinguish different types of **small vessel vasculitis**, such as **GPA** and **MPA**, where ANCA antibodies play a significant role.
- **Biopsy:** The definitive diagnosis for vasculitis, as it shows characteristic **inflammation of blood vessels** and tissue **necrosis**.

5. Diagnosis Criteria for Vasculitis:

Large Vessel Vasculitis:

- **Giant Cell Arteritis:** Clinical criteria include **age > 50 years**, **new headache**, **temporal artery tenderness** or decreased pulse, **elevated ESR**, and abnormal **arterial biopsy**.

Small Vessel Vasculitis:

- **GPA diagnosis:** Requires at least two of the following:
 1. **Nasal or oral inflammation.**
 2. **Lung involvement** (nodules or cavitation).
 3. **Renal involvement** (glomerulonephritis).
 4. **c-ANCA positivity** or characteristic **biopsy findings**.

6. First-Line Therapy According to Guidelines:

a) Corticosteroids:

1. **Prednisolone:**
 - Dosage: **1 mg/kg/day**, tapered slowly over several months.
 - **Mechanism:** Corticosteroids reduce **inflammation** by inhibiting the immune response.

b) Immunosuppressive Agents:

1. **Cyclophosphamide:**
 - Used in **severe vasculitis** such as **GPA** and **MPA**.

- **Mechanism:** Alkylating agent that suppresses the immune system by inhibiting lymphocyte proliferation.
- 2. **Methotrexate or Azathioprine:**
 - Used for **maintenance therapy** after achieving remission.
 - **Mechanism:** Inhibit immune cell proliferation, reducing inflammation.
- c) **Biologic Agents:**
 1. **Rituximab:**
 - Indicated for **ANCA-associated vasculitis**.
 - **Mechanism:** Targets **CD20+ B cells**, reducing autoantibody production.
 2. **Tocilizumab:**
 - Used for **Giant Cell Arteritis**.
 - **Mechanism:** **IL-6 receptor antagonist** that inhibits inflammation.
- d) **Antiplatelet or Anticoagulant Therapy:**
 - May be required in patients with **large vessel vasculitis** to prevent **thrombosis**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to Corticosteroids:

- **Diabetes** and **osteoporosis:** Patients with these conditions may experience worsening of symptoms with **long-term corticosteroid use**.

b) Second-Line Therapy:

- **Plasma exchange** (plasmapheresis):
 - Used in severe cases of **GPA** or **MPA** with life-threatening complications such as **pulmonary haemorrhage** or **rapidly progressive glomerulonephritis**.
-

8. Routine Monitoring and Follow-Up:

- **Monitor blood pressure** in patients with **renal involvement**.
- **Frequent blood tests** to assess for **renal function** and monitor for **side effects of immunosuppressive therapy** (e.g., **bone marrow suppression**, **liver toxicity**).
- **Urinalysis:** Regularly monitor for **proteinuria**, **haematuria**, or signs of **worsening renal function**.
- **ESR/CRP:** Track **inflammatory markers** to assess the activity of vasculitis and response to treatment.
- **Lung function tests:** Monitor pulmonary involvement, particularly in **GPA** and **MPA** patients who are at risk for **pulmonary haemorrhage** or **fibrosis**.
- **Imaging:** Periodic **CT scans** or **ultrasounds** to assess the progression of **vascular involvement**, especially in large vessel vasculitis like **Takayasu's arteritis**.

9. Complications:

1. **Renal failure:**
 - A common complication of **small vessel vasculitis** like **GPA** and **MPA**, leading to **chronic kidney disease** if left untreated.
2. **Pulmonary haemorrhage:**
 - Seen in **small vessel vasculitis** (e.g., **GPA**, **MPA**) and can lead to **life-threatening respiratory failure**.
3. **Vision loss:**
 - In **Giant Cell Arteritis**, **optic nerve ischemia** can lead to **permanent blindness** if treatment is delayed.
4. **Aneurysms and stenosis:**

- **Medium vessel vasculitis** (e.g., **PAN**) can cause **aneurysm formation**, while **large vessel vasculitis** (e.g., **Takayasu's arteritis**) can result in **vascular stenosis**, increasing the risk of **stroke** or **myocardial infarction**.
5. **Infections:**
- Immunosuppressive therapy increases the risk of **opportunistic infections**, which requires careful monitoring and sometimes prophylactic treatment.

Summary of Key Points for Vasculitis:

- **Vasculitis** is an umbrella term for disorders characterized by **blood vessel inflammation**, with different subtypes affecting **large, medium, or small vessels**.
- **Diagnosis** is based on **clinical presentation, blood tests (ANCA), biopsy, and imaging** to confirm vascular involvement.
- **First-line treatment** generally includes **corticosteroids** and **immunosuppressive agents**, with **biologic therapies** for refractory cases.
- Regular **monitoring** for complications such as **renal failure, pulmonary haemorrhage, and vascular stenosis** is crucial.
- Early recognition and **prompt treatment** are key to preventing long-term damage and life-threatening complications.

111. Erythema Nodosum

1. Detailed Definition of Erythema Nodosum:

Erythema nodosum (EN) is a type of **panniculitis** (inflammation of the subcutaneous fat), characterized by the sudden onset of **tender, red or violet nodules**, typically on the **anterior shins**. It is often a **hypersensitivity reaction** triggered by a variety of infections, medications, or systemic conditions. The lesions are usually **bilateral** and self-limiting, resolving over several weeks. Erythema nodosum is frequently associated with **infections, autoimmune diseases, medications, or pregnancy**, and may also be idiopathic.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Tender, red nodules:**
 - Typically located on the **anterior shins**, but can also appear on other areas such as the **arms, thighs, or trunk**.
 - The nodules evolve from **red** to **violet** and then resolve, often leaving **bruising** behind.
- **Symmetry:**
 - Lesions are usually **bilaterally symmetric**, but not always.

b) Systemic Symptoms:

- **Fever, malaise, arthralgia** (joint pain), and **fatigue**.
- **Swelling of joints:** **Ankle** and **knee** joints are commonly affected.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Identify the **typical lesions** of erythema nodosum on the **shins** or other extremities.
- **Palpation:** Nodules are **tender**, firm, and not fluctuant.

b) Blood Tests:

1. **Complete blood count (CBC):**

- Look for **leukocytosis**, which may suggest an **infectious** or **inflammatory trigger**.
- 2. **Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP):**
 - Both are typically **elevated**, reflecting the underlying **inflammatory process**.
- 3. **Throat swab or serology:**
 - To detect **streptococcal infection**, a common cause of erythema nodosum, particularly in children.
- 4. **Tuberculosis (TB) screening:**
 - Perform a **Mantoux test** or **interferon-gamma release assay (IGRA)**, especially in endemic regions, as **TB** can be a trigger for erythema nodosum.

c) Imaging:

- **Chest X-ray:**
 - To rule out **sarcoidosis**, a common cause of erythema nodosum, and look for **bilateral hilar lymphadenopathy** or lung involvement.

4. Explanation of Investigations:

- **CBC and inflammatory markers:** Help detect **underlying infections** or **inflammatory disorders**.
- **TB screening:** Given that **tuberculosis** is a well-known cause of erythema nodosum, ruling out this infection is essential in endemic areas.
- **Chest X-ray:** Important to rule out **sarcoidosis**, which often presents with **erythema nodosum** as the first symptom.

5. Diagnosis Criteria for Erythema Nodosum:

Diagnosis of erythema nodosum is typically **clinical**:

1. **Tender red nodules** on the shins, which may extend to other areas.
2. **Symmetry** of lesions.
3. **Systemic symptoms** like fever, fatigue, and joint pain often accompany the skin findings.

A combination of the above clinical findings, **raised inflammatory markers**, and a **clear underlying cause** (if identified) supports the diagnosis.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

1. **Rest:**
 - Encourage **bed rest** and **elevation** of the legs to reduce **inflammation** and **pain**.
2. **Compression stockings:**
 - Can help alleviate **swelling** and discomfort in the legs.

b) Anti-inflammatory Medications:

1. **Non-steroidal anti-inflammatory drugs (NSAIDs):**
 - **Ibuprofen** or **naproxen** can reduce **pain**, **swelling**, and **inflammation**.
 - **Mechanism:** Inhibit cyclooxygenase (COX) enzymes, reducing the production of **pro-inflammatory prostaglandins**.

c) Treat Underlying Cause:

- If erythema nodosum is linked to **infection** (e.g., **streptococcal throat infection**), treat the underlying infection with the appropriate **antibiotic therapy** (e.g., **penicillin** for streptococcal infections).

- If caused by **medications**, such as **oral contraceptives** or **antibiotics**, discontinue the triggering drug.

d) Corticosteroids:

- For **severe or prolonged cases**, systemic **corticosteroids** like **prednisolone** may be used to suppress the immune system.
 - **Mechanism:** Reduce **inflammation** by inhibiting multiple inflammatory pathways.

7. Contraindications and Second-Line Therapy:

a) Contraindications:

- **Corticosteroids** should be used with caution in cases where the underlying cause is **infectious**, as they may exacerbate the infection.

b) Second-Line Therapy:

1. **Colchicine** or **potassium iodide**:
 - May be used in **chronic** or **recurrent erythema nodosum** cases that are not responding to first-line therapy.
 - **Mechanism:** Reduces **neutrophil activity**, which plays a role in the inflammatory process of erythema nodosum.
2. **Dapsone** or **Hydroxychloroquine**:
 - For patients with **underlying autoimmune diseases** such as **sarcoidosis** or **inflammatory bowel disease (IBD)**, these agents may be used.

8. Routine Monitoring and Follow-Up:

- **Follow-up visits** to monitor the **resolution** of the skin lesions and assess for **new systemic symptoms**.
- **Repeat blood tests** (CBC, ESR, CRP) to ensure resolution of the **underlying cause**.
- For **chronic or recurrent cases**, referral to a **rheumatologist** or **dermatologist** for further evaluation may be needed, especially if underlying **autoimmune** or **inflammatory conditions** are suspected.

9. Complications:

1. **Chronic erythema nodosum**:
 - Although rare, some patients may experience **persistent or recurrent episodes**, particularly in association with **chronic inflammatory diseases** such as **sarcoidosis** or **inflammatory bowel disease**.
2. **Hyperpigmentation** or **bruising**:
 - Lesions may leave **post-inflammatory hyperpigmentation** or residual **bruising** as they heal, particularly in individuals with **darker skin tones**.
3. **Joint pain**:
 - Patients with erythema nodosum may experience prolonged **arthralgia**, especially in the **ankles** or **knees**.
4. **Misdiagnosis**:
 - In some cases, the underlying cause of erythema nodosum may not be identified, leading to delayed or inappropriate treatment. Careful evaluation for **systemic conditions** is crucial.

Summary of Key Points for Erythema Nodosum:

- **Erythema nodosum** is a type of **panniculitis** presenting with **tender, red nodules** typically on the **shins** and is often linked to **infections, medications, or systemic diseases**.
- Diagnosis is primarily **clinical**, with supporting tests like **CBC, ESR/CRP**, and **chest X-ray** (for sarcoidosis).
- **First-line therapy** includes **NSAIDs, rest**, and treating the **underlying cause**.
- In **chronic or severe cases**, **corticosteroids** or second-line agents like **colchicine** may be used.
- Routine follow-up is important to monitor the resolution of symptoms and to ensure the underlying condition is treated.

112. Erythema Multiforme

1. Detailed Definition of Erythema Multiforme:

Erythema multiforme (EM) is an **acute, immune-mediated condition** characterized by the appearance of **target-like lesions** on the skin, often accompanied by **mucosal involvement**. It is typically triggered by **infections** (most commonly **herpes simplex virus**) or **medications**. EM is classified into two major subtypes:

- **Erythema multiforme minor:** Involves **target lesions** with minimal or no mucosal involvement.
- **Erythema multiforme major:** More severe, with widespread **target lesions** and significant **mucosal involvement**.

EM is **self-limiting** in most cases but can be recurrent, particularly when linked to viral infections like **herpes simplex**.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Target lesions:**
 - **Classic sign:** Lesions with three concentric zones of colour change—**dark center, pale middle ring**, and **red outer ring**.
 - Lesions are typically **symmetric** and can appear on the **extremities, palms, soles, back of hands**, and **feet**.
 - May evolve into **blisters** or **erosions**.
- **Distribution:**
 - The lesions often begin on the **hands** and **feet** and spread to the **trunk** and **face**.

b) Mucosal Involvement:

- **Erythema multiforme major** often presents with **painful mucosal erosions** in the **oral cavity, eyes**, or **genital region**.
- **Lip swelling** and **ulcers** can also occur, making eating and drinking painful.

c) Systemic Symptoms:

- **Fever, malaise**, and **arthralgia** (joint pain) may accompany the skin findings.
- **Mild itchiness** or **burning sensation** in the skin may be present.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Identify the **classic target lesions** and assess the extent of **mucosal involvement**.
- **Palpation:** Lesions are typically **non-tender**.

b) Blood Tests:

1. **Complete blood count (CBC):**
 - May show **leukocytosis** in the presence of an infection.
2. **Inflammatory markers:**
 - **C-reactive protein (CRP)** and **erythrocyte sedimentation rate (ESR)** may be elevated if systemic inflammation is present.

c) Viral Serology:

- **Herpes simplex virus (HSV)** testing (PCR or serology):
 - Often linked to recurrent erythema multiforme, especially if outbreaks of **oral/genital herpes** occur.

d) Skin Biopsy (if diagnosis is unclear):

- Histology typically shows **epidermal necrosis**, **vacuolar degeneration**, and **dermal inflammation**.
- A biopsy can help distinguish EM from other blistering skin disorders like **Stevens-Johnson syndrome (SJS)** or **toxic epidermal necrolysis (TEN)**.

e) Chest X-ray (in some cases):

- Performed if there is suspicion of an underlying **Mycoplasma pneumoniae** infection, which can trigger EM.

4. Explanation of Investigations:

- **Viral serology (HSV):** Erythema multiforme is often triggered by **herpes simplex virus**, particularly recurrent infections. Detecting active infection helps guide **antiviral therapy**.
- **Skin biopsy:** Confirms the diagnosis by identifying **characteristic histological features** of EM and rules out more severe conditions like **SJS** or **TEN**.

5. Diagnosis Criteria for Erythema Multiforme:

Diagnosis of erythema multiforme is primarily **clinical**, based on:

1. Presence of **target lesions** with three zones.
2. Symmetry of lesions, typically starting on the **extremities**.
3. **Mucosal involvement** in more severe cases (erythema multiforme major).
4. History of **triggering factors**, particularly **herpes simplex virus infection** or recent **medication use**.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

1. **Symptomatic management:**
 - **Topical corticosteroids** for mild skin lesions to reduce inflammation and relieve symptoms.
 - **Analgesics** like **acetaminophen** or **NSAIDs** to manage fever and joint pain.
 - **Oral antihistamines** can help relieve **itching**.
2. **Hydration and oral care:**
 - In cases with significant **mucosal involvement**, provide **oral rinses** (e.g., **saltwater** or **chlorhexidine**) to promote healing and reduce pain.

b) Antiviral Therapy (for HSV-related EM):

1. **Acyclovir:**
 - Dosage: **200 mg 5 times a day for 5-10 days**.
 - **Mechanism:** Inhibits **HSV DNA replication**, preventing or reducing recurrent outbreaks that trigger erythema multiforme.

2. **Valacyclovir or famciclovir:**

- May be used for **chronic suppression** of HSV to prevent recurrent episodes of EM.

c) Corticosteroids (for severe cases):

1. **Systemic corticosteroids** (e.g., **prednisolone**):

- Dosage: **30-60 mg daily**, tapered as symptoms improve.
- **Mechanism:** Reduces **inflammation** and suppresses the immune response in cases of erythema multiforme major with extensive skin and mucosal involvement.

d) Treat Underlying Causes:

• **Antibiotic therapy:**

- If triggered by a bacterial infection such as **Mycoplasma pneumoniae**, treat the underlying infection with **antibiotics** (e.g., **macrolides** like **azithromycin**).

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Systemic corticosteroids** should be used cautiously in patients with active **infections** (e.g., **HSV**), as they may exacerbate the infection.

b) Second-Line Therapy:

1. **Intravenous immunoglobulin (IVIG):**

- Used in **severe or recurrent cases** where first-line treatments are ineffective.
- **Mechanism:** Modulates immune response and helps prevent further progression of inflammation.

2. **Dapsone or Hydroxychloroquine:**

- Can be considered for **chronic or recurrent cases** of erythema multiforme not responding to antiviral therapy or corticosteroids.

8. Routine Monitoring and Follow-Up:

- **Monitor skin lesions** to ensure **resolution** and watch for **recurrence**, especially in cases triggered by **HSV**.
- **Regular viral serology testing** (for HSV) may be necessary for patients with recurrent episodes.
- For severe cases, **follow-up visits** to monitor **steroid tapering** and ensure no **side effects** of immunosuppressive therapy.

9. Complications:

1. **Progression to Stevens-Johnson syndrome (SJS) or Toxic Epidermal Necrolysis (TEN):**

- Though EM is usually **benign**, in rare cases, it may progress to **SJS** or **TEN**, which involve **widespread epidermal detachment** and can be life-threatening.

2. **Mucosal scarring:**

- Severe cases of erythema multiforme major with extensive **mucosal erosions** may lead to **scarring** in the oral, ocular, or genital mucosa.

3. **Recurrent episodes:**

- Erythema multiforme is often **recurrent**, particularly when linked to **HSV** infections. Chronic suppression with **antivirals** may be required.

4. **Secondary infections:**

- Erosions and blistered skin are prone to **secondary bacterial infections**, requiring **antibiotic therapy** if infection occurs.

Summary of Key Points for Erythema Multiforme:

- **Erythema multiforme** is an acute condition characterized by **target-like lesions**, usually triggered by **infections** (most commonly **HSV**) or **medications**.
- **Diagnosis** is clinical, with **target lesions** as a hallmark and **mucosal involvement** in severe cases.
- **First-line therapy** includes **supportive care**, **antiviral treatment** for HSV-related cases, and **systemic corticosteroids** for severe cases.
- Close **monitoring** for progression to **SJS/TEN** and managing **recurrence** in chronic cases is crucial.

113. Pyoderma Gangrenosum

1. Detailed Definition of Pyoderma Gangrenosum:

Pyoderma gangrenosum (PG) is a rare, **inflammatory skin condition** characterized by rapidly progressing, **painful ulcers** with **necrotic** bases and **violaceous** undermined borders. PG is not an infectious condition but is thought to result from **dysregulated immune activity**, often associated with underlying systemic diseases, such as **inflammatory bowel disease**, **rheumatoid arthritis**, and **hematologic malignancies**. The exact pathogenesis is unclear, but it is believed to involve **neutrophil dysfunction**.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Ulcerated lesions:**
 - Typically begins as a **painful pustule** or **nodule** that breaks down into an **ulcer** with a characteristic **violaceous border**.
 - The ulcers have **irregular edges**, are **deep**, and may have a **purulent base**.
- **Location:**
 - Most commonly on the **lower extremities** (e.g., **shins**), but may also appear on the **trunk**, **arms**, or **face**.
- **Rapid progression:**
 - Lesions can enlarge quickly and cause significant **pain**.

b) Systemic Symptoms:

- **Fever**, **malaise**, and **fatigue** may accompany the skin lesions, particularly if there is associated underlying systemic disease.

c) Associated Conditions:

- Pyoderma gangrenosum is often associated with systemic diseases, including:
 - **Inflammatory bowel disease** (Crohn's disease and ulcerative colitis).
 - **Rheumatoid arthritis**.
 - **Hematologic malignancies** (e.g., **leukemia**, **myelodysplastic syndromes**).
 - **Monoclonal gammopathy**.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:** Identify **painful ulcers** with **violaceous undermined borders**.
- **Palpation:** Ulcers are tender, and surrounding tissues may show signs of inflammation.

b) Blood Tests:

1. **Complete blood count (CBC):**

- May show **anaemia, leukocytosis, or thrombocytosis**, especially if associated with an underlying systemic condition.

2. **Inflammatory markers:**

- **Erythrocyte sedimentation rate (ESR)** and **C-reactive protein (CRP)** are usually elevated, indicating underlying **inflammation**.

3. **Liver function tests and renal function tests:**

- Helps assess overall systemic health, particularly in patients with chronic underlying diseases.

c) Microbiological Testing:

- Although **PG** is **not infectious**, **wound cultures** may be obtained to rule out secondary **bacterial infection** of the ulcer.

d) Skin Biopsy (to rule out other causes):

- Histological findings of **PG** include **neutrophilic infiltration** in the **dermis** with tissue **necrosis**.
- A biopsy helps exclude other causes of **ulceration**, such as **vasculitis, infection, or malignancy**.

e) Imaging (in cases of suspected associated systemic disease):

- **Colonoscopy:** To assess for **inflammatory bowel disease** in patients with gastrointestinal symptoms.
- **Chest X-ray or CT scan:** In cases of suspected **pulmonary involvement** or underlying **malignancy**.

4. Explanation of Investigations:

- **Skin biopsy:** The hallmark finding in PG is **neutrophilic infiltration**, but biopsy is mainly done to rule out other conditions (e.g., **infection, vasculitis, malignancy**) that can mimic PG.
- **Blood tests:** Elevated **ESR** and **CRP** suggest active **inflammation**, while **CBC** abnormalities may hint at an associated systemic disease.

5. Diagnosis Criteria for Pyoderma Gangrenosum:

Pyoderma gangrenosum is primarily diagnosed **clinically** through exclusion:

1. **Painful, rapidly progressive ulcers** with a **violaceous border**.
2. **No infectious cause** identified on **cultures**.
3. Association with **underlying systemic diseases**, such as **IBD, rheumatoid arthritis, or hematologic malignancy**.
4. **Biopsy** findings of **neutrophilic dermatosis**, though biopsy is not always necessary if the clinical picture is clear.

6. First-Line Therapy According to Guidelines:

a) Local Wound Care:

1. **Wound dressings:**

- **Non-adherent or hydrocolloid dressings** are recommended to promote healing and prevent trauma.
- **Topical antibiotics** are sometimes used if there is a secondary infection.

b) Systemic Corticosteroids:

1. **Prednisolone:**

- Dosage: **0.5-1 mg/kg/day**, tapered as the ulcers begin to heal.

- **Mechanism:** Suppresses the immune system, reducing **inflammation** and **neutrophil activity**.

c) Immunosuppressive Agents:

1. **Cyclosporine:**
 - Used for patients with **severe or refractory PG**.
 - **Mechanism:** Inhibits T-cell activation and reduces **immune-mediated damage**.
2. **Azathioprine or Methotrexate:**
 - Often used for **steroid-sparing** therapy, particularly in patients with associated **autoimmune conditions**.
 - **Mechanism:** Inhibits lymphocyte proliferation and reduces **inflammation**.

d) Biologics:

1. **Anti-TNF agents** (e.g., **infliximab** or **adalimumab**):
 - Used for patients with **refractory PG** or those with **underlying IBD**.
 - **Mechanism:** Blocks the action of **tumour necrosis factor-alpha (TNF-α)**, which plays a role in **inflammatory pathways**.

7. Contraindications and Second-Line Therapy:

a) Contraindications:

- **Corticosteroids** should be used with caution in patients with **diabetes** or **active infection**, as steroids can worsen blood sugar control and increase susceptibility to infections.

b) Second-Line Therapy:

1. **Intravenous immunoglobulin (IVIG):**
 - Can be used in **refractory cases** of PG where other treatments have failed.
 - **Mechanism:** Modulates immune system activity and helps control inflammation.
2. **Plasma exchange:**
 - Used in cases where **immunosuppressive therapy** is ineffective.

8. Routine Monitoring and Follow-Up:

- **Wound healing:** Regular follow-up to assess the healing of ulcers and check for any signs of **secondary infection**.
- **Blood tests:** Monitor **CBC**, **ESR**, and **CRP** levels to assess the response to treatment and monitor for any adverse effects of **immunosuppressive therapy**.
- **Liver and kidney function tests:** Especially important for patients on **immunosuppressants** such as **methotrexate** or **cyclosporine**.

9. Complications:

1. **Secondary bacterial infection:**
 - Since the ulcers are deep and may become **purulent**, there is a risk of **secondary infection**, which requires **antibiotic therapy**.
2. **Scarring:**
 - Healed PG ulcers often leave **atrophic scars**, and in some cases, the scarring may be **disfiguring**.
3. **Relapses:**
 - PG is prone to **recurrence**, particularly in patients with **underlying systemic conditions** such as **inflammatory bowel disease** or **rheumatoid arthritis**.
4. **Adverse effects of systemic therapy:**

- **Long-term corticosteroid use** can lead to **osteoporosis**, **hyperglycaemia**, and **adrenal suppression**.
- **Immunosuppressive drugs** increase the risk of **opportunistic infections** and **malignancy**.

Summary of Key Points for Pyoderma Gangrenosum:

- **Pyoderma gangrenosum (PG)** is a rare **neutrophilic dermatosis** characterized by **painful, rapidly progressing ulcers** with **violaceous borders**.
- It is often associated with **systemic conditions** such as **inflammatory bowel disease**, **rheumatoid arthritis**, or **hematologic malignancies**.
- Diagnosis is **clinical**, and a **skin biopsy** may be used to rule out other causes of ulceration.
- **First-line therapy** involves **corticosteroids** and **immunosuppressive agents**, with **anti-TNF agents** reserved for refractory cases.
- **Regular monitoring** is essential to assess wound healing, monitor for recurrence, and manage side effects of **immunosuppressive therapy**.

114. Venous Ulcers

1. Detailed Definition of Venous Ulcers:

Venous ulcers, also known as **venous stasis ulcers**, are chronic, slow-healing wounds that occur primarily on the **lower legs**, particularly around the **medial malleolus** (inner ankle). They result from **chronic venous insufficiency (CVI)**, where the valves in the veins are incompetent, causing **venous stasis** and **hypertension**. This increased pressure in the veins leads to **skin breakdown** and ulcer formation. Venous ulcers are the most common type of **leg ulcers**, accounting for 70-90% of all lower extremity ulcers.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Open wound/ulcer:**
 - Typically located on the **medial malleolus** but may also occur on the **lateral ankle** or **lower leg**.
 - The ulcers are usually **shallow** with **irregular borders** and are **wet** or **exudative**, often with **yellow fibrin** at the base.
- **Surrounding skin changes:**
 - **Hyperpigmentation** (brown discoloration) caused by the deposition of **hemosiderin** from red blood cell breakdown.
 - **Lipodermatosclerosis**: A hardened, woody appearance of the skin due to chronic inflammation and fibrosis.
 - **Atrophie blanche**: White, scar-like areas seen in chronic venous disease.
- **Oedema:**
 - Swelling in the affected leg, which is usually more pronounced at the end of the day.

b) Symptoms of Venous Insufficiency:

- **Leg heaviness**, **aching**, or **pain** that worsens with prolonged standing and is relieved by **elevation**.
- **Itching** and **dry skin** around the ulcer site.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Identify the typical **location** (usually over the **medial malleolus**) and appearance of the ulcer, including the **shallow depth, irregular borders, and exudative base**.
- **Palpation:**
 - Assess for **pitting oedema** and **skin hardness** (lipodermatosclerosis) around the ulcer.

b) Ankle-Brachial Pressure Index (ABPI):

- Used to rule out **arterial insufficiency** in patients with venous ulcers.
- ABPI > 0.8 suggests that **venous insufficiency** is the primary cause, while an ABPI < 0.5 indicates significant **arterial disease**, which may contraindicate compression therapy.

c) Doppler Ultrasound:

- **Duplex ultrasound** is the gold standard for assessing **venous insufficiency**.
- Used to identify **venous reflux, venous obstruction, or deep vein thrombosis (DVT)**.

d) Blood Tests (optional):

1. **Complete blood count (CBC):**
 - To assess for **anaemia** or signs of **infection** (e.g., elevated white cell count).
2. **Blood glucose/HbA1c:**
 - Rule out **diabetes**, a common contributing factor in patients with poor wound healing.

e) Wound culture (if signs of infection):

- **Swab cultures** are taken if the ulcer shows signs of **infection** (e.g., increased exudate, foul odour, surrounding erythema).

4. Explanation of Investigations:

- **ABPI** helps differentiate between **venous** and **arterial ulcers**, as venous ulcers can be worsened or complicated by co-existing **arterial insufficiency**.
- **Doppler ultrasound** is essential to confirm the diagnosis of **chronic venous insufficiency** and to assess the need for interventions like **compression therapy** or **venous surgery**.

5. Diagnosis Criteria for Venous Ulcers:

Venous ulcers are diagnosed **clinically** based on:

1. **Location:** Ulcers typically over the **medial malleolus**.
2. **Appearance:** **Shallow, irregular-shaped, with wet or exudative base**.
3. **Surrounding signs of venous insufficiency:** **Oedema, hyperpigmentation, and lipodermatosclerosis**.
4. **ABPI > 0.8:** Indicates venous insufficiency without significant arterial involvement.

6. First-Line Therapy According to Guidelines:

a) Compression Therapy:

1. **Graduated compression bandages or stockings:**
 - **30-40 mmHg compression** is typically used to improve **venous return**, reduce **oedema**, and accelerate ulcer healing.
 - **Mechanism:** Compression decreases **venous stasis**, promotes **blood flow**, and improves **lymphatic drainage**.

b) Wound Care:

1. **Debridement:**

- Removal of **necrotic tissue** or **slough** from the ulcer base to promote **healing**. This can be done **mechanically**, **enzymatically**, or **surgically**.

2. **Wound dressings:**

- Use **moisture-retentive dressings** (e.g., **hydrocolloid**, **foam**, or **alginate dressings**) to maintain an optimal **healing environment**.
- **Antimicrobial dressings** (e.g., **silver** or **iodine-based dressings**) can be used if there is evidence of **infection**.

c) **Pharmacotherapy:**

1. **Pentoxifylline:**

- Dosage: **400 mg orally 2-3 times daily**.
- **Mechanism:** Improves **microcirculation** and decreases **blood viscosity**, which may help promote ulcer healing when combined with **compression therapy**.

2. **Aspirin:**

- **Low-dose aspirin** (75 mg daily) may improve healing rates in patients with venous ulcers by reducing **platelet aggregation** and improving **blood flow**.

d) **Treatment of Underlying Cause:**

1. **Venous surgery** (in some cases):

- **Endovenous ablation**, **sclerotherapy**, or **ligation** of incompetent veins may be indicated for patients with **chronic venous insufficiency** not responding to conservative measures.

2. **Management of comorbidities:**

- Optimize control of conditions such as **diabetes**, **obesity**, and **hypertension**, which can delay healing.

7. **Contraindications and Second-Line Therapy:**

a) **Contraindications to Compression Therapy:**

- **Significant arterial disease (ABPI < 0.5):** Compression therapy may worsen ischemia in patients with co-existing **arterial insufficiency**.

b) **Second-Line Therapy:**

1. **Skin grafting:**

- For large or non-healing ulcers, **split-thickness skin grafts** may be used to promote **wound closure**.

2. **Negative Pressure Wound Therapy (NPWT):**

- Also known as **vacuum-assisted closure (VAC)**, this therapy promotes **healing** by applying **negative pressure** to the wound, stimulating **granulation tissue formation** and **removing excess fluid**.

8. **Routine Monitoring and Follow-Up:**

- **Regular wound assessments** to monitor for **healing** and detect signs of **infection**.
- **Measurement of ulcer size** at each follow-up visit to assess progress.
- **Compression therapy adherence:** Patients should be encouraged to wear **compression stockings** even after the ulcer heals to prevent recurrence.
- **Blood glucose monitoring:** In patients with **diabetes**, ensure strict glycaemic control to promote wound healing.

9. **Complications:**

1. **Infection:**

- Venous ulcers can become secondarily infected, leading to **cellulitis**, **osteomyelitis**, or **sepsis** if not treated promptly.
- 2. **Chronic pain:**
 - Some patients may experience **persistent pain** around the ulcer despite adequate wound care, often due to **underlying inflammation** or **venous hypertension**.
- 3. **Recurrent ulceration:**
 - Even after healing, venous ulcers have a high rate of **recurrence** unless **compression therapy** is continued.
- 4. **Venous eczema** (stasis dermatitis):
 - Chronic venous insufficiency can lead to **itching**, **scaling**, and **redness** around the ulcer.
- 5. **Lipodermatosclerosis:**
 - Chronic inflammation may cause **fibrosis** and **hardening** of the skin, further impairing venous return and delaying healing.

Summary of Key Points for Venous Ulcers:

- **Venous ulcers** are chronic wounds primarily located on the **lower legs**, often associated with **chronic venous insufficiency**.
- **Diagnosis** is clinical, confirmed by **ABPI** to rule out arterial insufficiency and **Doppler ultrasound** to assess venous reflux.
- **First-line treatment** includes **compression therapy**, appropriate **wound care**, and treatment of any underlying **systemic conditions**.
- **Regular follow-up** is essential to monitor healing, prevent infection, and ensure adherence

115. Pemphigus Vulgaris

1. Detailed Definition of Pemphigus Vulgaris:

Pemphigus vulgaris is a rare, chronic, and potentially life-threatening **autoimmune blistering disorder** characterized by the formation of **intraepidermal blisters** on the skin and mucous membranes. It occurs due to the production of **autoantibodies** against **desmogleins** (proteins essential for keratinocyte adhesion) in the **epidermis**, leading to the loss of cell-to-cell adhesion (a process called **acantholysis**). This results in fragile blisters that easily rupture, causing painful erosions. **Pemphigus vulgaris** is the most common form of **pemphigus**.

2. Common Presenting Complaints and Symptoms:

a) Mucosal Symptoms:

- **Oral mucosal lesions:**
 - **Painful erosions** in the **mouth** are often the initial presentation. Patients may report **difficulty eating**, **drinking**, or **speaking**.
 - The **buccal mucosa**, **palate**, and **gingiva** are commonly affected.
- **Other mucosal involvement:**
 - **Oropharynx**, **genital mucosa**, **conjunctiva**, and **esophagus** can also be affected, causing **pain** and **erosions**.

b) Skin Symptoms:

- **Flaccid blisters:**
 - Fragile, superficial blisters filled with clear fluid, often found on **non-mucosal skin**. These blisters rupture easily, leaving **painful erosions** and **crusting**.

- The skin around the **scalp, face, chest, back, and intertriginous areas** is commonly affected.
- **Positive Nikolsky sign:**
 - Gentle pressure on normal-looking skin near a lesion causes the epidermis to **shear off**, indicating **epidermal detachment**.

c) Systemic Symptoms:

- **Weight loss, fatigue, and malaise** may occur, especially if mucosal involvement limits oral intake.
- **Secondary infections** are common due to open erosions.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Identify **flaccid blisters, erosions, and crusting** on the skin and mucosa.
 - Check for a **positive Nikolsky sign** by applying gentle lateral pressure near a lesion.

b) Skin and Mucosal Biopsy:

1. **Histopathology:**
 - Shows **intraepidermal acantholysis** (separation of epidermal cells) and **suprabasal clefting**.
2. **Direct immunofluorescence (DIF):**
 - Demonstrates **IgG and C3 deposits** in the intercellular spaces of the epidermis, confirming the diagnosis of **pemphigus vulgaris**.

c) Indirect Immunofluorescence and ELISA (for circulating antibodies):

- **Detection of circulating anti-desmoglein 1 and 3 antibodies** in the patient's serum is highly specific for **pemphigus vulgaris**.

d) Blood Tests:

1. **Complete blood count (CBC):**
 - To monitor for **anaemia** or signs of **infection**, especially in severe cases.
2. **Renal and liver function tests:**
 - To assess the patient's overall health and monitor for any **treatment-related toxicity** (particularly from immunosuppressive therapy).

4. Explanation of Investigations:

- **Direct immunofluorescence (DIF):** The hallmark diagnostic test for pemphigus vulgaris. It detects **IgG autoantibodies** deposited in the intercellular spaces of the **epidermis**, confirming the autoimmune nature of the disease.
- **ELISA:** Measures the levels of **circulating anti-desmoglein antibodies**, which are responsible for disrupting keratinocyte adhesion, leading to blister formation.

5. Diagnosis Criteria for Pemphigus Vulgaris:

Pemphigus vulgaris is diagnosed based on:

1. **Clinical presentation:** Presence of **flaccid blisters and erosions** on mucosal and non-mucosal skin, with a **positive Nikolsky sign**.
2. **Histopathological findings:** **Intraepidermal acantholysis** (detachment of epidermal cells).
3. **Direct immunofluorescence:** Demonstration of **IgG and C3 deposits** in the intercellular spaces of the epidermis.

4. **Serology:** Detection of **anti-desmoglein 1 and 3 antibodies** in the serum using ELISA or indirect immunofluorescence.

6. First-Line Therapy According to Guidelines:

a) Systemic Corticosteroids:

1. **Prednisolone:**
 - Dosage: **1-2 mg/kg/day** orally, depending on disease severity, and tapered once control is achieved.
 - **Mechanism:** Reduces inflammation and suppresses the immune system by inhibiting the activity of **autoantibodies** against desmogleins.

b) Immunosuppressive Agents:

1. **Azathioprine or Mycophenolate mofetil:**
 - Used as **steroid-sparing agents** to reduce the dose of corticosteroids required and to maintain long-term control.
 - **Mechanism:** Inhibits lymphocyte proliferation, reducing the production of **autoantibodies**.
2. **Cyclophosphamide or Methotrexate:**
 - May be used in **refractory cases** or for patients who cannot tolerate other immunosuppressive agents.

c) Biologic Therapy:

1. **Rituximab:**
 - A monoclonal antibody that targets **CD20-positive B cells**, reducing the production of **anti-desmoglein antibodies**.
 - **Rituximab** is increasingly used as a **first-line treatment** for moderate to severe cases of **pemphigus vulgaris** due to its high efficacy and steroid-sparing benefits.

d) Supportive Care:

1. **Wound care:**
 - **Topical antibiotics** or **antiseptics** may be applied to prevent secondary infection of open erosions.
2. **Pain management:**
 - **Analgesics** such as **paracetamol** or **NSAIDs** for pain control, especially in cases with extensive mucosal involvement.
3. **Oral hygiene:**
 - **Chlorhexidine mouthwashes** or **saltwater rinses** to reduce discomfort and prevent secondary infections in oral erosions.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Systemic corticosteroids** can cause significant **side effects** (e.g., **osteoporosis**, **hyperglycaemia**, **hypertension**), so careful monitoring and use of **steroid-sparing agents** (e.g., **azathioprine**, **rituximab**) is recommended.

b) Second-Line Therapy:

1. **Intravenous immunoglobulin (IVIG):**
 - May be used for patients with **refractory pemphigus vulgaris** or those intolerant to standard immunosuppressive therapy.
 - **Mechanism:** IVIG provides **passive immunity** and modulates the immune system by inhibiting **autoantibody production**.

2. Plasmapheresis:

- In cases of **severe, resistant pemphigus**, **plasmapheresis** may be used to remove circulating **autoantibodies** from the blood.

8. Routine Monitoring and Follow-Up:

- **Regular blood tests:** Monitor for side effects of immunosuppressive therapy, including **CBC**, **liver function tests**, and **renal function**.
- **Anti-desmoglein antibody levels:** Can be measured periodically to track disease activity and response to treatment.
- **Bone density monitoring:** Long-term corticosteroid use increases the risk of **osteoporosis**, so **DEXA scans** may be indicated.

9. Complications:

1. Secondary infections:

- Open erosions on the skin and mucous membranes are prone to **bacterial infections**, which can lead to **sepsis** if not properly managed.

2. Corticosteroid-related complications:

- Long-term use of **systemic corticosteroids** can lead to **Cushing's syndrome**, **osteoporosis**, **diabetes**, and **hypertension**.

3. Scarring:

- Extensive mucosal erosions, particularly in the **oral cavity** or **genital areas**, may result in **scarring** and **strictures**.

4. Malnutrition and dehydration:

- Severe **oral erosions** may make **eating and drinking** difficult, leading to **malnutrition** and **weight loss**.

5. Relapse:

- Pemphigus vulgaris is a **chronic disease** that may relapse, especially if **immunosuppressive therapy** is tapered too quickly.

Summary of Key Points for Pemphigus Vulgaris:

- **Pemphigus vulgaris** is a chronic **autoimmune blistering disorder** affecting the **skin** and **mucous membranes**, caused by autoantibodies targeting **desmogleins**, leading to **loss of keratinocyte adhesion**.
- **Mucosal involvement** (e.g., **oral ulcers**) often precedes **flaccid blisters** on the skin. The condition is diagnosed by **clinical presentation**, **biopsy**, and **immunofluorescence testing**.
- **First-line treatment** includes **systemic corticosteroids** and **immunosuppressive agents** (e.g., **azathioprine**, **mycophenolate**), with **rituximab** becoming a preferred therapy due to its efficacy.
- Patients require **long-term monitoring** for **relapses** and **treatment-related side effects**, including complications from **immunosuppression** and **corticosteroids**.
- **Complications** include **secondary infections**, **corticosteroid-induced complications** (e.g., **diabetes**, **osteoporosis**), and **mucosal scarring**.

116. Bullous Pemphigoid

1. Detailed Definition of Bullous Pemphigoid:

Bullous pemphigoid (BP) is a chronic **autoimmune blistering disorder** characterized by the formation of **tense blisters** on the **skin**, particularly in the elderly. It results from

autoantibodies targeting **hemidesmosomes** in the **basement membrane** of the epidermis, specifically against **BP180** and **BP230 proteins**. This leads to a **subepidermal blistering** process, distinguishing it from **pemphigus vulgaris** (which has intraepidermal blistering). **BP** is generally less severe than pemphigus vulgaris and less likely to involve mucosal surfaces.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Tense bullae:**
 - Large, **tense blisters** filled with clear fluid, usually found on the **flexor surfaces** of the **arms, legs, abdomen, and groin**.
 - Blisters are **firm**, do not rupture easily, and are often surrounded by **erythema** (redness).
- **Itching (pruritus):**
 - **Severe itching** is often the first symptom and may precede the development of blisters by weeks or months.
- **Erosions:**
 - After the blisters rupture, they leave **shallow erosions** or **ulcers** with crusting.

b) Mucosal Involvement:

- **Rare** in bullous pemphigoid, although some patients may have mild involvement of the **oral mucosa**.

c) Systemic Symptoms:

- **Fatigue** and **malaise** may occur, particularly in older patients or in more widespread disease.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Look for **tense bullae** on **erythematous** skin, especially on the **trunk** and **extremities**.
 - Assess for any **mucosal involvement** and the presence of **erosions** after blisters rupture.

b) Skin Biopsy:

1. **Histopathology:**
 - Shows **subepidermal blisters** with **infiltration of eosinophils** in the blister cavity and surrounding tissues.
2. **Direct Immunofluorescence (DIF):**
 - Confirms diagnosis by demonstrating **linear deposition of IgG and C3** along the **basement membrane zone**.

c) Indirect Immunofluorescence or ELISA (for circulating autoantibodies):

- Detects circulating **anti-BP180** and **anti-BP230 autoantibodies**, which are responsible for the immune attack on the **basement membrane**.

d) Blood Tests:

1. **Complete blood count (CBC):**
 - To assess for signs of **infection** or **anaemia**, particularly if there are extensive erosions.
2. **Renal and liver function tests:**
 - Important to assess baseline organ function, especially if **systemic therapy** is being considered.

4. Explanation of Investigations:

- **Direct Immunofluorescence (DIF):** This is the gold standard for diagnosis. It shows a **linear pattern of IgG and C3 deposition** at the **dermoepidermal junction**, confirming the autoimmune nature of bullous pemphigoid.
- **Serum antibodies (ELISA):** Detection of circulating **anti-BP180** and **anti-BP230** antibodies helps confirm the diagnosis and can also be used to monitor disease activity.

5. Diagnosis Criteria for Bullous Pemphigoid:

Bullous pemphigoid is diagnosed based on:

1. **Clinical presentation:** Presence of **tense bullae** on erythematous skin, often with severe itching.
2. **Histopathology:** Shows **subepidermal blistering** with **eosinophilic infiltration**.
3. **Direct immunofluorescence:** Demonstrates **linear deposition of IgG and C3** along the basement membrane.
4. **Serological tests:** Detection of **anti-BP180 and anti-BP230 autoantibodies** via **ELISA** or **indirect immunofluorescence**.

6. First-Line Therapy According to Guidelines:

a) Topical Therapy:

1. **Topical corticosteroids:**
 - **Clobetasol propionate** (potent steroid) is often the first-line treatment in localized or mild cases.
 - **Mechanism:** Reduces local inflammation and autoantibody activity.

b) Systemic Corticosteroids:

1. **Prednisolone:**
 - Dosage: **0.5-1 mg/kg/day**, with gradual tapering once control is achieved.
 - **Mechanism:** Suppresses the immune system and reduces inflammation by inhibiting the formation of **blisters**.

c) Immunosuppressive Agents:

1. **Azathioprine or Mycophenolate mofetil:**
 - Used as **steroid-sparing agents** to maintain disease control and reduce the long-term side effects of corticosteroids.
 - **Mechanism:** Inhibits the proliferation of lymphocytes, which play a role in the production of autoantibodies.
2. **Methotrexate:**
 - An alternative for patients who are not tolerant to or do not respond to azathioprine.
 - **Mechanism:** Inhibits cell proliferation, reducing the immune response that leads to blister formation.

d) Biologic Therapy:

1. **Rituximab:**
 - A monoclonal antibody that targets **CD20-positive B cells**, reducing the production of autoantibodies in severe or refractory cases.
 - **Mechanism:** Depletes B cells, preventing the immune-mediated destruction of the skin's basement membrane.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Systemic corticosteroids** can cause significant **side effects** (e.g., **diabetes, osteoporosis, hypertension**), especially in elderly patients. Therefore, **steroid-sparing agents** are recommended for long-term management.

b) Second-Line Therapy:

1. Dapsone:

- May be considered in mild to moderate cases of bullous pemphigoid or as an adjunct to other therapies.
- **Mechanism:** Has anti-inflammatory effects and may reduce neutrophil migration into the skin.

2. Intravenous immunoglobulin (IVIG):

- For **refractory cases** where conventional therapies fail.
- **Mechanism:** Modulates the immune response by providing passive immunity and inhibiting autoantibody production.

8. Routine Monitoring and Follow-Up:

- **Regular blood tests:** Monitor **CBC, renal function, and liver function** to detect treatment-related side effects, especially in patients receiving **immunosuppressive therapy**.
- **Serum autoantibody levels:** Can be monitored to assess disease activity and guide tapering of therapy.
- **Bone density monitoring:** For patients on **long-term corticosteroids**, **DEXA scans** should be performed to assess for **osteoporosis**.

9. Complications:

1. Secondary infections:

- Open blisters and erosions are prone to **bacterial infections**, which can lead to **cellulitis** or **sepsis**.

2. Corticosteroid-related complications:

- Prolonged use of systemic corticosteroids may cause **Cushing's syndrome, diabetes, osteoporosis, and increased risk of infections**.

3. Recurrence:

- Bullous pemphigoid may relapse, especially if immunosuppressive therapy is tapered too quickly.

4. Erosions and scarring:

- While **scarring** is uncommon in BP, **post-inflammatory hyperpigmentation** or **erosions** may persist after the blisters resolve.

5. Malnutrition:

- Extensive **mucosal erosions** in rare cases can lead to **difficulty eating**, contributing to **weight loss** and **malnutrition**.

Summary of Key Points for Bullous Pemphigoid:

- **Bullous pemphigoid** is an **autoimmune blistering disorder** that primarily affects the **elderly** and presents with **tense blisters** on the skin, often accompanied by **severe itching**.
- Diagnosis is confirmed by **direct immunofluorescence**, which shows **linear IgG and C3 deposits** along the **basement membrane**.

- **First-line treatment** includes **topical or systemic corticosteroids** and **immunosuppressive agents** (e.g., **azathioprine** or **mycophenolate**), with **rituximab** reserved for severe or refractory cases.
- Patients require **long-term monitoring** for side effects of therapy and potential **relapses**.

117. Rosacea

1. Detailed Definition of Rosacea:

Rosacea is a common chronic inflammatory skin condition primarily affecting the **central face** (cheeks, nose, chin, and forehead). It is characterized by **facial flushing**, persistent **erythema**, **papules**, **pustules**, and in some cases, the development of **telangiectasia** (visible blood vessels) and **phymatous changes** (thickened, irregular skin, particularly on the nose). The exact cause of rosacea is unknown, but it is believed to involve a combination of **genetic predisposition**, **vascular dysregulation**, and **immune system dysfunction**. It typically occurs in **adults** aged **30-50 years**, with a higher prevalence in **fair-skinned individuals**.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Facial flushing:**
 - Persistent or episodic **redness**, often triggered by **heat**, **sunlight**, **spicy foods**, **alcohol**, **stress**, or **hot beverages**.
- **Persistent erythema:**
 - Redness that does not resolve, often confined to the **central face** (cheeks, nose, chin, forehead).
- **Papules and pustules:**
 - **Small red bumps** and **pustules** that resemble **acne**, although rosacea lacks the **comedones** (blackheads and whiteheads) typical of acne.
- **Telangiectasia:**
 - Prominent **visible blood vessels** on the surface of the skin, especially on the **cheeks** and **nose**.
- **Phymatous changes:**
 - **Thickened skin** and **irregular texture**, most commonly on the **nose** (**rhinophyma**), but also seen on the **chin** and **forehead** in severe cases.

b) Ocular Symptoms (Ocular Rosacea):

- **Dry, irritated, or bloodshot eyes.**
- **Grittiness** or **burning sensation** in the eyes.
- In severe cases, rosacea can cause **blepharitis** (eyelid inflammation) and **conjunctivitis**.

c) Systemic Symptoms:

- Typically, rosacea does not cause **systemic symptoms** but can be psychologically distressing due to its cosmetic impact.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Examine the **central face** for **persistent erythema**, **papules**, **pustules**, and **telangiectasia**.

- Assess the **nose, cheeks, forehead, and chin** for signs of **rhinophyma** or **thickened skin**.

b) Diagnostic Tests:

- **Diagnosis of exclusion:** Rosacea is typically diagnosed clinically based on the characteristic symptoms. No specific diagnostic tests are required unless there is a suspicion of other conditions like **lupus** or **seborrheic dermatitis**.

c) Rule out other causes:

1. **Skin biopsy** (rarely done):
 - May be performed if there is doubt about the diagnosis or if another condition is suspected, such as **lupus erythematosus** or **sarcoidosis**.

4. Explanation of Investigations:

- **Clinical diagnosis:** Rosacea is primarily diagnosed based on the **typical pattern** of facial involvement and the presence of **flushing, papules, and telangiectasia**.
- **Exclusion of other conditions:** Conditions such as **acne, seborrheic dermatitis, or lupus** may mimic rosacea and should be ruled out through clinical examination and, if needed, **biopsy or blood tests** (e.g., **ANA** for lupus).

5. Diagnosis Criteria for Rosacea:

Diagnosis is made based on the presence of **one or more** of the following:

1. **Facial flushing** or persistent **central facial erythema**.
2. **Papules and pustules** that resemble acne, but without **comedones**.
3. **Telangiectasia** (visible blood vessels).
4. **Phymatous changes** (thickened skin, most commonly on the nose).

Additionally, patients may present with **ocular involvement**, such as **dry eyes, red eyes, or conjunctivitis**.

6. First-Line Therapy According to Guidelines:

a) General Measures:

1. **Trigger avoidance:**
 - Educate patients to **avoid known triggers** such as **alcohol, spicy foods, extreme temperatures, sunlight, and stress**.
2. **Sun protection:**
 - Daily use of **broad-spectrum sunscreen** (SPF 30 or higher) to reduce exacerbation from UV light.

b) Topical Therapy:

1. **Topical metronidazole:**
 - Dosage: Apply **twice daily**.
 - **Mechanism:** Has **anti-inflammatory** and **antimicrobial** effects, reducing **papules and pustules**.
2. **Topical azelaic acid:**
 - Dosage: Apply **twice daily**.
 - **Mechanism:** Reduces **inflammation** and **papules**, improves **skin texture**, and decreases **redness**.
3. **Brimonidine gel:**
 - **Mechanism:** **Vasoconstrictor** that reduces **erythema** by narrowing blood vessels.

c) Oral Therapy:

1. **Oral tetracyclines** (e.g., **doxycycline** or **minocycline**):
 - Dosage: **40-100 mg daily**, typically for **moderate to severe** cases or in patients with **ocular involvement**.
 - **Mechanism**: Reduces **inflammation** and **papules** and has **anti-microbial** properties.
2. **Isotretinoin**:
 - Used in **refractory cases** of rosacea, especially when **papules**, **pustules**, and **phymatous changes** are predominant.
 - **Mechanism**: Reduces **sebum production**, shrinks **sebaceous glands**, and decreases **inflammation**.

7. Contraindications and Second-Line Therapy:

a) Contraindications:

- **Topical metronidazole** or **azelaic acid** may cause **skin irritation** in sensitive individuals. If **irritation** or **contact dermatitis** occurs, consider switching to an **alternative agent**.
- **Oral tetracyclines** should be used with caution in patients with **liver disease**, **pregnancy**, or **children under 8 years**.

b) Second-Line Therapy:

1. **Laser therapy**:
 - **Pulsed dye laser** or **intense pulsed light (IPL)** may be used to target **telangiectasia** and **persistent erythema**.
 - **Mechanism**: Destroys **dilated blood vessels**, reducing visible redness.
2. **Surgical therapy** (for **phymatous rosacea**):
 - **Laser ablation**, **dermabrasion**, or **electrosurgery** may be used to remove **thickened skin** in cases of **rhinophyma** or other phymatous changes.

8. Routine Monitoring and Follow-Up:

- **Symptom monitoring**: Regular follow-up to assess for **improvement of symptoms** (flushing, papules, erythema) and ensure **treatment adherence**.
- **Ocular involvement**: For patients with **ocular rosacea**, refer to an **ophthalmologist** for specialized care if symptoms worsen.

9. Complications:

1. **Ocular rosacea**:
 - Can lead to **keratitis**, **conjunctivitis**, or **blepharitis**, potentially affecting **vision** if left untreated.
2. **Phymatous changes**:
 - Severe **thickening of the skin**, particularly **rhinophyma**, can be **disfiguring** and may require **surgical intervention**.
3. **Psychological impact**:
 - Rosacea can lead to **low self-esteem**, **social anxiety**, and **depression** due to its **cosmetic effects**.

Summary of Key Points for Rosacea:

- **Rosacea** is a chronic inflammatory condition affecting the **central face**, characterized by **facial flushing**, **erythema**, **papules**, **pustules**, and **telangiectasia**.

- **Diagnosis** is clinical and based on **facial distribution** and the presence of **papules** and **telangiectasia** without comedones.
- **First-line treatment** includes **topical metronidazole**, **azelaic acid**, and **oral tetracyclines** for more severe cases.
- **Trigger avoidance** and **sun protection** are important for long-term management.
- **Complications** include **ocular involvement**, **phymatous changes**, and **psychological impact**, with **laser therapy** and **surgical interventions** reserved for severe cases.

118. Psoriasis

1. Detailed Definition of Psoriasis:

Psoriasis is a chronic, immune-mediated inflammatory skin disease characterized by the development of **scaly, erythematous plaques** primarily on the **extensor surfaces** of the body (such as the elbows, knees, and scalp). The disease is driven by **dysregulated immune activity**, specifically involving **T-cells** and an overproduction of **pro-inflammatory cytokines** such as **TNF- α** , **IL-17**, and **IL-23**, leading to hyperproliferation of keratinocytes. Psoriasis can range from mild to severe and is often associated with **systemic comorbidities** such as **psoriatic arthritis**, **cardiovascular disease**, and **metabolic syndrome**.

2. Common Presenting Complaints and Symptoms:

a) Skin Symptoms:

- **Plaques:**
 - **Well-demarcated, red plaques** covered with **silvery-white scales**, most commonly on the **elbows, knees, scalp**, and **lower back**.
- **Auspitz sign:**
 - **Pinpoint bleeding** seen when the **scale** is removed from the plaque.
- **Koebner phenomenon:**
 - Development of new psoriatic plaques in areas of **trauma** or **injury** to the skin (e.g., cuts, scratches, or sunburn).
- **Nail changes:**
 - **Pitting, onycholysis** (separation of the nail from the nail bed), **thickening**, and **discoloration** of the nails are common in **nail psoriasis**.

b) Types of Psoriasis:

1. **Plaque psoriasis (psoriasis vulgaris):**
 - The most common form, with large, well-defined plaques.
2. **Guttate psoriasis:**
 - Characterized by **small, drop-like lesions**, typically triggered by a **streptococcal infection**.
3. **Inverse psoriasis:**
 - Affects **intertriginous areas** (e.g., armpits, groin, under the breasts), presenting as **smooth, red patches** without the typical scale.
4. **Pustular psoriasis:**
 - Presents with **sterile pustules** on an erythematous background and can be localized (palms and soles) or generalized (more severe).
5. **Erythrodermic psoriasis:**
 - A rare, severe form characterized by **widespread erythema** and **desquamation** covering most of the body. This type requires urgent medical attention due to the risk of **infection** and **systemic complications**.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Look for **scaly plaques** on **extensor surfaces** (elbows, knees, scalp) and assess for **Auspitz sign** and **Koebner phenomenon**.
 - Examine the **nails** for **pitting**, **onycholysis**, and **thickening**.

b) Blood Tests:

1. **Inflammatory markers:**
 - **C-reactive protein (CRP)** and **erythrocyte sedimentation rate (ESR)** may be elevated, especially in **psoriatic arthritis**.
2. **Liver function tests:**
 - Monitor for liver function if considering **systemic therapies** like **methotrexate**.

c) Skin Biopsy (in unclear cases):

- A **skin biopsy** may be performed to confirm the diagnosis if clinical features are atypical. Histology reveals **hyperkeratosis**, **parakeratosis**, **acanthosis**, and **neutrophil microabscesses** in the stratum corneum (Munro's microabscesses).

4. Explanation of Investigations:

- **Clinical diagnosis:** Psoriasis is primarily diagnosed based on its **clinical presentation** of well-demarcated **scaly plaques** on extensor surfaces and typical nail changes. A **biopsy** is rarely necessary unless the diagnosis is uncertain.
- **Inflammatory markers:** May be used to assess for systemic involvement, particularly in **psoriatic arthritis**.

5. Diagnosis Criteria for Psoriasis:

The diagnosis of **psoriasis** is typically made clinically based on:

1. **Characteristic plaques:** Well-demarcated **scaly plaques** on **extensor surfaces**, scalp, or lower back.
2. **Auspitz sign:** Pinpoint bleeding when the **scale** is removed.
3. **Nail changes:** **Pitting**, **thickening**, and **onycholysis**.
4. **Koebner phenomenon:** Appearance of lesions following **skin trauma**.

6. First-Line Therapy According to Guidelines:

a) Topical Therapy:

1. **Topical corticosteroids:**
 - **Potent corticosteroids** (e.g., **clobetasol propionate**) are commonly used to reduce **inflammation** and **plaque thickness**.
 - **Mechanism:** Reduces local **inflammation** and suppresses the hyperproliferative skin response.
2. **Topical vitamin D analogs** (e.g., **calcipotriol**):
 - **Mechanism:** Inhibits **keratinocyte proliferation** and promotes normal differentiation of skin cells.
3. **Coal tar preparations:**
 - Used for **mild to moderate** psoriasis, particularly for **scalp psoriasis**.
 - **Mechanism:** Reduces **scaling** and **inflammation**.

b) Phototherapy:

1. **Narrowband UVB phototherapy:**

- **Mechanism:** Slows down the growth of affected skin cells and reduces **inflammation**.
- Often used for **moderate to severe** psoriasis when topical treatments are insufficient.

c) Systemic Therapy:

1. **Methotrexate:**
 - Dosage: **7.5-25 mg** weekly.
 - **Mechanism:** Reduces **inflammation** by inhibiting **dihydrofolate reductase**, thus suppressing the immune response.
2. **Ciclosporin:**
 - Dosage: **2.5-5 mg/kg/day**.
 - **Mechanism:** Suppresses the immune system by inhibiting **T-cell activation**.
3. **Acitretin:**
 - A **retinoid** used for severe **pustular** or **erythrodermic psoriasis**.
 - **Mechanism:** Normalizes **keratinocyte differentiation** and reduces **inflammation**.

d) Biologic Therapy:

1. **TNF-alpha inhibitors** (e.g., **infliximab**, **adalimumab**):
 - **Mechanism:** Inhibits **TNF-α**, a key pro-inflammatory cytokine involved in psoriasis.
2. **IL-17 inhibitors** (e.g., **secukinumab**):
 - **Mechanism:** Blocks **IL-17**, reducing the inflammatory response in psoriasis.
3. **IL-23 inhibitors** (e.g., **guselkumab**):
 - **Mechanism:** Inhibits **IL-23**, a cytokine involved in **T-cell activation** and **inflammation**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Systemic therapies** like **methotrexate** are contraindicated in patients with **liver disease**, **alcohol abuse**, or **pregnancy** due to the risk of **hepatotoxicity** and **teratogenicity**.
- **Biologics** should be used cautiously in patients with a history of **recurrent infections** or **latent tuberculosis**.

b) Second-Line Therapy:

1. **Apremilast:**
 - **Mechanism:** Inhibits **phosphodiesterase-4 (PDE-4)**, leading to reduced production of pro-inflammatory cytokines.
 - Used in **moderate to severe psoriasis** when other systemic therapies are contraindicated or ineffective.
2. **Fumaric acid esters:**
 - Used in **moderate to severe plaque psoriasis** in some European countries.
 - **Mechanism:** Modulates immune response and reduces inflammation.

8. Routine Monitoring and Follow-Up:

- **Blood tests:** Regular monitoring of **liver function**, **renal function**, and **CBC** in patients on systemic therapies such as **methotrexate** or **ciclosporin**.
- **Tuberculosis screening:** Required before initiating **biologic therapy** to rule out **latent TB**.

- **Psoriatic arthritis monitoring:** Screen for symptoms of **joint pain** and **stiffness**, as early treatment of **psoriatic arthritis** can prevent joint damage.

9. Complications:

1. Psoriatic arthritis:

- A chronic inflammatory arthritis associated with psoriasis, affecting up to **30%** of patients. It can cause **joint pain**, **stiffness**, and **erosion** of bone if left untreated.

2. Cardiovascular disease:

- Psoriasis is associated with an increased risk of **heart disease**, **hypertension**, and **stroke**

3. Metabolic syndrome:

- Patients with psoriasis have a higher risk of developing **metabolic syndrome**, which includes conditions like **obesity**, **diabetes**, **hyperlipidemia**, and **hypertension**.

4. Psychological impact:

- Psoriasis can have significant psychological effects, leading to **anxiety**, **depression**, and **social isolation**, due to the visible and often chronic nature of the condition.

5. Infection:

- Both **psoriatic skin** (due to skin barrier disruption) and **immunosuppressive treatments** increase the risk of **secondary bacterial skin infections** and systemic infections.

6. Nail psoriasis:

- Nail involvement can lead to **dystrophy**, **pain**, and difficulty performing daily tasks. This can contribute to reduced quality of life, especially in patients with associated **psoriatic arthritis**.

10. Summary of Key Points for Psoriasis:

- **Psoriasis** is a chronic **immune-mediated inflammatory skin disease** characterized by **scaly, erythematous plaques** predominantly on the **extensor surfaces**.
- **Diagnosis** is primarily clinical, based on characteristic **plaque distribution**, **scaling**, and associated findings like **nail changes** and the **Koebner phenomenon**.
- **First-line treatments** include **topical corticosteroids** and **vitamin D analogs** for mild cases, **phototherapy** for moderate cases, and **systemic therapies** (e.g., **methotrexate**, **biologics**) for severe or refractory cases.
- **Regular follow-up** and **monitoring** of systemic involvement (e.g., **psoriatic arthritis**) and side effects of systemic therapies (e.g., **liver function** with methotrexate) are essential for long-term management.
- **Complications** include **psoriatic arthritis**, increased risk of **cardiovascular disease**, and **psychological impact**, making comprehensive care important in improving patient outcomes and quality of life.

119. Acne Vulgaris

1. Detailed Definition of Acne Vulgaris:

Acne vulgaris is a common chronic inflammatory skin condition affecting the **pilosebaceous units** (hair follicles and sebaceous glands). It is characterized by **comedones** (blackheads and whiteheads), **papules**, **pustules**, **nodules**, and sometimes **cysts**. Acne is most prevalent in

adolescents but can occur in adults. It primarily affects areas with a high density of sebaceous glands, such as the **face, chest, and back**. **Acne vulgaris** results from a combination of **increased sebum production, abnormal keratinocyte desquamation, bacterial proliferation** (particularly *Cutibacterium acnes*), and **inflammation**.

2. Common Presenting Complaints and Symptoms:

a) Skin Lesions:

- **Comedones:**
 - **Open comedones** (blackheads): Small **dilated hair follicles** filled with **oxidized keratin** and **sebum**.
 - **Closed comedones** (whiteheads): Small **flesh-coloured** papules that occur when a hair follicle becomes plugged with **sebum** and **dead skin cells**.
- **Inflammatory lesions:**
 - **Papules:** Small, red, inflamed bumps.
 - **Pustules:** Red bumps with a **white center** containing **pus**.
- **Severe lesions:**
 - **Nodules:** Large, solid, painful lesions that extend into the deeper layers of the skin.
 - **Cysts:** Deep, painful, pus-filled lesions that may lead to **scarring**.

b) Distribution:

- **Face, back, chest, and shoulders** are most commonly affected due to a higher concentration of **sebaceous glands**.

c) Psychological Symptoms:

- Acne can cause **psychological distress**, including **low self-esteem, anxiety, and depression**, particularly in adolescents.

3. First-Line Investigations:

a) Clinical Examination:

- **Visual inspection:**
 - Assess for the presence of **comedones, inflammatory papules, pustules, nodules, and cysts**.
 - Examine the **distribution** of lesions (face, back, chest).

b) Blood Tests (rarely needed):

- In cases of suspected **endocrine disorders**, such as **polycystic ovary syndrome (PCOS)**, blood tests may be performed to check **androgen levels**.
- **Hormonal assays:**
 - **Testosterone, DHEAS, LH/FSH ratio** (in cases of suspected **hormonal acne**).

4. Explanation of Investigations:

- **Clinical diagnosis:** Acne is typically diagnosed based on the **clinical appearance** of the skin lesions, including **comedones, inflammatory papules, and nodules**.
- **Hormonal evaluation:** In cases of **adult female acne** or signs of **hyperandrogenism** (e.g., **hirsutism, irregular periods**), **androgen levels** and **hormonal tests** may be indicated.

5. Diagnosis Criteria for Acne Vulgaris:

Acne vulgaris is diagnosed clinically based on the presence of **comedones, inflammatory papules**, and/or **nodules**, particularly in areas rich in sebaceous glands such as the **face, chest, and back**.

Severity classification:

1. **Mild acne:** Comedones with a few papules or pustules.
2. **Moderate acne:** More numerous papules and pustules with mild scarring.
3. **Severe acne:** Extensive papules, pustules, nodules, or cysts, often associated with scarring.

6. First-Line Therapy According to Guidelines:

a) Topical Therapy:

1. **Topical retinoids** (e.g., **adapalene, tretinoin**):
 - **Mechanism:** Normalize keratinocyte desquamation, preventing the formation of **comedones**.
 - Used as first-line therapy for **mild to moderate acne**.
2. **Topical benzoyl peroxide:**
 - **Mechanism:** Kills *Cutibacterium acnes* and reduces inflammation.
 - Available as a **5% gel or wash** and is often used in combination with other treatments.
3. **Topical antibiotics** (e.g., **clindamycin, erythromycin**):
 - **Mechanism:** Reduces bacterial load and inflammation.
 - **Combination therapy** with benzoyl peroxide is recommended to prevent the development of **antibiotic resistance**.

b) Oral Therapy:

1. **Oral antibiotics** (e.g., **doxycycline, minocycline**):
 - Used for **moderate to severe inflammatory acne**.
 - **Mechanism:** Reduces *C. acnes* and has anti-inflammatory properties.
 - Typically used for **6-12 weeks**, often combined with **topical treatments**.
2. **Oral contraceptives** (for females with hormonal acne):
 - **Mechanism:** Reduces androgen production, decreasing sebum production and improving acne.
 - Commonly used options include **ethinyl estradiol** combined with **norgestimate** or **drospirenone**.
3. **Spironolactone:**
 - **Mechanism:** Acts as an **androgen receptor antagonist**, reducing the effects of androgens on sebaceous glands.
 - Commonly used in females with **hormonal acne**.
4. **Oral isotretinoin:**
 - Used for **severe cystic acne** or acne resistant to other treatments.
 - **Mechanism:** Reduces sebum production, decreases *C. acnes* proliferation, and normalizes keratinocyte turnover.
 - **Dosage:** Typically **0.5-1 mg/kg/day** for **4-6 months**.
 - Requires **regular monitoring** due to potential side effects, including **teratogenicity, elevated liver enzymes, and lipid abnormalities**.

7. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- **Oral isotretinoin** is **teratogenic** and contraindicated in **pregnancy**. Women must use **effective contraception** during treatment.
- **Oral antibiotics** should be avoided for long-term use due to the risk of **antibiotic resistance**.
- **Spironolactone** is contraindicated in **pregnancy** and requires monitoring for **hyperkalemia**.

b) Second-Line Therapy:

1. **Laser therapy:**
 - Used for **acne scars** and **persistent redness** after acne clears.
 - **Mechanism:** Promotes **collagen remodeling** and reduces **inflammation**.
2. **Chemical peels:**
 - May be used for **superficial acne** and **post-inflammatory hyperpigmentation**.

8. Routine Monitoring and Follow-Up:

- **Monthly follow-ups** to assess treatment efficacy and monitor for side effects, especially in patients on **isotretinoin** or **oral antibiotics**.
- **Hormonal evaluation** may be repeated in females with persistent or refractory acne, especially those with suspected **PCOS**.
- **Liver function tests** and **lipid panels** are recommended every **4-8 weeks** for patients on **isotretinoin**.

9. Complications:

1. **Scarring:**
 - Acne can lead to **permanent scars**, especially if the condition is not treated early or is severe (nodular or cystic acne).
2. **Post-inflammatory hyperpigmentation (PIH):**
 - Dark spots can remain after acne lesions heal, particularly in individuals with **darker skin tones**.
3. **Psychological impact:**
 - **Anxiety, depression, and low self-esteem** are common in patients with severe or long-standing acne.
4. **Antibiotic resistance:**
 - Long-term use of **topical** or **oral antibiotics** can lead to **resistant strains** of *C. acnes*.
5. **Side effects of isotretinoin:**
 - **Teratogenicity, dry skin, liver toxicity, and mood changes**.

Summary of Key Points for Acne Vulgaris:

- **Acne vulgaris** is a common chronic skin condition characterized by **comedones, papules, pustules**, and sometimes **nodules** or **cysts**.
- **Diagnosis** is clinical, and treatment is based on the **severity** of the acne. **Topical therapies** (e.g., **retinoids, benzoyl peroxide**) are used for **mild to moderate** cases, while **oral therapies** (e.g., **antibiotics, isotretinoin**) are reserved for **moderate to severe** acne.

Endocrine

120. Type 1 Diabetes Mellitus

1. Detailed Definition of Type 1 Diabetes Mellitus (T1DM):

Type 1 diabetes mellitus is a chronic autoimmune condition where the body's immune system attacks and destroys the insulin-producing **beta cells** in the **pancreas**, leading to **absolute insulin deficiency**. As a result, blood glucose levels rise, and insulin therapy is required for life. This form of diabetes typically presents in **childhood** or **young adulthood**, although it can occur at any age. The precise cause is multifactorial, involving **genetic predisposition** and **environmental triggers** (e.g., viral infections).

2. Common Presenting Complaints and Symptoms:

- **Polyuria**: Increased urination due to osmotic diuresis.
- **Polydipsia**: Excessive thirst as a result of dehydration.
- **Polyphagia**: Increased hunger due to energy depletion from lack of insulin.
- **Weight loss**: Despite normal or increased appetite, the body is unable to use glucose for energy.
- **Fatigue**: Due to the body's inability to utilise glucose efficiently.
- **Blurred vision**: Osmotic changes in the lens can cause visual disturbances.
- **Recurrent infections**: Increased glucose in body fluids can lead to infections like **thrush** or **urinary tract infections**.

Diabetic ketoacidosis (DKA), a serious complication, may occur at diagnosis and includes:

- **Abdominal pain**
- **Nausea and vomiting**
- **Dehydration and dry mouth**
- **Kussmaul breathing** (deep, laboured breathing)
- **Fruity, acetone-like breath** (smells like pear drops)

3. First-Line Investigations:

a) Blood Glucose Testing:

1. **Random plasma glucose**:
 - A reading of ≥ 11.1 mmol/L with symptoms is diagnostic.
2. **Fasting plasma glucose**:
 - A fasting level of ≥ 7.0 mmol/L confirms the diagnosis.

b) HbA1c (Glycated Haemoglobin):

- Although typically used for **Type 2 diabetes**, it's less useful in acute-onset **Type 1 diabetes** as it reflects glucose levels over the previous 2-3 months. An **HbA1c ≥ 48 mmol/mol (6.5%)** suggests diabetes but may not capture rapid changes seen in T1DM.

c) Ketone Testing:

1. **Urine dipstick**:
 - Detects **glucose** and **ketones**, which indicate possible **DKA**.
2. **Blood ketones**:
 - **Serum ketones ≥ 3 mmol/L** strongly suggest **DKA**.

d) C-peptide:

- This measures **endogenous insulin production**. Low levels are typical in T1DM, reflecting the destruction of **beta cells**.

e) Autoantibodies:

1. **Glutamic acid decarboxylase antibodies (GAD):** Positive in ~80% of T1DM cases.
2. **Islet cell antibodies (ICA):** Found in 70-80% of patients.
3. **Insulin autoantibodies (IAA):** Common in younger patients.
4. **Insulinoma-associated-2 autoantibodies (IA-2A):** Found in some patients with T1DM.

4. Explanation of Investigations:

- **Glucose measurements** (random and fasting) provide a direct indicator of **hyperglycaemia**, which is diagnostic when levels exceed set thresholds.
- **HbA1c** is helpful for chronic glucose monitoring but not ideal for diagnosing rapid-onset Type 1 diabetes.
- **Ketone testing** (blood or urine) is critical for diagnosing **DKA**.
- **C-peptide** helps confirm the degree of insulin deficiency.
- **Autoantibodies** differentiate between Type 1 and Type 2 diabetes by indicating an autoimmune process.

5. Diagnostic Criteria for Type 1 Diabetes Mellitus:

Diagnosis is confirmed by the following:

1. **Fasting glucose ≥ 7.0 mmol/L** or **random glucose ≥ 11.1 mmol/L**.
2. **If the patient is asymptomatic**, these criteria must be met on **two separate occasions**.
3. **Ketosis** and **weight loss** are typical presenting features in T1DM.
4. The presence of **autoantibodies** (e.g., GAD, ICA) supports the diagnosis.

6. Distinguishing Type 1 from Type 2 Diabetes Mellitus:

Feature	Type 1 Diabetes	Type 2 Diabetes
Age of onset	Typically < 20 years (but can occur >30 years)	Typically >40 years (but can occur in younger obese patients)
Speed of onset	Acute (hours to days)	Gradual (weeks to months)
Weight of patient	Recent weight loss typical	Obesity is common
Features	DKA common	Milder symptoms (e.g., polyuria, polydipsia)
Ketonuria	Common	Rare

7. First-Line Therapy According to Guidelines:

a) Insulin Therapy:

1. **Multiple daily injections (MDI):**
 - **Basal-bolus regimen:** Long-acting insulin (e.g., **insulin glargine**) combined with short-acting insulin (e.g., **insulin lispro**) before meals.
 - **Mechanism:** Mimics natural insulin release by providing basal and bolus doses based on carbohydrate intake.
2. **Continuous subcutaneous insulin infusion (CSII)** (insulin pump therapy):
 - Recommended for patients unable to achieve glucose control on MDI.

b) Blood Glucose Monitoring:

- **Self-monitoring** of blood glucose is essential, with at least **4 daily tests** (before meals and at bedtime).

- **Target glucose levels:**
 - Fasting: **5-7 mmol/L**.
 - Before meals: **4-7 mmol/L**.

c) Dietary and Lifestyle Advice:

- **Carbohydrate counting:** Helps adjust insulin doses based on carbohydrate intake.
- **Healthy eating:** A balanced diet with regular meal timings is essential.

8. Contraindications and Second-Line Therapy:

a) Contraindications to First-Line Therapy:

- Insulin therapy is **essential** for all patients with Type 1 diabetes. However, the type of insulin may vary based on patient needs.
- **Metformin:** May be added in **overweight patients** with T1DM who have insulin resistance, but it's not a substitute for insulin.

b) Second-Line Therapy:

1. **Adjunctive therapies:**
 - **Pramlintide:** An amylin analog used to control post-meal blood sugar levels.
2. **Continuous glucose monitoring (CGM):**
 - Provides real-time glucose readings and helps adjust insulin doses.

9. Routine Monitoring and Follow-Up:

1. **HbA1c:**
 - Measured every **3-6 months** with a target of **≤48 mmol/mol (6.5%)** to assess long-term glucose control.
2. **Screening for complications:**
 - **Retinopathy:** Annual retinal screening.
 - **Nephropathy:** Annual urine **albumin-creatinine ratio** and **serum creatinine**.
 - **Neuropathy:** Regular foot checks for nerve damage.
3. **Blood Pressure and Lipid Monitoring:**
 - Blood pressure should be monitored annually, with target **<140/80 mmHg**.
 - Statins are recommended for patients over **40 years** or younger if there is an increased cardiovascular risk.

10. Complications:

1. **Diabetic ketoacidosis (DKA):**
 - A life-threatening complication requiring urgent treatment with insulin and fluids.
2. **Hypoglycaemia:**
 - Results from overuse of insulin or missed meals, leading to **low blood sugar**.
3. **Microvascular complications:**
 - **Retinopathy, nephropathy, and neuropathy** are more common due to chronically elevated blood sugars.
4. **Macrovascular complications:**
 - Increased risk of **heart disease, stroke, and peripheral vascular disease**.

Summary of Key Points for Type 1 Diabetes Mellitus:

- **Type 1 diabetes** is an autoimmune condition that causes **insulin deficiency**, resulting in **hyperglycaemia**.

- **Diagnosis** involves fasting/random glucose levels, **ketosis**, and the presence of **autoantibodies**.
- **Insulin therapy** is the cornerstone of treatment, with **self-monitoring of blood glucose** essential for day-to-day management.
- Long-term complications include both **microvascular** and **macrovascular** diseases, requiring **regular monitoring** and follow-up.

121. Type 2 Diabetes Mellitus

1. Detailed Definition of Type 2 Diabetes Mellitus (T2DM):

Type 2 diabetes mellitus (T2DM) is a chronic metabolic condition characterised by **insulin resistance** and **relative insulin deficiency**, leading to elevated blood glucose levels (**hyperglycaemia**). Unlike Type 1 diabetes, which is caused by autoimmune destruction of pancreatic beta cells, T2DM typically develops due to **genetic predisposition**, **obesity**, and **lifestyle factors**. It is most common in adults over **40 years**, but increasing obesity rates have led to earlier onset, including in adolescents.

2. Common Presenting Complaints and Symptoms:

- **Polyuria**: Frequent urination due to osmotic diuresis.
- **Polydipsia**: Excessive thirst resulting from dehydration.
- **Fatigue**: General tiredness due to the inefficient use of glucose by the cells.
- **Blurred vision**: Caused by osmotic changes in the lens due to high blood glucose levels.
- **Recurrent infections**: Such as **urinary tract infections (UTIs)**, **genital candidiasis**, or **skin infections** caused by elevated blood glucose, which creates a favourable environment for pathogens.
- **Weight loss**: Less common in Type 2 diabetes but may occur in late-stage disease.

Patients with Type 2 diabetes may be diagnosed incidentally during routine screening, often in the context of **hypertension**, **hyperlipidaemia**, or **cardiovascular disease**.

3. First-Line Investigations:

a) Blood Glucose Testing:

1. **Fasting plasma glucose**:
 - A level ≥ 7.0 mmol/L is diagnostic of diabetes.
2. **Random plasma glucose**:
 - A level ≥ 11.1 mmol/L confirms diabetes.

b) HbA1c (Glycated Haemoglobin):

- Measures average blood glucose over the preceding **2-3 months**.
- ≥ 48 mmol/mol (**6.5%**) is diagnostic of diabetes.

c) Oral Glucose Tolerance Test (OGTT):

- 2-hour plasma glucose level ≥ 11.1 mmol/L after a 75g glucose load indicates diabetes.

d) Urine Testing:

- **Urine dipstick**: May show glucose or protein, indicating diabetes-related kidney issues.

e) Lipid Profile:

- Evaluate **cholesterol**, **LDL**, **HDL**, and **triglycerides** to assess cardiovascular risk.

4. Explanation of Investigations:

- **Blood glucose testing**: Directly measures plasma glucose levels and provides a quick diagnosis.

- **HbA1c:** Reflects **long-term glycaemic control**, useful for monitoring disease progression and management.
- **OGTT:** Useful in patients with borderline fasting glucose for confirmation.
- **Urine dipstick:** Detects **glucose** or **proteinuria**, suggesting **diabetic nephropathy**.

5. Diagnosis Criteria for Type 2 Diabetes Mellitus:

T2DM is diagnosed when:

1. **Fasting plasma glucose** ≥ 7.0 mmol/L, or
2. **Random plasma glucose** ≥ 11.1 mmol/L, or
3. **HbA1c** ≥ 48 mmol/mol (6.5%), or
4. **OGTT 2-hour glucose** ≥ 11.1 mmol/L.

For asymptomatic patients, these thresholds must be confirmed on **two separate occasions**.

6. First-Line Therapy According to NICE 2022 Guidelines:

a) Lifestyle Modification:

1. **Dietary changes:**
 - **High-fibre, low glycaemic index carbohydrates.**
 - **Low-fat dairy** and **oily fish** should be included.
 - Reduce **saturated fats** and **trans fatty acids**.
 - Limit **sucrose-containing foods**, avoiding excess calorie intake.
 - Discourage foods marketed specifically for people with diabetes.
 - Initial weight loss goal: **5-10% of body weight**.
2. **Exercise:**
 - **150 minutes** of moderate aerobic activity weekly (e.g., brisk walking).
 - Strength training exercises at least **twice a week**.
3. **Weight loss:**
 - Achieving a healthy **BMI** is crucial for reducing insulin resistance.

b) Pharmacological Therapy:

1. **First-line: Metformin:**
 - Dosage: **500 mg once daily**, titrated up to **2,000 mg daily**.
 - **Mechanism:** Reduces **hepatic glucose production** and increases **insulin sensitivity** in tissues.
 - Metformin is the first-line drug for most patients unless contraindicated.
2. **SGLT-2 Inhibitors** (e.g., **empagliflozin**) in addition to metformin if:
 - High cardiovascular risk (QRISK $\geq 10\%$).
 - Established cardiovascular disease (CVD) or chronic heart failure.
 - **Mechanism:** Promotes **glucose excretion** via urine, lowering blood glucose levels.
 - Introduced when HbA1c rises to **≥ 58 mmol/mol (7.5%)** despite metformin.
3. **Alternative to metformin** (if contraindicated):
 - **DPP-4 inhibitors** (e.g., **sitagliptin**), **pioglitazone**, or **sulfonylureas** can be considered.

7. HbA1c Targets and Monitoring:

HbA1c Targets:

- **Lifestyle intervention alone** or **metformin:** Target **48 mmol/mol (6.5%)**.
- **With sulfonylureas** or drugs causing hypoglycaemia: Target **53 mmol/mol (7.0%)**.

Monitoring:

- **Check HbA1c every 3-6 months** until stable, then every 6 months.
- Relax HbA1c targets in older or frail individuals or those with significant comorbidities.

8. Further Drug Therapy if HbA1c Targets Are Not Met:

Second-Line Therapy:

When HbA1c rises to **58 mmol/mol (7.5%)**, consider **dual therapy**:

1. **Metformin + DPP-4 inhibitor.**
2. **Metformin + pioglitazone.**
3. **Metformin + sulfonylurea.**
4. **Metformin + SGLT-2 inhibitor** (if criteria met).

Third-Line Therapy:

If dual therapy is insufficient, introduce **triple therapy**:

1. **Metformin + DPP-4 inhibitor + sulfonylurea.**
2. **Metformin + pioglitazone + sulfonylurea.**
3. **Insulin therapy:** If oral agents fail, start with **basal insulin**.

GLP-1 Agonists (e.g., Liraglutide):

Considered if BMI ≥ 35 kg/m² or if insulin therapy is unsuitable due to occupational reasons or other comorbidities. Continue only if there is a **$\geq 1\%$ reduction in HbA1c** and **$\geq 3\%$ weight loss** within 6 months.

9. Risk Factor Modification:

Hypertension:

- BP targets:
 - **<140/90 mmHg** for those <80 years.
 - **<150/90 mmHg** for those ≥ 80 years.
- First-line agents: **ACE inhibitors** or **angiotensin II receptor blockers (ARBs)**.

Antiplatelets:

- Antiplatelet therapy (e.g., aspirin) is recommended only for patients with **existing cardiovascular disease**.

Lipid Management:

- Patients with a **QRISK score >10%** should be started on **atorvastatin 20 mg** to reduce cardiovascular risk.

10. Routine Monitoring and Follow-Up:

1. **HbA1c:**
 - Measured every **3-6 months**. Target: **48-53 mmol/mol** depending on therapy.
2. **Blood pressure:**
 - Regular monitoring with targets of **<140/90 mmHg** for younger patients and **<150/90 mmHg** for older adults.
3. **Lipid profile:**
 - Yearly check for lipid levels, and statin therapy if indicated by cardiovascular risk.
4. **Kidney function:**
 - Annual checks for **urinary albumin ratio** and **eGFR** to monitor for diabetic nephropathy.
5. **Retinopathy screening:**
 - Annual screening to detect early **diabetic retinopathy**.
6. **Foot checks:**

- Regular screening for **neuropathy** and the risk of **diabetic foot ulcers**.

Summary of Key Points for Type 2 Diabetes Mellitus:

- **T2DM** is characterised by **insulin resistance** and **relative insulin deficiency**.
- Diagnosis is based on **blood glucose**, **HbA1c**, or **OGTT** criteria.
- First-line treatment is **lifestyle modification** and **metformin**. Further medications are added based on **HbA1c levels** and patient characteristics.

122. Gestational Diabetes Mellitus (GDM)

1. Detailed Definition of Gestational Diabetes Mellitus (GDM):

Gestational diabetes mellitus (GDM) is a form of **diabetes** that develops during **pregnancy** (usually after 24 weeks of gestation) and typically resolves after the baby is born. It is characterised by **hyperglycaemia** that was not present before pregnancy. GDM occurs when the body cannot produce enough insulin to meet the increased demands of pregnancy, leading to elevated blood glucose levels. It increases the risk of complications for both the mother and baby during pregnancy and delivery.

2. Common Presenting Complaints and Symptoms:

GDM is often **asymptomatic** and diagnosed through routine screening in pregnancy, but in some cases, women may present with:

- **Increased thirst (polydipsia)**
- **Frequent urination (polyuria)**
- **Fatigue**
- **Blurred vision**
- **Recurrent infections** (e.g., **urinary tract infections**, **vaginal candidiasis**)

In the absence of symptoms, GDM is typically identified through **antenatal screening**.

3. First-Line Investigations:

a) Oral Glucose Tolerance Test (OGTT):

- Performed between **24-28 weeks of gestation**.
- The test involves fasting overnight, followed by a fasting blood glucose measurement. The woman then drinks a glucose solution (75g), and blood glucose is measured again at **1 hour** and **2 hours** after ingestion.

Diagnostic criteria (as per NICE guidelines):

- **Fasting glucose:** ≥ 5.6 mmol/L
- **2-hour glucose:** ≥ 7.8 mmol/L

b) Random Blood Glucose:

- Elevated blood glucose levels noted during routine antenatal appointments may prompt further investigation.

c) HbA1c:

- Not typically used to diagnose GDM, but it may be measured at the **first antenatal visit** if the woman is at risk for **undiagnosed pre-existing diabetes**.

d) Urine Testing:

- **Urine dipstick:** Glucose may be detected in the urine, but this is not a reliable diagnostic tool for GDM.

4. Explanation of Investigations:

- **OGTT:** Measures how effectively the body processes glucose after a **glucose load**, providing insight into insulin sensitivity during pregnancy.
- **Random blood glucose:** Assesses glucose levels without fasting, often used in the initial evaluation.
- **HbA1c:** Reflects average blood glucose over the past **2-3 months** and is helpful for identifying pre-existing diabetes.

5. Diagnosis Criteria for Gestational Diabetes:

According to NICE (2015) guidelines, **GDM** is diagnosed if:

- **Fasting plasma glucose** ≥ 5.6 mmol/L, or
- **2-hour plasma glucose** ≥ 7.8 mmol/L (after a 75g OGTT).

These diagnostic thresholds apply regardless of the woman's **age**, **BMI**, or **ethnicity**.

6. First-Line Therapy According to NICE Guidelines:

a) Lifestyle Modification:

1. Dietary changes:

- **Healthy balanced diet** with low glycaemic index carbohydrates, high fibre, and limited intake of **sugars** and **saturated fats**.
- Women should be advised to eat **small regular meals** and avoid foods that cause blood glucose spikes.

2. Exercise:

- Encourage **moderate physical activity** such as **walking** or **swimming**, aiming for at least **30 minutes daily** to improve insulin sensitivity.

b) Self-Monitoring of Blood Glucose:

- Women diagnosed with GDM should monitor their blood glucose levels **4 times a day** (fasting and 1 hour after each meal).

Target blood glucose levels (NICE, 2015):

- **Fasting glucose:** ≤ 5.3 mmol/L.
- **1-hour postprandial glucose:** ≤ 7.8 mmol/L.
- **2-hour postprandial glucose:** ≤ 6.4 mmol/L.

c) Pharmacological Therapy:

1. Metformin:

- First-line drug therapy if blood glucose targets are not met with lifestyle changes.
- Dosage: Start at **500 mg once daily**, titrate to a maximum of **2,000 mg/day**.
- **Mechanism:** Reduces hepatic glucose production and improves insulin sensitivity.

2. Insulin:

- Initiated if **blood glucose levels** remain above target despite lifestyle modifications or metformin, or if metformin is contraindicated.
- **Short-acting insulin** is given before meals to manage postprandial hyperglycaemia, and **long-acting insulin** may be needed to control fasting glucose.
- Insulin is safe in pregnancy and is the treatment of choice if blood glucose levels remain uncontrolled.

3. Glibenclamide (sulfonylurea):

- May be considered in women who are unable to tolerate metformin or who decline insulin therapy, but it is less commonly used than insulin.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

1. **Metformin:**
 - Contraindicated in women with **severe renal impairment** or **liver disease**.
2. **Glibenclamide:**
 - Avoid in women at risk of **hypoglycaemia** or those with **renal or liver dysfunction**.

b) Second-Line Therapy:

- **Insulin** is the second-line therapy for women who cannot achieve adequate glucose control with metformin and lifestyle changes.

8. Routine Monitoring and Follow-Up:

1. **Blood Glucose Monitoring:**
 - Women should continue **self-monitoring** of blood glucose daily throughout pregnancy.
2. **Foetal Monitoring:**
 - Women with GDM are monitored closely for **foetal growth** using **ultrasound** to check for **macrosomia** (large baby) and **amniotic fluid levels**.
3. **Postpartum Monitoring:**
 - **OGTT** is performed **6-13 weeks postpartum** to ensure glucose levels have returned to normal.
 - Annual screening for **Type 2 diabetes** is recommended as women with GDM are at increased risk of developing T2DM.

9. Complications:

1. **Maternal Complications:**
 - Increased risk of **pre-eclampsia**, **caesarean section**, and **future Type 2 diabetes**.
2. **Foetal Complications:**
 - **Macrosomia** (large birth weight), which increases the risk of **birth trauma**.
 - **Neonatal hypoglycaemia** (low blood sugar at birth).
 - Higher risk of **jaundice**, **respiratory distress syndrome**, and **preterm birth**.

Summary of Key Points for Gestational Diabetes Mellitus:

- **GDM** is diagnosed during pregnancy using the **OGTT** and should be managed with **lifestyle modification**, **metformin**, and **insulin** if necessary.
- Blood glucose levels should be tightly controlled to reduce risks to both the mother and the baby.
- Women with **GDM** are at increased risk of developing **Type 2 diabetes** later in life and should be screened regularly postpartum.

123. Pre-Existing Diabetes in Pregnancy

1. Detailed Definition of Pre-Existing Diabetes in Pregnancy:

Pre-existing diabetes in pregnancy refers to women who have **Type 1** or **Type 2 diabetes mellitus** before becoming pregnant. Pregnancy in women with pre-existing diabetes carries higher risks for both maternal and foetal complications. Optimal **glycaemic control** before and during pregnancy is crucial to minimise these risks and improve pregnancy outcomes.

2. Common Presenting Complaints and Symptoms:

Women with **pre-existing diabetes** often have well-established symptoms related to their diabetes, but pregnancy may exacerbate or complicate their condition:

- **Polyuria:** Frequent urination due to osmotic diuresis.
- **Polydipsia:** Excessive thirst.
- **Fatigue:** Resulting from poor glucose control.
- **Hypoglycaemia:** Pregnant women, especially those with **Type 1 diabetes**, may experience more frequent episodes of **low blood sugar** due to increased insulin sensitivity, especially in the first trimester.

Pregnancy may increase insulin requirements as gestation progresses, especially during the **second and third trimesters** due to increased insulin resistance from **placental hormones**.

3. First-Line Investigations:

a) Blood Glucose Monitoring:

- **Frequent blood glucose testing** is essential. Women should monitor their blood glucose levels **before and after meals** and at bedtime.
- **Target blood glucose levels** during pregnancy:
 - **Fasting blood glucose:** 3.5–5.9 mmol/L.
 - **1-hour postprandial:** ≤7.8 mmol/L.
 - **2-hour postprandial:** ≤6.4 mmol/L.

b) HbA1c (Glycated Haemoglobin):

- **HbA1c** should be monitored regularly. The goal for women planning pregnancy or already pregnant is an **HbA1c of ≤48 mmol/mol (6.5%)**. Lower levels reduce the risk of congenital malformations.
- For women with **high HbA1c levels** early in pregnancy, intensive glycaemic control is required to reduce risks.

c) Kidney Function Tests:

- **Serum creatinine** and **urine albumin ratio (ACR)** should be measured regularly to assess for **diabetic nephropathy**. Pregnancy increases the risk of kidney complications.

d) Retinal Screening:

- Pre-existing diabetes increases the risk of **diabetic retinopathy**, which can worsen during pregnancy. Women should have a **retinal assessment** before conception, early in pregnancy, and again during pregnancy.

e) Foetal Monitoring:

- Regular **ultrasound scans** are used to monitor foetal growth and check for **macrosomia** (large baby), which is a common complication of diabetes in pregnancy.

4. Explanation of Investigations:

- **Blood glucose monitoring:** Ensures tight control to avoid both hyperglycaemia and hypoglycaemia during pregnancy.
- **HbA1c:** Reflects long-term blood glucose levels, with a target of **≤48 mmol/mol** being essential for reducing the risk of congenital anomalies.
- **Kidney function tests:** Monitor for kidney damage, as diabetes can worsen renal function during pregnancy.
- **Retinal screening:** Pregnancy can accelerate the progression of **diabetic retinopathy**, making regular eye checks necessary.

5. Diagnosis Criteria for Pre-Existing Diabetes in Pregnancy:

Women with pre-existing diabetes will have been diagnosed before pregnancy with:

- **Fasting glucose ≥ 7.0 mmol/L**, or
- **Random glucose ≥ 11.1 mmol/L**, or
- **HbA1c ≥ 48 mmol/mol (6.5%)**, or
- **OGTT 2-hour glucose ≥ 11.1 mmol/L**.

Diagnosis should be confirmed prior to pregnancy or at the **first antenatal visit**.

6. First-Line Therapy According to Guidelines:

a) Insulin Therapy:

1. **Basal-bolus regimen:**
 - **Short-acting insulin** is administered before meals to control postprandial hyperglycaemia, and **long-acting insulin** provides basal coverage.
 - Insulin doses should be adjusted frequently based on **self-monitoring of blood glucose**.
2. **Insulin pump therapy (Continuous subcutaneous insulin infusion - CSII):**
 - May be used for women with **Type 1 diabetes** or those who struggle to achieve glycaemic control with multiple daily injections.

b) Self-Monitoring of Blood Glucose:

- Blood glucose should be monitored **before meals, 1 hour after meals, and at bedtime**.
- Targets:
 - **Fasting glucose:** 3.5–5.9 mmol/L.
 - **1-hour postprandial:** ≤ 7.8 mmol/L.
 - **2-hour postprandial:** ≤ 6.4 mmol/L.

c) Dietary and Lifestyle Advice:

1. **Dietary changes:**
 - **Balanced diet** with low glycaemic index carbohydrates.
 - Encourage **frequent small meals** and limit foods that cause rapid glucose spikes.
 - Weight management is critical, especially in **Type 2 diabetes**.
2. **Exercise:**
 - Regular **moderate physical activity** (e.g., walking, swimming) to improve insulin sensitivity.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

1. **Oral hypoglycaemic agents** (e.g., **metformin**, **sulfonylureas**) should generally be discontinued in women with **Type 1 diabetes** in favour of **insulin therapy**. Metformin may be continued in women with **Type 2 diabetes** if glycaemic control is adequate.
2. **ACE inhibitors** and **ARBs** (used for kidney protection in non-pregnant women) should be stopped before pregnancy due to the risk of **foetal abnormalities**.

b) Second-Line Therapy:

1. **Metformin:**
 - May be used in women with **Type 2 diabetes** if insulin alone is not sufficient.
 - **Dosage:** Start at **500 mg once daily**, titrate up to a maximum of **2,000 mg daily**.
 - **Mechanism:** Reduces hepatic glucose production and improves insulin sensitivity.

8. Routine Monitoring and Follow-Up:

1. **HbA1c:**

- Should be checked **monthly** throughout pregnancy to monitor glycaemic control. Aim for **HbA1c $\leq$ 48 mmol/mol (6.5%)**.
- 2. **Blood glucose monitoring:**
 - Women should check their glucose **multiple times daily** and adjust insulin based on blood glucose levels.
- 3. **Kidney function:**
 - **Serum creatinine** and **urine ACR** should be checked regularly to monitor for worsening **diabetic nephropathy**.
- 4. **Retinal screening:**
 - Women should have regular eye checks to monitor for the progression of **diabetic retinopathy**.
- 5. **Foetal monitoring:**
 - **Ultrasound scans** every **4 weeks** from 28 weeks to monitor for **macrosomia** and other growth abnormalities.

9. Complications:

1. **Maternal Complications:**
 - Increased risk of **pre-eclampsia**, **preterm labour**, **caesarean section**, and **hypoglycaemia**.
2. **Foetal Complications:**
 - **Macrosomia:** Increases the risk of **shoulder dystocia** and **birth trauma**.
 - **Congenital malformations:** Higher risk if glycaemic control is poor during early pregnancy.
 - **Neonatal hypoglycaemia:** Due to foetal hyperinsulinemia.
 - Increased risk of **stillbirth** or **miscarriage** in poorly controlled diabetes.

10. Postpartum Care:

1. **Blood glucose monitoring:**
 - Women with **Type 1 diabetes** should continue insulin post-delivery, although insulin requirements often decrease temporarily after delivery.
 - Women with **Type 2 diabetes** may be able to switch back to **oral hypoglycaemic agents** such as **metformin**, but this should be based on postpartum glucose monitoring.
2. **Breastfeeding:**
 - Women with diabetes are encouraged to breastfeed, but insulin or metformin should be used cautiously. Both are generally safe during breastfeeding.
3. **Long-term risk:**
 - Women with **pre-existing diabetes** should be monitored for **complications** such as **diabetic retinopathy** and **nephropathy** after pregnancy.

Summary of Key Points for Pre-Existing Diabetes in Pregnancy:

- Women with **Type 1** or **Type 2 diabetes** before pregnancy require **intensive monitoring** and **glycaemic control** throughout pregnancy.
- **Insulin therapy** is the mainstay of treatment, and **frequent blood glucose monitoring** is essential.
- Good control of **HbA1c** before and during pregnancy reduces the risk of maternal and foetal complications, including **macrosomia** and **congenital malformations**.

- Postpartum care includes close monitoring of **blood glucose** and continued management of diabetes.

124. Diabetic Ketoacidosis (DKA)

1. Detailed Definition of Diabetic Ketoacidosis (DKA):

Diabetic ketoacidosis (DKA) is a serious and life-threatening complication of **diabetes mellitus**, most commonly associated with **Type 1 diabetes**, although it can occasionally occur in **Type 2 diabetes** under extreme stress (e.g., sepsis, myocardial infarction). DKA is characterised by **hyperglycaemia**, **ketonaemia**, and **metabolic acidosis** due to insulin deficiency, resulting in increased **lipolysis**, ketone body production, and subsequent metabolic acidosis. The condition requires immediate medical attention and intensive treatment.

- **Incidence:** DKA may occur in existing Type 1 diabetics or be the **first presentation** of Type 1 diabetes (approximately **6%** of cases).
- **Mortality:** Despite its severity, mortality has significantly decreased from **8% to <1%** over the past 20 years due to advances in treatment.

2. Pathophysiology:

DKA is caused by **uncontrolled lipolysis**, not proteolysis. Insulin deficiency results in increased **lipolysis**, which generates an excess of **free fatty acids**. These fatty acids are transported to the liver and converted into **ketone bodies** (**acetone**, **acetoacetate**, and **β-hydroxybutyrate**), leading to **ketonaemia** and **acidosis**.

Precipitating Factors:

1. **Infection:** The most common cause.
2. **Missed insulin doses:** Common in non-compliant patients or those unable to self-manage.
3. **Myocardial infarction:** Stress increases insulin demand.
4. Other stressors: **Trauma**, **surgery**, **alcohol use**, or **drugs** (such as corticosteroids).

3. Common Presenting Complaints and Symptoms:

DKA typically presents with **acute onset** of symptoms, which include:

- **Abdominal pain:** Commonly reported.
- **Polyuria:** Increased urination due to osmotic diuresis from hyperglycaemia.
- **Polydipsia:** Excessive thirst due to dehydration.
- **Kussmaul respiration:** Deep, laboured breathing as the body attempts to correct acidosis by expelling carbon dioxide.
- **Acetone-smelling breath:** Fruity or "pear drops" odour caused by ketones (particularly acetone).
- **Fatigue** and **lethargy:** Due to electrolyte imbalance and dehydration.
- **Confusion**, **drowsiness**, or **coma** in severe cases.

4. Diagnostic Criteria:

The diagnosis of DKA involves identifying hyperglycaemia, ketonaemia, and metabolic acidosis. Diagnostic thresholds vary slightly depending on the criteria used:

American Diabetes Association (2009)	Joint British Diabetes Societies (2013)
Glucose > 13.8 mmol/L	Glucose > 11 mmol/L or known diabetes
pH < 7.3	pH < 7.3
Serum bicarbonate < 18 mmol/L	Bicarbonate < 15 mmol/L

Anion gap > 10	Ketones > 3 mmol/L or urine ketones ++ on dipstick
--------------------------	--

5. First-Line Therapy According to Guidelines:

a) Fluid Replacement:

- Patients with DKA are typically **5-8 litres** fluid deplete. Fluid resuscitation is the most important initial step to restore circulatory volume and improve renal perfusion.
- **0.9% sodium chloride** (normal saline) is the fluid of choice, even if the patient is acidotic.

b) Insulin Therapy:

- An **intravenous (IV) insulin infusion** should be started at **0.1 units/kg/hour** to suppress ketogenesis and reduce blood glucose levels.
- Once blood glucose falls below **14 mmol/L**, switch to an infusion of **10% dextrose** at **125 mL/hour** to prevent **hypoglycaemia** while continuing insulin to clear ketones.

c) Potassium Replacement:

- **Serum potassium** is often **high on admission** due to acidosis, but insulin therapy shifts potassium intracellularly, often leading to **hypokalaemia**.
- Replace potassium as follows:
 - **Potassium >5.5 mmol/L**: No replacement required.
 - **Potassium 3.5–5.5 mmol/L**: Add **40 mmol/L** potassium to each litre of IV fluids.
 - **Potassium <3.5 mmol/L**: Urgent replacement needed; insulin may need to be paused until potassium is corrected.

d) Monitoring:

- **Hourly monitoring** of blood glucose and ketones.
- **Frequent checks** of electrolytes (especially potassium), bicarbonate, and venous pH.

6. Example Fluid Regimen (JBDS Guidelines):

A typical **fluid replacement regimen** for a patient with **systolic BP ≥90 mmHg**:

Fluid	Volume
0.9% sodium chloride 1L	Over 1 hour
0.9% sodium chloride 1L with potassium chloride	Over 2 hours
0.9% sodium chloride 1L with potassium chloride	Over 2 hours
0.9% sodium chloride 1L with potassium chloride	Over 4 hours
0.9% sodium chloride 1L with potassium chloride	Over 4 hours
0.9% sodium chloride 1L with potassium chloride	Over 6 hours

Note: Slower infusion rates may be required for **young adults (aged 18-25 years)** due to an increased risk of **cerebral oedema**.

7. Criteria for DKA Resolution:

DKA is considered resolved when:

1. **Blood ketones <0.6 mmol/L.**
2. **pH >7.3.**
3. **Bicarbonate >15 mmol/L.**

Once these criteria are met, and the patient is able to eat and drink, they can be transitioned to **subcutaneous insulin**.

8. Further Management:

- **Long-acting insulin** should be continued throughout the episode of DKA, but **short-acting insulin** should be paused while the patient is on an insulin infusion.
- Once the patient is stable and able to eat, they should resume their usual **subcutaneous insulin** regimen.

9. Complications of DKA and Its Treatment:

DKA-Related Complications:

- **Gastric stasis.**
- **Thromboembolism.**
- **Arrhythmias:** Secondary to hyperkalaemia or iatrogenic hypokalaemia.
- **Acute respiratory distress syndrome (ARDS).**
- **Acute kidney injury (AKI):** Due to severe dehydration.

Treatment-Related Complications:

- **Cerebral oedema:** Particularly in children and young adults. Symptoms include **headache, confusion, irritability, and visual disturbance**. This usually occurs **4-12 hours** after starting treatment and requires **urgent CT head** and **senior review** if suspected.
- **Hypoglycaemia:** Caused by insulin therapy.
- **Hypokalaemia:** Caused by insulin driving potassium into cells.
- **Iatrogenic fluid overload:** Leading to **pulmonary oedema**.

10. Monitoring and Follow-Up:

1. Frequent Monitoring:

- **Hourly glucose and ketone levels.**
- **Electrolyte monitoring** (especially potassium and sodium).
- **Venous blood gases** to assess acidosis correction.

2. Specialist Review:

- Patients should have a **diabetes specialist nurse** and **endocrinologist review** before discharge to discuss long-term management and to prevent future DKA episodes.

Summary of Key Points for Diabetic Ketoacidosis:

- DKA is a medical emergency seen primarily in **Type 1 diabetes**, triggered by **infection, missed insulin doses**, or other stressors.
- Management focuses on **fluid resuscitation, insulin therapy, and correction of electrolyte imbalances**, particularly potassium.
- Close monitoring is essential to avoid complications, including **cerebral oedema, hypokalaemia, and hypoglycaemia**.
- DKA is resolved when **pH >7.3, ketones <0.6 mmol/L**, and **bicarbonate >15 mmol/L**, allowing for a switch back to subcutaneous insulin.

125. Hyperosmolar Hyperglycaemic State (HHS)

1. Detailed Definition of Hyperosmolar Hyperglycaemic State (HHS):

Hyperosmolar hyperglycaemic state (HHS) is a life-threatening complication of **Type 2 diabetes mellitus**, characterised by **severe hyperglycaemia** and **dehydration** without significant ketoacidosis. HHS occurs due to insufficient insulin to prevent hyperglycaemia but enough to prevent ketogenesis. It typically develops over several days or even weeks and is often precipitated by infection, illness, or inadequate diabetes management.

2. Common Presenting Complaints and Symptoms:

HHS develops more insidiously than diabetic ketoacidosis (DKA) and often presents with:

- **Profound dehydration:** Dry mucous membranes, decreased skin turgor.
- **Polyuria and polydipsia:** Excessive urination and thirst due to osmotic diuresis from hyperglycaemia.
- **Confusion, drowsiness, or coma:** Neurological symptoms are common, reflecting the severity of dehydration and hyperosmolality.
- **Weakness and fatigue.**
- **Visual disturbances:** May occur due to osmotic changes in the lens of the eye.
- **Hypotension and tachycardia:** Due to volume depletion.
- Unlike DKA, **abdominal pain, Kussmaul breathing, and acetone-smelling breath** are typically **absent**.

3. First-Line Investigations:

a) Blood Glucose:

- Blood glucose levels in HHS are typically **extremely elevated: >30 mmol/L** (often >40 mmol/L).

b) Serum Osmolality:

- A key diagnostic feature of HHS is hyperosmolality: **>320 mOsm/kg**.
 - Calculated osmolality = **2(Na) + glucose + urea**.

c) Serum Electrolytes:

- **Sodium:** Often elevated due to dehydration.
- **Potassium:** May be normal or low; careful monitoring is required during treatment.
- **Urea and creatinine:** Typically elevated due to dehydration and possible acute kidney injury (AKI).

d) Arterial or Venous Blood Gases:

- **pH is usually >7.3** with **bicarbonate >15 mmol/L**, indicating the absence of significant acidosis (unlike in DKA).

e) Urine Dipstick and Blood Ketones:

- Urine ketones are generally absent or only mildly positive, and blood ketones are usually <3 mmol/L.

4. Explanation of Investigations:

- **Blood glucose:** Reflects the hyperglycaemia characteristic of HHS.
- **Serum osmolality:** Assesses the degree of dehydration and hyperosmolality, a key feature of HHS.
- **Electrolytes:** Assess for dehydration-related imbalances, especially sodium and potassium.
- **Blood gases:** Confirm the absence of significant acidosis.

5. Diagnostic Criteria for Hyperosmolar Hyperglycaemic State (HHS):

The diagnosis of HHS is based on the following criteria:

- **Severe hyperglycaemia:** Blood glucose **>30 mmol/L**.
- **Serum osmolality >320 mOsm/kg**.
- **No significant ketonaemia or acidosis:** **pH >7.3** and **bicarbonate >15 mmol/L**.
- **Profound dehydration** with clinical features such as hypotension, dry mucous membranes, and tachycardia.

6. First-Line Therapy According to Guidelines:

a) Fluid Replacement:

- **IV fluid replacement** is the mainstay of HHS management due to significant dehydration.
- Start with **0.9% sodium chloride (normal saline)**. In the first hour, give **1 litre** of fluid.
- Continue fluid therapy based on clinical and biochemical assessment. Aim to replace around **6-9 litres** over **24 hours**. Care must be taken not to replace fluids too rapidly to avoid complications such as **cerebral oedema**.

b) Insulin Therapy:

- **Insulin** is not the immediate priority in HHS as it is in DKA.
- Start **low-dose insulin** only if blood glucose is **not decreasing** with fluid therapy alone. A starting infusion rate of **0.05 units/kg/hour** is usually sufficient to prevent rapid changes in osmolality and blood glucose.

c) Electrolyte Monitoring and Replacement:

- **Potassium** levels need careful monitoring. Potassium may be normal initially but can drop with insulin therapy or after fluid resuscitation.
 - If **potassium <3.5 mmol/L**, potassium replacement should be initiated before starting insulin therapy.
- Replace potassium according to levels:
 - **Potassium >5.5 mmol/L**: No replacement needed.
 - **Potassium 3.5–5.5 mmol/L**: Add **20-40 mmol/L** of potassium to IV fluids.
 - **Potassium <3.5 mmol/L**: Urgent replacement is needed.

d) Monitoring:

- **Hourly monitoring** of blood glucose, electrolytes (especially potassium), and osmolality is critical.
- **Fluid balance** must be closely monitored to prevent over-hydration or under-resuscitation.
- Venous blood gases should be checked regularly to monitor pH and bicarbonate levels.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Rapid fluid replacement** should be avoided, especially in elderly patients, as it may lead to **cerebral oedema** or **heart failure**.
- Insulin should not be given immediately if **serum potassium is low** (<3.5 mmol/L), as this can worsen hypokalaemia.

b) Second-Line Therapy:

- In cases where blood glucose does not improve with fluids alone, a **low-dose insulin infusion** can be started (0.05 units/kg/hour).
- Monitor for signs of **cerebral oedema** in cases where osmolality drops too quickly with fluid replacement.

8. Routine Monitoring and Follow-Up:

1. Blood Glucose Monitoring:

- Monitor blood glucose **hourly** to ensure a gradual decline.

2. Serum Osmolality Monitoring:

- Monitor serum osmolality **every 2-4 hours** during treatment. Avoid rapid decreases in osmolality, as this can lead to **cerebral oedema**.

3. Electrolyte Monitoring:

- Regularly check **potassium, sodium, and bicarbonate** levels to guide fluid and insulin therapy.
4. **Fluid Balance:**
- Monitor input and output to assess the effectiveness of rehydration and avoid fluid overload.

9. Complications of HHS and Its Treatment:

HHS-Related Complications:

- **Thromboembolism:** Dehydration and hyperosmolality increase the risk of thrombotic events such as **deep vein thrombosis** and **pulmonary embolism**.
- **Acute kidney injury (AKI):** Due to profound dehydration and reduced renal perfusion.

Treatment-Related Complications:

- **Cerebral oedema:** Due to rapid correction of osmolality. Symptoms include **headache, confusion, and neurological deterioration**.
- **Hypoglycaemia:** Can occur if insulin is given without adequate glucose monitoring or if fluids alone cause rapid glucose reduction.
- **Hypokalaemia:** May result from insulin therapy shifting potassium into cells.

10. Resolution of HHS:

The resolution of HHS is defined by:

1. **Normalisation of osmolality:** <320 mOsm/kg.
2. **Blood glucose levels** within the target range, typically **10-15 mmol/L**.
3. Correction of **electrolyte imbalances** and **rehydration**.

Once the patient is stable, insulin therapy can be transitioned to a **subcutaneous regimen**, and the patient can resume **oral intake**.

Summary of Key Points for Hyperosmolar Hyperglycaemic State (HHS):

- **HHS** is a complication primarily of **Type 2 diabetes mellitus**, characterised by **severe hyperglycaemia** and **dehydration** without significant ketosis or acidosis.
- Management focuses on **fluid resuscitation, electrolyte replacement**, and cautious **insulin therapy** to avoid complications such as **cerebral oedema** and **thromboembolism**.
- Monitoring for **electrolyte imbalances**, particularly **potassium**, is essential to guide safe management.
- The gradual correction of hyperosmolality and dehydration is critical to avoid **neurological complications** such as cerebral oedema.

126. Diabetic Nephropathy

1. Detailed Definition of Diabetic Nephropathy:

Diabetic nephropathy is a serious complication of **diabetes mellitus**, characterised by progressive damage to the **kidneys** due to chronic hyperglycaemia. It is a leading cause of **chronic kidney disease (CKD)** and **end-stage renal disease (ESRD)** in patients with diabetes. The condition is marked by **albuminuria**, declining **glomerular filtration rate (GFR)**, and ultimately, **renal failure**.

2. Common Presenting Complaints and Symptoms:

Diabetic nephropathy is often **asymptomatic** in the early stages and may only be detected via routine screening. As the disease progresses, the following symptoms may develop:

- **Proteinuria (albuminuria):** The hallmark of diabetic nephropathy, detected on urine dipstick or urine albumin ratio (ACR).
- **Oedema:** Due to the loss of protein in the urine, particularly affecting the ankles and legs.
- **Hypertension:** Often worsens as kidney function declines.
- **Fatigue:** Associated with anaemia or uraemia in advanced stages of chronic kidney disease.
- **Nausea and vomiting:** Seen in the later stages of kidney failure.
- **Reduced urine output:** In advanced renal failure, although in the early stages, urine output may be preserved or even increased.

3. First-Line Investigations:

a) Urine Albumin

Ratio (ACR):

- **Albuminuria** is the earliest marker of diabetic nephropathy.
- An **ACR** of >3 mg/mmol on a spot urine sample is suggestive of **microalbuminuria**, while >30 mg/mmol indicates **macroalbuminuria**.

b) Serum Creatinine and eGFR:

- **Serum creatinine** and **estimated GFR (eGFR)** are used to assess renal function and detect CKD.
- Progressive decline in **eGFR** is typical of worsening diabetic nephropathy.

c) Blood Pressure Measurement:

- **Hypertension** is both a cause and consequence of diabetic nephropathy. Regular BP monitoring is essential.

d) Urea and Electrolytes:

- These tests assess kidney function and may reveal elevated **urea** and **creatinine** levels as nephropathy progresses.

e) Urine Dipstick:

- A simple and quick screening test to detect **proteinuria**, which, if present, should prompt further investigation (e.g., ACR).

4. Explanation of Investigations:

- **Urine ACR:** Detects **albuminuria**, the hallmark of diabetic nephropathy. Even slight increases indicate early kidney damage.
- **Serum creatinine and eGFR:** Help to track the **progression of kidney disease**. Declining eGFR indicates worsening renal function.
- **Blood pressure measurement:** Elevated BP can worsen nephropathy and should be aggressively managed.
- **Urine dipstick:** Detects the presence of protein in the urine, suggesting early or advanced nephropathy.

5. Diagnosis Criteria for Diabetic Nephropathy:

The diagnosis of diabetic nephropathy is based on:

1. **Albuminuria:**
 - Microalbuminuria: **ACR ≥ 3 mg/mmol** but <30 mg/mmol.
 - Macroalbuminuria: **ACR ≥ 30 mg/mmol**.
2. **Declining eGFR:** eGFR <60 mL/min/1.73 m² indicates CKD.
3. **Persistent proteinuria:** Detected on urine dipstick or ACR over time.

4. **History of diabetes:** Usually present for 10 or more years.

6. First-Line Therapy According to Guidelines:

a) Glycaemic Control:

- **Tight glycaemic control** is crucial in preventing and slowing the progression of diabetic nephropathy.
- **Target HbA1c:** Aim for **48 mmol/mol (6.5%)** or as close as possible while avoiding hypoglycaemia.

b) Blood Pressure Control:

- **Target BP:** Aim for **<130/80 mmHg** if albuminuria is present.
- **ACE inhibitors** or **angiotensin receptor blockers (ARBs)** are the first-line antihypertensive medications in patients with diabetic nephropathy, regardless of whether the patient is hypertensive, as they reduce albuminuria and protect kidney function.

c) Lifestyle Modifications:

- **Salt restriction:** Reduce salt intake to **<2g/day** to manage blood pressure.
- **Protein intake:** Limit excessive protein intake (approximately 0.8-1g/kg/day) to reduce proteinuria and protect renal function.

d) Statin Therapy:

- Consider starting a **statin** (e.g., **atorvastatin 20mg** daily) if the patient has a 10-year cardiovascular risk of **≥10%**, as patients with diabetic nephropathy are at increased risk of cardiovascular disease.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **ACE inhibitors** and **ARBs** should be used cautiously if:
 - **Serum potassium** is **>5.5 mmol/L**, as these drugs can cause hyperkalaemia.
 - **Renal artery stenosis** is present, as these drugs can reduce renal perfusion.

b) Second-Line Therapy:

1. SGLT-2 Inhibitors:

- Recent evidence shows that **SGLT-2 inhibitors** (e.g., **dapagliflozin**, **empagliflozin**) can significantly reduce the progression of diabetic nephropathy and improve renal outcomes. They also provide cardiovascular benefits.
- **Mechanism:** SGLT-2 inhibitors reduce glucose reabsorption in the kidneys, leading to osmotic diuresis, which improves renal function and reduces albuminuria.

2. Non-Dihydropyridine Calcium Channel Blockers:

- Consider for blood pressure control if ACE inhibitors or ARBs are not tolerated. **Diltiazem** or **verapamil** may be used.

8. Routine Monitoring and Follow-Up:

1. Albumin

Ratio (ACR):

- Repeat every **6-12 months** to monitor the progression of albuminuria.

2. eGFR:

- Measure at least every **6 months** in patients with diabetic nephropathy or more frequently in advanced disease (e.g., **eGFR <30 mL/min/1.73 m²**).

3. Serum Potassium:

- Monitor every **3-6 months** for patients on ACE inhibitors or ARBs to detect hyperkalaemia.
4. **Blood Pressure:**
- Check regularly to ensure target levels of **<130/80 mmHg** are being met.

9. Complications:

Kidney-Related Complications:

1. **Progression to End-Stage Renal Disease (ESRD):**
 - Diabetic nephropathy is a leading cause of **dialysis** and **renal transplantation**.
2. **Acute Kidney Injury (AKI):**
 - Can be triggered by dehydration, infections, or the use of nephrotoxic medications such as **NSAIDs**.

Cardiovascular Complications:

1. **Increased Cardiovascular Risk:**
 - Diabetic nephropathy is associated with an increased risk of **myocardial infarction, stroke, and heart failure**.
2. **Hypertension:**
 - Worsened by declining kidney function, leading to increased cardiovascular morbidity.

Summary of Key Points for Diabetic Nephropathy:

- **Diabetic nephropathy** is a major cause of chronic kidney disease and end-stage renal disease, primarily affecting patients with **Type 1** and **Type 2 diabetes**.
- Early detection through **albuminuria screening** and management with **glycaemic control, blood pressure control, and ACE inhibitors/ARBs** is essential to slow disease progression.
- **SGLT-2 inhibitors** offer new therapeutic options that improve renal and cardiovascular outcomes.
- **Monitoring** involves regular checks of albuminuria, eGFR, potassium, and blood pressure.
- The condition increases the risk of cardiovascular complications and can lead to **end-stage renal disease**, requiring dialysis or transplantation.

127. Diabetic Neuropathy

1. Detailed Definition of Diabetic Neuropathy:

Diabetic neuropathy is a common complication of **diabetes mellitus**, particularly in long-standing or poorly controlled diabetes. It is characterised by **nerve damage** due to chronic **hyperglycaemia**, leading to various symptoms affecting sensory, motor, and autonomic nerves. The most common form is **peripheral neuropathy**, but **autonomic neuropathy, proximal neuropathy, and focal neuropathy** are also seen. Diabetic neuropathy can significantly impact a patient's quality of life and increase the risk of further complications, such as **foot ulcers** and **amputations**.

2. Common Presenting Complaints and Symptoms:

a) Peripheral Neuropathy:

This is the most common type, typically affecting the **legs** and **feet**.

- **Numbness or reduced sensation** (especially in the feet).
- **Tingling or burning pain**.

- **Sharp or shooting pains**, often worse at night.
- **Loss of reflexes** (e.g., ankle reflexes).
- **Muscle weakness**: In severe cases.
- **Foot ulcers**: Due to unnoticed injuries, caused by loss of sensation.

b) Autonomic Neuropathy:

Affects the **autonomic nervous system**, leading to various complications:

- **Cardiovascular**: Postural hypotension, tachycardia, silent myocardial infarctions.
- **Gastrointestinal**: Gastroparesis (delayed gastric emptying), diarrhoea, constipation.
- **Genitourinary**: Bladder dysfunction, erectile dysfunction in men.
- **Sweating abnormalities**: Reduced sweating in the extremities or increased sweating on the face and upper body.

c) Proximal Neuropathy (Diabetic Amyotrophy):

Affects the **thighs, hips, and buttocks**.

- **Muscle weakness**: Often starting in the thighs and progressing to the lower legs.
- **Sudden, severe pain** in the hips or thighs.
- Difficulty standing from a seated position or climbing stairs.

d) Focal Neuropathy:

This type affects specific nerves, often suddenly.

- **Cranial nerve palsies**: Particularly **3rd nerve palsy**, leading to **double vision**.
- **Entrapment neuropathies**: Such as **carpal tunnel syndrome**, leading to hand weakness and tingling.

3. First-Line Investigations:

a) Nerve Conduction Studies (NCS):

- Used to assess the **speed and strength of electrical impulses** along the nerves.
- Slower conduction indicates **demyelination** or **axonal loss** typical of diabetic neuropathy.

b) Electromyography (EMG):

- Measures the **electrical activity of muscles** and helps differentiate between nerve and muscle disorders.

c) Monofilament Testing:

- Used to assess **protective sensation** in the feet.
- A 10g monofilament is pressed against the skin to detect **loss of sensation**, which indicates risk for **foot ulcers**.

d) Blood Glucose and HbA1c:

- Poor glycaemic control contributes to the development and progression of diabetic neuropathy.
- **HbA1c** reflects the average blood glucose control over the previous **2-3 months**.

e) Urine Albumin Ratio (ACR):

- May be performed to assess for concurrent **diabetic nephropathy**, as many patients with neuropathy also have kidney involvement.

4. Explanation of Investigations:

- **Nerve conduction studies** and **electromyography**: Help assess the extent of nerve damage and differentiate between types of neuropathy.
- **Monofilament testing**: Assesses sensation and helps predict the risk of complications, such as foot ulcers.

- **HbA1c:** Monitors long-term glycaemic control, which is essential to prevent the progression of neuropathy.

5. Diagnosis Criteria for Diabetic Neuropathy:

Diabetic neuropathy is diagnosed based on:

1. **Clinical symptoms:** Such as numbness, pain, or weakness, especially in the feet.
2. **Loss of protective sensation:** Detected via monofilament testing or nerve conduction studies.
3. **History of diabetes:** Typically present for 10 years or more, or in poorly controlled diabetes.

There is no single test to diagnose diabetic neuropathy, and diagnosis is primarily based on clinical evaluation and **exclusion of other causes of neuropathy**, such as **alcoholism**, **vitamin B12 deficiency**, or **chronic kidney disease**.

6. First-Line Therapy According to Guidelines:

a) Glycaemic Control:

- **Tight glycaemic control** is the most effective way to slow the progression of diabetic neuropathy.
- Aim for **HbA1c <48 mmol/mol (6.5%)** without causing significant hypoglycaemia.

b) Pain Management:

Neuropathic pain can be debilitating and requires specific medications.

- **First-line medications** include:
 - **Amitriptyline:** A tricyclic antidepressant. Start at **10-25 mg at night**, titrate up as needed.
 - **Duloxetine:** A serotonin-norepinephrine reuptake inhibitor (SNRI). Usual dose: **60 mg once daily**.
 - **Gabapentin:** Start at **300 mg once daily**, increasing as needed to a maximum of **3600 mg daily**.
 - **Pregabalin:** Start at **75 mg twice daily**, can increase to **150 mg twice daily**.

c) Foot Care:

- Regular foot examinations by healthcare professionals to detect early signs of **ulcers** or **infection**.
- Patients should be educated to inspect their feet daily for **cuts**, **sores**, or **blisters** and to wear proper **footwear** to prevent injury.

d) Treatment of Autonomic Neuropathy:

1. **Postural Hypotension:** Encourage **slow position changes**, increase **fluid and salt intake**, or use medications like **fludrocortisone**.
2. **Gastroparesis:** Small, frequent meals, and prokinetic agents like **metoclopramide** or **domperidone**.
3. **Erectile Dysfunction:** **Phosphodiesterase-5 inhibitors** like **sildenafil**.
4. **Bladder Dysfunction:** Intermittent self-catheterisation or medications to relax the bladder.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Amitriptyline:** Should be used with caution in patients with **cardiac disease** or **elderly** due to the risk of **arrhythmias** and **sedation**.
- **Duloxetine:** Should be avoided in patients with **severe liver disease** or **alcoholism**.

b) Second-Line Therapy:

- **Opioid Analgesics:** May be used in severe cases where first-line therapies fail. **Tramadol** or **oxycodone** may be considered, but with caution due to the risk of dependency and side effects.
- **Capsaicin Cream:** A topical agent that may provide some relief for **localised pain**.
- **Alpha-lipoic acid:** Has been suggested in some studies to reduce pain and improve symptoms, although evidence is limited.

8. Routine Monitoring and Follow-Up:

1. **HbA1c:**
 - Monitor every **3-6 months** to ensure good glycaemic control and reduce the risk of further nerve damage.
2. **Foot Examination:**
 - Annual comprehensive foot examinations, with more frequent assessments for those at higher risk of complications.
3. **Nerve Conduction Studies:**
 - May be repeated to assess the progression of neuropathy or in cases where the diagnosis is uncertain.
4. **Renal Function:**
 - Monitor **serum creatinine** and **eGFR** periodically to assess for **diabetic nephropathy** if suspected.

9. Complications:

Foot Ulcers and Amputation:

- **Diabetic foot ulcers** are a serious complication due to the loss of sensation and delayed healing. If not managed promptly, they can lead to **infection**, **osteomyelitis**, and eventually **amputation**.

Charcot Foot:

- A rare but serious complication where nerve damage leads to **bone weakening** and **deformity** of the foot, increasing the risk of **fractures** and **ulceration**.

Cardiovascular Complications:

- Patients with **autonomic neuropathy** are at increased risk of **silent myocardial infarctions** and **sudden cardiac death** due to **postural hypotension** and abnormal heart rate responses.

Gastroparesis:

- Delayed gastric emptying can cause **nausea**, **vomiting**, and **nutritional deficiencies**.

128. Diabetic Retinopathy

1. Detailed Definition of Diabetic Retinopathy:

Diabetic retinopathy is a common and serious complication of **diabetes mellitus**, affecting the **retina** (the light-sensitive tissue at the back of the eye). It occurs due to **chronic hyperglycaemia**, which leads to damage to the small blood vessels (microangiopathy) in the retina, resulting in visual impairment and, if untreated, **blindness**. Diabetic retinopathy is classified into **non-proliferative** and **proliferative** stages, with **diabetic maculopathy** being an important cause of visual loss.

2. Common Presenting Complaints and Symptoms:

Diabetic retinopathy often progresses without symptoms until it reaches an advanced stage.

Key presenting features include:

- **Blurry vision:** This can be due to macular oedema or haemorrhage.
- **Floaters:** Tiny specks or spots that appear to drift through the visual field due to bleeding into the eye.
- **Sudden loss of vision:** Usually occurs due to vitreous haemorrhage or retinal detachment in the advanced stages.
- **Impaired night vision:** Difficulty seeing in low light conditions.
- **Gradual visual loss:** Often related to maculopathy or the formation of scar tissue.

Note: In early stages, diabetic retinopathy may be asymptomatic, emphasising the importance of **routine eye screening**.

3. First-Line Investigations:

a) Dilated Fundoscopy:

- **Direct visualisation** of the retina after dilating the pupils is the gold standard for diagnosing diabetic retinopathy. Early signs include **microaneurysms**, **haemorrhages**, and **cotton-wool spots**.

b) Optical Coherence Tomography (OCT):

- A non-invasive imaging test that provides detailed images of the retina and detects **macular oedema** and **thickening**.

c) Fundus Photography:

- **Fundus photographs** help document and monitor changes in the retina over time and are used in **diabetic retinopathy screening programmes**.

d) Fluorescein Angiography:

- A dye test that visualises the retinal blood vessels, highlighting areas of **leakage**, **ischaemia**, or **neovascularisation**.

e) Visual Acuity Testing:

- Measures the clarity of vision and helps assess the extent of visual impairment.

4. Explanation of Investigations:

- **Dilated fundoscopy:** Allows detailed examination of the retina to assess the stage of retinopathy and any complications.
- **OCT:** Essential for diagnosing **diabetic maculopathy**, which involves swelling of the macula due to fluid leakage from damaged blood vessels.
- **Fluorescein angiography:** Helps in visualising **abnormal blood vessels** or areas of **retinal ischaemia**, particularly in **proliferative diabetic retinopathy**.
- **Fundus photography:** A routine screening tool used in **annual eye screening** for diabetic patients.

5. Diagnosis Criteria for Diabetic Retinopathy:

Diabetic retinopathy is diagnosed based on the findings from **fundoscopy** and is classified as follows:

Non-Proliferative Diabetic Retinopathy (NPDR):

1. **Mild NPDR:**
 - **Microaneurysms** (tiny bulges in retinal blood vessels).
2. **Moderate NPDR:**
 - Microaneurysms, **dot and blot haemorrhages**, and **hard exudates**.
3. **Severe NPDR:**

- Large numbers of haemorrhages, **venous beading**, and **intraretinal microvascular abnormalities (IRMA)**.

Proliferative Diabetic Retinopathy (PDR):

- **Neovascularisation** (formation of new, fragile blood vessels) is the hallmark of PDR.

This can lead to:

- **Vitreous haemorrhage:** Bleeding into the gel-like substance in the centre of the eye.
- **Tractional retinal detachment:** Due to fibrous tissue pulling on the retina.

Diabetic Maculopathy:

- Involves the macula and may occur with or without retinopathy.
- **Macular oedema** is a common feature and leads to **blurred central vision**.

6. First-Line Therapy According to Guidelines:

a) Glycaemic Control:

- **Tight glycaemic control** is crucial to prevent the onset and progression of diabetic retinopathy.
- **Target HbA1c: 48 mmol/mol (6.5%)** or as close as possible without significant hypoglycaemia.

b) Blood Pressure Control:

- **Hypertension** accelerates the progression of diabetic retinopathy. Aim for a **BP target of <140/80 mmHg**.
- **ACE inhibitors** or **ARBs** are often used as part of blood pressure management.

c) Laser Photocoagulation:

- **Pan-retinal laser photocoagulation (PRP)** is used for **proliferative diabetic retinopathy** to reduce neovascularisation and prevent further complications.
- **Focal or grid laser treatment** can be used for **diabetic macular oedema** to seal leaking blood vessels.

d) Anti-VEGF Therapy:

- **Intravitreal injections** of anti-VEGF agents (e.g., **ranibizumab**, **aflibercept**) reduce **neovascularisation** and control **macular oedema** by inhibiting vascular endothelial growth factor (VEGF), a key mediator in abnormal blood vessel growth.

e) Vitrectomy:

- Surgical removal of the **vitreous gel** in cases of **non-resolving vitreous haemorrhage** or **tractional retinal detachment**.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Laser photocoagulation** may not be suitable for patients with very **poor vision** in advanced stages, where it may not improve vision.
- **Anti-VEGF injections** are contraindicated in patients with active **ocular infections**.

b) Second-Line Therapy:

1. Corticosteroid Injections:

- **Intravitreal corticosteroids** (e.g., **triamcinolone** or **dexamethasone implant**) are sometimes used for **diabetic macular oedema** not responsive to anti-VEGF therapy.

2. Combination Therapy:

- In some cases, a combination of **laser** and **anti-VEGF** therapy may be required to control both proliferative changes and macular oedema.

8. Routine Monitoring and Follow-Up:

1. Annual Screening:

- Patients with diabetes should undergo **annual retinal screening** to detect retinopathy early.

2. HbA1c Monitoring:

- HbA1c should be monitored every **3-6 months** to ensure **optimal glycaemic control** and prevent progression of retinopathy.

3. Blood Pressure Monitoring:

- Regular monitoring of blood pressure to maintain target levels and reduce retinal vascular damage.

4. OCT:

- For patients with diabetic maculopathy, **regular OCT** is essential to monitor **macular thickness** and treatment response.

9. Complications:

a) Vision Loss:

- Advanced **diabetic macular oedema** or **proliferative retinopathy** can lead to **irreversible blindness** if not treated promptly.

b) Vitreous Haemorrhage:

- Neovascular vessels are fragile and prone to bleeding, causing sudden loss of vision.

c) Tractional Retinal Detachment:

- The formation of scar tissue due to proliferative changes can lead to **retinal detachment**, further threatening vision.

d) Cataracts:

- Diabetic patients, particularly those with retinopathy, are at increased risk of **early cataract formation**.

e) Glaucoma:

- **Neovascular glaucoma** can develop if new vessels grow over the **trabecular meshwork**, obstructing fluid outflow and raising intraocular pressure.

Summary of Key Points for Diabetic Retinopathy:

- **Diabetic retinopathy** is a major complication of **diabetes mellitus**, affecting the **retinal blood vessels** and leading to potential **blindness** if untreated.
- The condition is classified into **non-proliferative** and **proliferative** stages, with **diabetic maculopathy** causing significant visual loss due to **macular oedema**.
- Early detection via **routine eye screening** and management with **glycaemic control**, **blood pressure control**, **laser therapy**, and **anti-VEGF injections** is crucial to prevent progression and preserve vision.
- **Annual screening** and **regular monitoring** of HbA1c and blood pressure are vital to managing the condition and preventing complications such as **vitreous haemorrhage** and **retinal detachment**.

129. Diabetes Insipidus

1. Detailed Definition of Diabetes Insipidus (DI):

Diabetes insipidus (DI) is a condition characterised by the **inability of the kidneys to concentrate urine**, leading to the production of large amounts of dilute urine (polyuria) and increased thirst (polydipsia). DI occurs due to a **deficiency in antidiuretic hormone (ADH)**,

also known as **vasopressin**, or **insensitivity to ADH** at the kidney level. There are two main types:

1. **Central Diabetes Insipidus (Neurogenic)**: Caused by **deficient production or secretion of ADH** from the hypothalamus or posterior pituitary gland.
2. **Nephrogenic Diabetes Insipidus**: Caused by the **kidney's inability to respond to ADH** despite its normal production.

2. Common Presenting Complaints and Symptoms:

Patients with diabetes insipidus often present with the following:

- **Polyuria**: The passage of abnormally large volumes of dilute urine (> 3 litres/day).
- **Polydipsia**: Excessive thirst due to the body's attempt to compensate for the loss of water.
- **Nocturia**: Frequently waking up at night to urinate.
- **Dehydration**: If the water intake does not match urine output, patients can become dehydrated, leading to:
 - **Dry mucous membranes**.
 - **Hypotension** and **tachycardia** (if severe).
- **Fatigue** and **lethargy**: Resulting from dehydration and electrolyte imbalances.

In **central DI**, patients may also report symptoms related to a **pituitary tumour** or trauma (e.g., headaches, visual disturbances), whereas in **nephrogenic DI**, patients may have a history of **chronic kidney disease** or use of certain medications.

3. First-Line Investigations:

a) Serum and Urine Osmolality:

- **Serum osmolality**: Increased (> 290 mOsm/kg) due to dehydration and water loss.
- **Urine osmolality**: Low (< 300 mOsm/kg) as the kidneys fail to concentrate urine.

b) Serum Electrolytes:

- **Hypernatraemia**: Due to excessive water loss and insufficient water intake.
- **Hypokalaemia** or **hypercalcaemia** may indicate an underlying cause of nephrogenic DI.

c) Water Deprivation Test (Desmopressin Stimulation Test):

- **Water deprivation** is conducted to test the body's ability to concentrate urine.
 - In **central DI**, the urine remains dilute despite water deprivation, but after the administration of **desmopressin (synthetic ADH)**, the urine osmolality will increase.
 - In **nephrogenic DI**, the urine remains dilute even after desmopressin administration, indicating renal resistance to ADH.

d) Serum ADH (Vasopressin):

- In **central DI**, ADH levels are **low** or undetectable.
- In **nephrogenic DI**, ADH levels are **normal or elevated**, but the kidneys are unresponsive to it.

e) MRI of the Brain:

- Performed if **central DI** is suspected to assess the **hypothalamus and pituitary gland** for tumours, trauma, or other structural abnormalities.

4. Explanation of Investigations:

- **Water deprivation test**: Determines the body's ability to conserve water. The addition of **desmopressin** helps differentiate between **central** and **nephrogenic DI**.

- **Serum and urine osmolality:** Reflects the inability of the kidneys to concentrate urine in DI.
- **Serum ADH levels:** Helps differentiate between **ADH deficiency** (central DI) and **ADH resistance** (nephrogenic DI).

5. Diagnosis Criteria for Diabetes Insipidus:

The diagnosis of **diabetes insipidus** is confirmed by:

1. **Polyuria** (> 3 litres/day) and **polydipsia**.
2. **Low urine osmolality** (< 300 mOsm/kg) and **high serum osmolality** (> 290 mOsm/kg).
3. A **positive water deprivation test**:
 - **Central DI:** Improvement in urine osmolality after desmopressin.
 - **Nephrogenic DI:** No response to desmopressin.

6. First-Line Therapy According to Guidelines:

a) Central Diabetes Insipidus:

- **Desmopressin** (DDAVP) is the first-line treatment:
 - **Intranasal spray:** 10-20 mcg once or twice daily.
 - **Oral tablets:** 0.1-0.4 mg daily in divided doses.
- Desmopressin acts as a **synthetic ADH**, restoring water reabsorption in the kidneys.

b) Nephrogenic Diabetes Insipidus:

- **Thiazide diuretics** (e.g., **hydrochlorothiazide**): Used to reduce urine output by inducing mild dehydration, leading to increased water reabsorption in the kidneys.
 - Dosage: 25-50 mg daily.
- **Low-sodium diet:** Helps reduce the volume of urine.
- **Amiloride:** Can be added in patients with **lithium-induced nephrogenic DI** to counteract the effects of lithium on the kidneys.
 - Dosage: 5-10 mg daily.
- **NSAIDs** (e.g., **indomethacin**) may reduce urine output by inhibiting prostaglandins, which antagonise the effects of ADH.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Desmopressin** should be used cautiously in patients with a history of **heart failure** or **hyponatraemia** as it can lead to **water retention** and **dilutional hyponatraemia**.
- **Thiazide diuretics** may not be suitable for patients with **severe renal impairment**.

b) Second-Line Therapy:

- **Amiloride** or **NSAIDs** (e.g., **indomethacin**) may be used in conjunction with **thiazide diuretics** in nephrogenic DI if adequate control is not achieved with the first-line agents.

8. Routine Monitoring and Follow-Up:

1. Electrolyte Monitoring:

- Regular monitoring of **serum sodium** to avoid **hyponatraemia** in patients on **desmopressin**.
- Monitoring of **potassium** levels in patients on **thiazide diuretics**.

2. Fluid Balance:

- Monitoring of **daily fluid intake and urine output** to ensure balance and prevent dehydration or fluid overload.

3. Renal Function:

- Regular monitoring of **renal function** in patients with nephrogenic DI on thiazides or NSAIDs.

9. Complications:

a) Dehydration:

- Untreated or poorly managed DI can lead to **severe dehydration**, which may cause **hypotension, shock, or renal failure**.

b) Electrolyte Imbalance:

- **Hypernatraemia** can occur if the patient is unable to drink enough fluids to compensate for the high urine output.
- **Hyponatraemia** can occur in patients on **desmopressin** if water intake exceeds urine output.

c) Permanent Kidney Damage:

- Prolonged **nephrogenic DI** may cause permanent **renal impairment**, especially if secondary to **lithium use** or other nephrotoxic medications.

Summary of Key Points for Diabetes Insipidus:

- **Diabetes insipidus** is characterised by **polyuria, polydipsia**, and **dilute urine** due to ADH deficiency or renal insensitivity to ADH.
- **First-line investigations** include **serum and urine osmolality**, the **water deprivation test**, and **serum ADH levels**.
- **Desmopressin** is the first-line treatment for **central DI**, while **thiazide diuretics** and **low-sodium diets** are used for **nephrogenic DI**.
- Regular monitoring of **fluid balance, electrolytes**, and **renal function** is essential for managing complications such as dehydration and electrolyte imbalances.

130. Hypothyroidism

1. Detailed Definition of Hypothyroidism:

Hypothyroidism is a condition where the **thyroid gland** fails to produce enough **thyroid hormones** (thyroxine [T4] and triiodothyronine [T3]) to meet the body's metabolic needs. This leads to a general **slowing down of metabolic processes** and can affect multiple organ systems. It can be classified into:

- **Primary hypothyroidism**: Due to dysfunction of the thyroid gland itself (e.g., autoimmune, iodine deficiency).
- **Secondary hypothyroidism**: Due to a failure of the pituitary gland to secrete **thyroid-stimulating hormone (TSH)**.

2. Common Presenting Complaints and Symptoms:

Hypothyroidism tends to develop gradually, with symptoms worsening over time. Common symptoms include:

- **Fatigue and lethargy**: One of the most common symptoms, related to slowed metabolism.
- **Weight gain**: Despite reduced appetite.
- **Cold intolerance**: Feeling unusually cold even in warm environments.
- **Constipation**: Due to slowed gastrointestinal motility.
- **Bradycardia**: Slow heart rate.
- **Dry skin and brittle hair**: Skin may also be rough and pale.
- **Hair loss**: Thinning of hair, including the outer third of the eyebrows.

- **Hoarse voice:** Due to swelling of the vocal cords.
- **Menstrual irregularities:** Heavy menstrual bleeding (menorrhagia) or absent periods (amenorrhoea).
- **Depression and memory problems:** Cognitive slowing and difficulty concentrating.

Signs on examination may include:

- **Bradycardia.**
- **Delayed relaxation of deep tendon reflexes.**
- **Puffy face, periorbital oedema, and goitre** (if caused by autoimmune thyroiditis).
- **Coarse and dry skin.**

3. First-Line Investigations:

a) Thyroid Function Tests (TFTs):

- **TSH (Thyroid-Stimulating Hormone):**
 - **Elevated** in primary hypothyroidism.
 - **Low or normal** in secondary hypothyroidism.
- **Free T4 (Thyroxine):**
 - **Low** in both primary and secondary hypothyroidism.
- **Free T3:** Not routinely measured but can be **low** in more severe cases.

b) Anti-Thyroid Antibodies:

- **Thyroid peroxidase antibodies (TPOAb):**
 - Elevated in **autoimmune hypothyroidism**, particularly **Hashimoto's thyroiditis**.

c) Lipid Profile:

- **Hyperlipidaemia** is common in hypothyroidism due to reduced lipid metabolism, particularly raised **LDL cholesterol** and **triglycerides**.

4. Explanation of Investigations:

- **TSH:** A high TSH with low T4 confirms **primary hypothyroidism** as the pituitary attempts to stimulate a failing thyroid gland.
- **Free T4:** Low levels reflect reduced production of thyroid hormones by the thyroid gland.
- **Anti-TPO antibodies:** Help diagnose **autoimmune thyroiditis (Hashimoto's disease)**, a common cause of hypothyroidism.
- **Lipid profile:** Raised cholesterol levels are commonly associated with hypothyroidism.

5. Diagnosis Criteria for Hypothyroidism:

Primary hypothyroidism is diagnosed when:

- **TSH is elevated** (usually >10 mIU/L).
- **Free T4 is low.**

Subclinical hypothyroidism:

- **TSH is elevated** (typically 4-10 mIU/L).
- **Free T4 is normal.**

Secondary hypothyroidism:

- **TSH is low or normal.**
- **Free T4 is low.**

The presence of **anti-TPO antibodies** is suggestive of **Hashimoto's thyroiditis** as the underlying cause.

6. First-Line Therapy According to Guidelines:

a) Levothyroxine:

- The first-line treatment for hypothyroidism is **levothyroxine**, a synthetic form of thyroxine (T4).
- **Initial dose:** Typically **50-100 micrograms** once daily. In elderly patients or those with coronary artery disease, a **lower starting dose** (e.g., 25 micrograms) is recommended.
- **Dosage adjustment:**
 - The dose is adjusted based on **TSH levels**, aiming for a normal TSH (usually within the lower half of the reference range).
 - Recheck **TSH** levels every **6-8 weeks** after starting treatment or following a dose change.

b) Lifestyle Advice:

- Patients should be advised to take **levothyroxine on an empty stomach**, ideally **30 minutes before breakfast**, as food and some medications (e.g., iron, calcium) can interfere with absorption.
- Educate patients about the importance of **adherence** to medication for lifelong management of hypothyroidism.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Over-treatment with levothyroxine** can lead to **iatrogenic hyperthyroidism**, which increases the risk of **atrial fibrillation** and **osteoporosis**, especially in elderly patients.
- Use caution in patients with **cardiovascular disease**, as levothyroxine increases **heart rate** and **myocardial oxygen demand**.

b) Second-Line Therapy:

- In some cases where T4 alone does not relieve symptoms, combination therapy with **liothyronine (T3)** may be considered, though this is not commonly recommended due to limited evidence of benefit and potential risks.

8. Routine Monitoring and Follow-Up:

1. TSH Monitoring:

- After initiating or changing **levothyroxine dosage**, recheck **TSH levels** after **6-8 weeks**. Once stable, annual monitoring is recommended.

2. Clinical Monitoring:

- Regular assessment for symptom improvement (e.g., energy levels, weight, cold intolerance).

3. Lipid Profile:

- Repeat lipid profiles if dyslipidaemia was present prior to treatment to monitor for improvement after thyroid function normalises.

9. Complications of Hypothyroidism:

a) Myxoedema Coma:

- A rare but life-threatening complication of severe, untreated hypothyroidism. It is characterised by:
 - **Hypothermia.**
 - **Bradycardia.**
 - **Hypotension.**
 - **Hypoventilation** and **hypoglycaemia.**

- This requires **immediate hospitalisation**, **intravenous levothyroxine**, and **supportive care**.

b) Cardiovascular Complications:

- Hypothyroidism is associated with **dyslipidaemia**, which increases the risk of **atherosclerosis**, **myocardial infarction**, and **stroke**.

c) Infertility and Pregnancy Complications:

- **Untreated hypothyroidism** can lead to **infertility** or complications in pregnancy, including **pre-eclampsia**, **anaemia**, and **miscarriage**.

Summary of Key Points for Hypothyroidism:

- **Hypothyroidism** is a common endocrine disorder where the thyroid gland produces insufficient thyroid hormones, leading to a general slowing of metabolic processes.
- Symptoms include **fatigue**, **weight gain**, **cold intolerance**, and **bradycardia**, among others.
- **Thyroid function tests** (TSH and free T4) are essential for diagnosis, and treatment involves **lifelong levothyroxine** replacement therapy, adjusted according to **TSH levels**.
- Regular monitoring of **TSH** and **lipids** is necessary to avoid under- or over-treatment, and patients should be monitored for complications like **myxoedema coma** and **cardiovascular disease**.

131. Thyrotoxicosis

1. Detailed Definition of Thyrotoxicosis:

Thyrotoxicosis refers to the clinical syndrome of **excess thyroid hormones** (thyroxine [T4] and triiodothyronine [T3]) in the bloodstream, leading to **hypermetabolism**. It can be caused by several underlying conditions, including **Graves' disease**, **toxic multinodular goitre**, **toxic adenoma**, or **thyroiditis**. When thyrotoxicosis is due to excessive thyroid hormone production by the thyroid gland, it is referred to as **hyperthyroidism**.

2. Common Presenting Complaints and Symptoms:

Patients with thyrotoxicosis often present with symptoms related to an **increased metabolic rate** and **sympathetic nervous system activity**:

- **Weight loss:** Despite normal or increased appetite.
- **Heat intolerance:** Due to increased heat production.
- **Palpitations:** Due to tachycardia or atrial fibrillation.
- **Tremor:** Fine tremor of the hands.
- **Sweating:** Excessive perspiration.
- **Increased bowel movements** or **diarrhoea**.
- **Anxiety, nervousness, irritability.**
- **Muscle weakness** or **proximal myopathy**.
- **Fatigue:** Despite the hyperactive state, patients may feel tired.
- **Menstrual irregularities:** Oligomenorrhoea or amenorrhoea in women.

Signs on examination may include:

- **Tachycardia** or **atrial fibrillation**.
- **Goitre:** Enlarged thyroid, which may be smooth (Graves' disease) or nodular (multinodular goitre).
- **Exophthalmos** or **proptosis:** Seen in Graves' disease due to retro-orbital tissue inflammation.
- **Lid lag** and **lid retraction**.

- **Brisk reflexes.**
- **Warm, moist skin.**

3. First-Line Investigations:

a) Thyroid Function Tests (TFTs):

- **TSH:** Suppressed (<0.05 mU/L) in hyperthyroidism due to negative feedback from high circulating thyroid hormone levels.
- **Free T4 and T3:** Elevated levels of free T4 and/or T3 confirm hyperthyroidism.

b) Thyroid Autoantibodies:

- **Thyroid-stimulating hormone receptor antibodies (TRAbs):** Elevated in **Graves' disease**, the most common cause of thyrotoxicosis.
- **Thyroid peroxidase antibodies (TPOAb):** Often elevated in autoimmune thyroid disease, including Graves' and Hashimoto's thyroiditis.

c) Radioactive Iodine Uptake Scan:

- Helps differentiate between different causes of thyrotoxicosis:
 - **High uptake** in Graves' disease and toxic multinodular goitre.
 - **Low uptake** in thyroiditis or iodine-induced thyrotoxicosis.

d) ECG:

- Used to detect **arrhythmias** such as **atrial fibrillation** or **sinus tachycardia**.

4. Explanation of Investigations:

- **TSH and Free T4/T3:** Low TSH with high free T4 and/or T3 confirms hyperthyroidism. TSH is more sensitive for diagnosing mild (subclinical) hyperthyroidism, whereas free T4/T3 levels confirm overt disease.
- **TRAbs and TPOAb:** TRAbs are specific for **Graves' disease**, helping differentiate it from other causes of thyrotoxicosis.
- **Radioactive iodine uptake scan:** Identifies the source of excess thyroid hormone production and helps guide treatment (e.g., differentiating between **Graves' disease** and **thyroiditis**).

5. Diagnosis Criteria for Thyrotoxicosis:

Thyrotoxicosis is diagnosed based on a combination of clinical symptoms and abnormal thyroid function tests:

- **Suppressed TSH** (<0.05 mU/L).
- **Elevated free T4 and/or T3** levels.
- **Positive TRAbs** indicate **Graves' disease**.

Differential diagnoses include:

- **Graves' disease:** Positive TRAbs, diffuse radioactive iodine uptake.
- **Toxic multinodular goitre:** Multiple nodules with focal high uptake on imaging.
- **Toxic adenoma:** A single nodule with high uptake.
- **Thyroiditis:** Low radioactive iodine uptake with transient thyrotoxicosis.

6. First-Line Therapy According to Guidelines:

The choice of treatment depends on the underlying cause of thyrotoxicosis, patient preference, and clinical severity.

a) Antithyroid Drugs:

- **Carbimazole** is the first-line drug in the UK:
 - **Initial dose:** 15-40 mg/day depending on the severity.

- Mechanism: Inhibits thyroid hormone synthesis by blocking thyroid peroxidase.
- Treatment duration: Typically **12-18 months** in Graves' disease to achieve remission.
- **Propylthiouracil (PTU)**: Used in **pregnancy** (first trimester) or when carbimazole is contraindicated.
 - **Dose**: 100-150 mg three times daily, titrated according to response.
 - **Black box warning**: Risk of hepatotoxicity with PTU.

b) Beta-Blockers:

- **Propranolol** (40 mg three times daily) or **atenolol** (25-50 mg once daily):
 - Used to control **symptoms** such as **palpitations**, **tremor**, and **anxiety** until the antithyroid medications take effect.

c) Radioactive Iodine Therapy:

- A **definitive treatment** for hyperthyroidism:
 - Oral dose of **radioactive iodine (I-131)**, which destroys thyroid tissue.
 - Used in **Graves' disease**, **toxic multinodular goitre**, or **toxic adenoma**.
 - **Contraindicated in pregnancy**.

d) Surgery (Thyroidectomy):

- **Total or subtotal thyroidectomy** is reserved for patients with large goitres, compressive symptoms, or when other treatments fail.
- **Indications**: Large goitres, suspicion of cancer, or patient preference.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Carbimazole** should be avoided in the **first trimester of pregnancy** due to the risk of congenital malformations (use **propylthiouracil** instead).
- **Radioactive iodine** is contraindicated in **pregnancy** and **breastfeeding**.

b) Second-Line Therapy:

1. **Thyroid Surgery**:
 - For patients who cannot tolerate medications or have failed radioactive iodine therapy.
2. **Propylthiouracil (PTU)**:
 - Used when carbimazole is contraindicated, particularly in early pregnancy.
 - May be used in cases of **thyroid storm**.

8. Routine Monitoring and Follow-Up:

1. **Thyroid Function Tests (TFTs)**:
 - After starting antithyroid drugs, recheck **TSH**, **free T4**, and **T3** levels every **4-6 weeks** to monitor response and adjust dosage.
 - After radioactive iodine therapy or surgery, monitor TFTs for **hypothyroidism**, which may develop later.
2. **Complete Blood Count (CBC)**:
 - Monitor for **agranulocytosis**, a rare but serious side effect of **carbimazole** and **PTU**. Patients should report symptoms of infection (e.g., sore throat, fever).
3. **Liver Function Tests (LFTs)**:
 - Particularly important when using **propylthiouracil** due to the risk of **hepatotoxicity**.
4. **Clinical Monitoring**:
 - Regularly assess for symptom improvement (palpitations, weight loss, etc.).

9. Complications:

a) Thyroid Storm:

- A **life-threatening emergency** due to severe, untreated or poorly controlled hyperthyroidism.
- Symptoms: **High fever, tachycardia, confusion, vomiting, diarrhoea, coma.**
- Management: **High-dose antithyroid drugs, beta-blockers, hydrocortisone,** and supportive care.

b) Cardiovascular Complications:

- **Atrial fibrillation:** Common in older patients, increasing the risk of **stroke**.
- **Heart failure:** May develop due to persistent tachycardia or arrhythmias.

c) Osteoporosis:

- Long-standing hyperthyroidism can lead to **bone resorption** and increased risk of **osteoporosis** and **fractures**.

d) Hypothyroidism:

- Can occur as a result of **radioactive iodine therapy** or **thyroid surgery**, requiring lifelong **levothyroxine replacement**.

132. Thyroid Cancer

1. Detailed Definition of Thyroid Cancer:

Thyroid cancer refers to malignant growth in the **thyroid gland**, which is located at the base of the neck. The majority of thyroid cancers are **well-differentiated** and arise from **thyroid follicular cells**. There are four main types of thyroid cancer:

- **Papillary thyroid carcinoma (PTC):** The most common type, accounting for around 70-80% of cases. It typically has an excellent prognosis.
- **Follicular thyroid carcinoma (FTC):** The second most common, comprising 10-15% of cases, more common in areas with low iodine intake.
- **Medullary thyroid carcinoma (MTC):** Arises from **parafollicular (C cells)** and is often associated with **Multiple Endocrine Neoplasia type 2 (MEN2)**.
- **Anaplastic thyroid carcinoma (ATC):** A rare but aggressive type with poor prognosis.

2. Common Presenting Complaints and Symptoms:

Thyroid cancer can often present with minimal symptoms, and it is sometimes detected incidentally during imaging for other conditions. However, presenting features may include:

- **Lump in the neck:** A painless, slowly enlarging mass or nodule is the most common symptom.
- **Hoarseness or voice changes:** Occurs if the recurrent laryngeal nerve is involved.
- **Dysphagia** (difficulty swallowing): Due to compression of the oesophagus.
- **Dyspnoea:** Due to tracheal compression by the tumour.
- **Neck pain:** Uncommon, but can occur if the tumour invades nearby structures.
- **Lymphadenopathy:** Enlarged lymph nodes in the neck, indicating possible metastasis.
- **Symptoms of hyperthyroidism or hypothyroidism:** Rare but possible in certain types of thyroid cancer.

3. First-Line Investigations:

a) Thyroid Function Tests (TFTs):

- **TSH, Free T4, and T3:** Typically normal in thyroid cancer. Thyroid cancers are usually non-functional, though some follicular carcinomas may produce thyroid hormone.

b) Ultrasound of the Thyroid:

- First-line imaging modality to assess the **size, shape, and characteristics** of thyroid nodules (e.g., solid vs cystic, calcifications, irregular margins).
- **Ultrasound-guided fine-needle aspiration (FNA)** is essential for cytological evaluation.

c) Fine-Needle Aspiration (FNA) Biopsy:

- **Gold standard** for diagnosing thyroid cancer.
- The FNA provides a sample for **cytological evaluation** to assess for malignancy (e.g., presence of cancer cells).

d) Serum Calcitonin:

- Elevated in **medullary thyroid carcinoma** as calcitonin is produced by **C cells**.

e) Thyroid-Stimulating Hormone (TSH) Suppression Test:

- Helps differentiate between benign and malignant nodules in some cases.

f) Imaging:

- **CT/MRI:** Used to evaluate the extent of tumour spread and assess lymph node involvement.
- **Radioiodine scan:** After total thyroidectomy, to detect residual thyroid tissue or metastases.

4. Explanation of Investigations:

- **Ultrasound:** Helps identify suspicious features of thyroid nodules such as irregular borders, microcalcifications, and hypoechogenicity.
- **FNA biopsy:** Provides a definitive diagnosis based on cytology, differentiating between benign and malignant nodules.
- **Calcitonin:** Marker for **medullary thyroid cancer**, used both for diagnosis and monitoring.
- **Radioiodine scan:** Useful in **well-differentiated thyroid cancers** to detect metastasis after treatment.

5. Diagnosis Criteria for Thyroid Cancer:

Thyroid cancer is diagnosed based on a combination of clinical features, imaging, and **FNA cytology** results. The **Bethesda System for Reporting Thyroid Cytopathology** is used to classify FNA results:

1. **Non-diagnostic.**
2. **Benign.**
3. **Atypia of undetermined significance.**
4. **Follicular neoplasm or suspicious for follicular neoplasm.**
5. **Suspicious for malignancy.**
6. **Malignant.**

Definitive diagnosis is made following histological examination after **surgical excision**.

6. First-Line Therapy According to Guidelines:

The treatment approach for thyroid cancer depends on the type and stage of the cancer.

a) Surgery:

- **Total thyroidectomy** is the standard treatment for **papillary, follicular, and medullary** thyroid carcinomas:
 - Removes the entire thyroid gland.
 - **Lobectomy** (removal of one lobe) may be considered for smaller, low-risk papillary cancers.

- **Lymph node dissection:** If there is evidence of nodal metastasis.

b) Radioactive Iodine Ablation (RAI):

- Used after **total thyroidectomy** in **well-differentiated cancers** (papillary and follicular) to destroy any remaining thyroid tissue and treat distant metastases.
- Contraindicated in **medullary** and **anaplastic** thyroid cancers as they do not take up iodine.

c) Thyroid Hormone Suppression Therapy:

- Following surgery, **levothyroxine** is given at a dose that suppresses **TSH** to prevent cancer recurrence.
- Aim: TSH below the reference range.

d) Chemotherapy and Radiotherapy:

- **External beam radiotherapy:** Used in **anaplastic thyroid cancer** or unresectable tumours.
- **Chemotherapy:** Reserved for advanced **anaplastic thyroid cancer** or refractory cases.

e) Targeted Therapy:

- For patients with advanced **medullary thyroid carcinoma**, **tyrosine kinase inhibitors (TKIs)** such as **vandetanib** or **cabozantinib** may be used.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Radioactive iodine** is contraindicated in **pregnancy** and **breastfeeding**.
- Use of **TKIs** may have significant side effects such as **hypertension**, **diarrhoea**, and **liver dysfunction**.

b) Second-Line Therapy:

- In cases where surgery and radioactive iodine are not effective, **systemic therapies** like **sorafenib** (a TKI) may be considered for **advanced disease**.
- **Palliative care:** For advanced **anaplastic thyroid cancer**, which has a poor prognosis.

8. Routine Monitoring and Follow-Up:

1. TSH and Free T4:

- Monitor TSH levels regularly to ensure **TSH suppression** is adequate post-surgery.
- Adjust **levothyroxine dose** based on TSH levels.

2. Thyroglobulin (Tg):

- A marker for **papillary and follicular thyroid cancer**. It should be undetectable after total thyroidectomy and radioactive iodine treatment. **Rising levels** suggest recurrence.

3. Neck Ultrasound:

- Annually to assess for **local recurrence** in the neck or metastatic lymph nodes.

4. Calcitonin and Carcinoembryonic Antigen (CEA):

- For monitoring **medullary thyroid carcinoma**. Rising calcitonin levels suggest recurrence or metastasis.

5. Radioiodine Scans:

- Performed post-operatively to detect residual or metastatic disease in **well-differentiated cancers**.

9. Complications:

a) Hypothyroidism:

- Post-thyroidectomy, patients will require lifelong **levothyroxine** replacement.

b) Recurrent Laryngeal Nerve Injury:

- A complication of thyroid surgery, leading to **hoarseness**, **voice changes**, or **vocal cord paralysis**.

c) Hypocalcaemia:

- **Accidental damage or removal of parathyroid glands** during thyroid surgery can lead to **hypocalcaemia**, requiring **calcium** and **vitamin D supplements**.

d) Metastasis:

- **Papillary thyroid cancer** can spread to **lymph nodes**.
- **Follicular thyroid cancer** tends to spread via the bloodstream to the **lungs** and **bones**.
- **Medullary thyroid cancer** can metastasise to **liver**, **bones**, and **lungs**.

Summary of Key Points for Thyroid Cancer:

- **Thyroid cancer** includes various types, with **papillary** and **follicular** cancers having the best prognosis.
- Diagnosis is based on **ultrasound**, **FNA biopsy**, and **thyroid function tests**.
- **Surgery** (total thyroidectomy) is the primary treatment, often followed by **radioactive iodine** in well-differentiated cancers.
- Post-treatment monitoring includes **TSH suppression**, **thyroglobulin levels**, and **neck ultrasound**.
- Complications include **hypothyroidism**, **nerve injury**, and **metastasis** in advanced cases.

133. Thyroid Eye Disease (TED)

1. Detailed Definition of Thyroid Eye Disease:

Thyroid eye disease (TED), also known as **Graves' orbitopathy** or **thyroid-associated ophthalmopathy**, is an autoimmune condition often associated with **Graves' disease**. It primarily affects the tissues around the eyes, leading to inflammation, swelling, and damage to muscles and connective tissues behind the eyes. TED can occur before, during, or after the diagnosis of thyroid dysfunction, and in some cases, even without any significant thyroid hormone imbalance.

TED is characterised by **proptosis (exophthalmos)**, **diplopia (double vision)**, and, in severe cases, **optic neuropathy** that can threaten vision.

2. Common Presenting Complaints and Symptoms:

Patients with **thyroid eye disease** typically present with one or more of the following symptoms:

- **Proptosis:** Forward protrusion of the eyes (exophthalmos), causing a "staring" appearance.
- **Eye irritation:** Including redness, grittiness, and dryness.
- **Diplopia:** Double vision due to muscle involvement and restriction in eye movements.
- **Photophobia:** Sensitivity to light.
- **Excessive tearing or watery eyes.**
- **Eye pain:** Often exacerbated by eye movement.
- **Swollen eyelids:** Puffiness around the eyes.
- **Blurring or loss of vision:** In severe cases, particularly if the optic nerve is compressed.

- **Lid retraction:** The upper eyelid may appear higher than normal, exposing more of the white of the eye (sclera).

3. First-Line Investigations:

a) Thyroid Function Tests (TFTs):

- **TSH, Free T4, and T3:** These tests help to assess the thyroid function. TED is often associated with **hyperthyroidism** (Graves' disease), though it can also occur in patients with **euthyroid** or **hypothyroid states**.

b) Thyroid Autoantibodies:

- **Thyroid-stimulating hormone receptor antibodies (TRAbs):** These are typically elevated in **Graves' disease** and are associated with TED.
- **Thyroid peroxidase antibodies (TPOAb):** May be elevated in autoimmune thyroid conditions.

c) Orbital Imaging:

- **CT or MRI scan of the orbits:** These imaging techniques help assess the extent of **orbital tissue involvement**, particularly the **extraocular muscles** and soft tissues. MRI is preferred for detecting **optic nerve compression**.

d) Visual Acuity and Visual Field Testing:

- To assess for any **loss of vision** or field defects, particularly in cases where there is concern for **optic neuropathy**.

e) Hertel Exophthalmometry:

- This is used to measure the **degree of proptosis** (eye protrusion) and monitor its progression over time.

4. Explanation of Investigations:

- **TFTs and antibodies:** Thyroid function tests and autoantibodies are crucial in determining the underlying thyroid status and confirming an association with **Graves' disease**.
- **Orbital imaging:** Helps to visualise the extent of orbital inflammation and to rule out compressive lesions affecting the **optic nerve**.
- **Visual acuity testing:** Critical in monitoring for potential complications such as **optic neuropathy**, which can cause vision loss if untreated.
- **Exophthalmometry:** Measures the severity of **proptosis**, helping to track disease progression.

5. Diagnosis Criteria for Thyroid Eye Disease:

TED is diagnosed based on a combination of clinical findings, thyroid function tests, and imaging results. Diagnostic criteria include:

- **Proptosis:** Detected clinically or through exophthalmometry.
- **Signs of inflammation:** Including periorbital swelling, erythema, conjunctival injection, and chemosis.
- **Restrictive myopathy:** Leading to limited extraocular movements and **diplopia**.
- **Optic nerve involvement:** Indicated by **decreased visual acuity, colour vision impairment, or visual field defects**.
- **History of thyroid disease:** Typically associated with **Graves' disease**, though it can also occur in other thyroid disorders or euthyroid states.

6. First-Line Therapy According to Guidelines:

The management of TED involves controlling both the **underlying thyroid disease** and the **eye disease** itself.

a) Thyroid Management:

- **Euthyroidism** should be maintained by managing **thyroid function** appropriately (e.g., using antithyroid drugs, radioactive iodine, or thyroidectomy).

In patients with **Graves' disease**, treatment of hyperthyroidism with **radioactive iodine** may worsen eye symptoms, so corticosteroids may be given concurrently to reduce the risk.

b) Supportive Eye Care:

- **Lubricating eye drops** (artificial tears) and **ointments** to relieve **dry eyes** and irritation.
- **Sunglasses**: To reduce **photophobia** and protect against **light sensitivity**.
- **Sleeping with the head elevated**: Can help reduce **periorbital swelling**.

c) Corticosteroids:

- **High-dose systemic corticosteroids** (e.g., **prednisolone 40-80 mg/day**) are used for severe or active inflammatory TED, particularly in cases of **optic nerve compression**.
- Steroids are often given intravenously in more severe cases (e.g., **methylprednisolone** pulses) and tapered according to response.

d) Radiotherapy:

- **Orbital radiotherapy** can be used to reduce inflammation and fibrosis in the eye muscles and soft tissues, especially in patients who do not respond to steroids.

e) Immunosuppressive Therapy:

- **Biologic agents**: Newer treatments include **teprotumumab**, an insulin-like growth factor-1 receptor (IGF-1R) inhibitor, which has shown promise in reducing the severity of TED.
- **Other immunosuppressants**: Such as **rituximab** may be considered in refractory cases.

f) Surgery:

- **Orbital decompression surgery**: For severe proptosis or when **optic neuropathy** is present. This procedure removes bone or fat from the orbit to reduce the pressure on the optic nerve.
- **Strabismus surgery**: To correct **diplopia** by aligning the eye muscles.
- **Eyelid surgery**: For **eyelid retraction** or cosmetic improvement.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Systemic corticosteroids** may not be suitable for long-term use due to side effects such as **osteoporosis**, **hypertension**, and **hyperglycaemia**.
- **Orbital radiotherapy** is contraindicated in younger patients (<35 years) due to concerns about radiation exposure leading to secondary malignancies.

b) Second-Line Therapy:

- **Teprotumumab**: A second-line treatment option in patients who do not respond to steroids or have contraindications to other therapies.
- **Surgical intervention**: For refractory cases or when conservative measures fail.

8. Routine Monitoring and Follow-Up:

1. Thyroid Function Monitoring:

- Regularly monitor thyroid function (TSH, Free T4, Free T3) to maintain **euthyroidism**.

2. Eye Examinations:

- Follow up every **3-6 months** during active TED to monitor for progression or improvement in symptoms, proptosis, and visual acuity.
- 3. Orbital Imaging:**
 - Repeat **MRI** or **CT** scans if there is concern for worsening eye disease or development of optic nerve compression.
 - 4. Visual Acuity and Field Testing:**
 - Regular monitoring of visual acuity and **visual fields** is necessary to detect early optic nerve involvement.

9. Complications:

a) Optic Neuropathy:

- A serious complication of TED where compression of the optic nerve leads to **vision loss** if not treated promptly.
- Symptoms include **blurred vision**, **colour desaturation**, and **visual field defects**.

b) Corneal Exposure and Ulceration:

- Severe **proptosis** or **lid retraction** may result in **incomplete eyelid closure**, leading to **corneal exposure**, **drying**, and **ulceration**.

c) Diplopia:

- Restrictive myopathy can lead to permanent **double vision** due to fibrosis of the extraocular muscles.

d) Cosmetic Concerns:

- Significant **exophthalmos**, **lid retraction**, or **strabismus** may cause psychological distress due to changes in appearance.

Summary of Key Points for Thyroid Eye Disease:

- **Thyroid eye disease (TED)** is an autoimmune condition often associated with **Graves' disease**, leading to inflammation and swelling around the eyes, causing **proptosis**, **diplopia**, and, in severe cases, **optic neuropathy**.
- Investigations include **thyroid function tests**, **orbital imaging**, and **visual acuity testing**.

134. Thyroid Nodules

1. Detailed Definition of Thyroid Nodules:

Thyroid nodules are discrete lumps within the thyroid gland, which can be either **solid** or **cystic**. They are common in the general population, especially in women and older adults. Most thyroid nodules are **benign**, but a small percentage (~5-10%) may represent **thyroid cancer**. Thyroid nodules can be single (solitary) or multiple (multinodular goitre).

2. Common Presenting Complaints and Symptoms:

Most thyroid nodules are **asymptomatic** and are often discovered incidentally during imaging for other reasons or a routine physical examination. However, some nodules may present with:

- **Palpable lump in the neck:** The most common presenting feature.
- **Dysphagia:** Difficulty swallowing, especially if the nodule is large or compresses the oesophagus.
- **Dyspnoea:** Difficulty breathing due to tracheal compression.
- **Hoarseness:** If the nodule affects the recurrent laryngeal nerve.
- **Pain or tenderness:** Rarely, a thyroid nodule may become painful, particularly if there is associated haemorrhage or inflammation.

- **Symptoms of hyperthyroidism:** In cases of **toxic thyroid nodules** (autonomously functioning nodules), patients may have **palpitations, weight loss, and heat intolerance**.
- **Hypothyroid symptoms:** If the nodule is associated with **Hashimoto's thyroiditis**, patients may present with **fatigue, cold intolerance, and weight gain**.

3. First-Line Investigations:

a) Thyroid Function Tests (TFTs):

- **TSH, Free T4, Free T3:** Thyroid function tests help determine if the nodule is affecting **thyroid hormone production**.
 - **Normal TSH:** Suggests a non-functional (cold) nodule, which may have a higher risk of malignancy.
 - **Low TSH:** Suggests a **hyperfunctioning (toxic)** nodule, which is usually benign.
 - **High TSH:** May indicate **Hashimoto's thyroiditis**.

b) Ultrasound of the Thyroid:

- The **first-line imaging investigation** for characterising thyroid nodules.
- Ultrasound helps assess:
 - **Size and number** of nodules.
 - **Echogenicity:** Hypoechoic nodules are more suspicious.
 - **Margins:** Irregular or blurred margins may indicate malignancy.
 - **Microcalcifications:** Associated with a higher risk of malignancy.
 - **Vascularity:** Increased blood flow within the nodule may raise suspicion for cancer.

c) Fine-Needle Aspiration (FNA) Biopsy:

- The **gold standard** for evaluating thyroid nodules.
- **FNA** is used to assess cytology and differentiate between benign and malignant nodules.
- Results are classified according to the **Bethesda system**, ranging from benign (Category II) to malignant (Category VI).

d) Radionuclide Thyroid Scan:

- **Iodine-123 or Technetium-99m** is used to evaluate **nodule function**.
 - **Hot nodule:** Increased uptake of radioactive iodine, usually benign and often associated with hyperthyroidism.
 - **Cold nodule:** No uptake of iodine, which has a higher risk of being malignant.

4. Explanation of Investigations:

- **Thyroid Function Tests:** Abnormal results can help guide the management of nodules. For example, a low TSH might suggest a hyperfunctioning nodule, which is typically benign.
- **Ultrasound:** Identifies suspicious features like **hypoechogenicity, irregular margins, or microcalcifications** that may indicate malignancy.
- **FNA biopsy:** Differentiates benign from malignant nodules based on cytology. The **Bethesda system** helps to guide further management.
- **Radionuclide scan:** Helps assess whether a nodule is producing thyroid hormone independently ("hot") or is non-functional ("cold").

5. Diagnosis Criteria for Thyroid Nodules:

The diagnosis of a **thyroid nodule** is confirmed based on the presence of a palpable lump in the thyroid gland or via **ultrasound**. The risk of malignancy is assessed using:

- **Thyroid ultrasound** features (hypoechoogenicity, irregular margins, microcalcifications).
- **Cytology** from FNA biopsy, reported using the Bethesda system.

Nodules classified as **Bethesda Category II (benign)** require no further immediate investigation but should be followed up. Nodules with **Bethesda III or higher** (suspicious or malignant features) may require further management, including surgery.

6. First-Line Therapy According to Guidelines:

Management depends on the size, symptoms, and cytological findings of the thyroid nodule.

a) Benign Nodules (Bethesda II):

- **Conservative management:** Most benign nodules can be monitored with **regular ultrasound** and clinical review, especially if asymptomatic.
- **Levothyroxine suppression therapy:** Not routinely recommended but may be considered for **benign, large nodules** to reduce their size.

b) Suspicious or Malignant Nodules (Bethesda III-VI):

- **Surgery** is the mainstay of treatment for nodules that are either malignant or highly suspicious for malignancy.
 - **Lobectomy:** Removal of one thyroid lobe, may be sufficient for small, low-risk papillary carcinomas.
 - **Total thyroidectomy:** Recommended for larger nodules, malignant nodules, or when there is suspicion of metastatic disease.

c) Toxic Nodules:

- **Radioactive iodine (I-131)** is commonly used to treat **autonomously functioning nodules** or **toxic multinodular goitres**, as it selectively destroys hyperfunctioning thyroid tissue.
- **Surgery:** May be indicated for large toxic nodules or multinodular goitres causing compressive symptoms.
- **Antithyroid drugs:** Such as **carbimazole** or **propylthiouracil**, may be used to control hyperthyroidism while preparing for definitive therapy.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Surgery** may be contraindicated in patients with significant comorbidities who are not fit for anaesthesia. Alternative treatments include **radioactive iodine** for hyperfunctioning nodules.
- **Radioactive iodine therapy** is contraindicated in **pregnant** or **breastfeeding women** and patients planning pregnancy within 6 months.

b) Second-Line Therapy:

- For patients not suitable for surgery, **radiofrequency ablation** or **ethanol ablation** can be used as a **minimally invasive** approach to reduce nodule size.
- **Radioactive iodine** may be used to manage **hyperfunctioning** nodules in patients not suitable for surgery.

8. Routine Monitoring and Follow-Up:

1. Thyroid Ultrasound:

- Follow-up ultrasound is recommended **6-12 months** after the initial assessment for nodules that are benign or indeterminate.

- Nodules that increase in size or develop suspicious features should be reassessed with FNA.
- 2. **Thyroid Function Tests:**
 - Repeat TFTs to monitor **thyroid function**, particularly in patients with toxic nodules or after radioactive iodine treatment.
- 3. **Clinical Examination:**
 - Regular clinical follow-up to assess for the development of new symptoms (e.g., compressive symptoms, voice changes).

9. Complications:

a) Malignancy:

- Although most thyroid nodules are benign, a small percentage may represent **thyroid cancer**. Early detection and treatment are crucial to avoid the spread of disease.

b) Hyperthyroidism:

- **Toxic thyroid nodules** can lead to **thyrotoxicosis**, resulting in palpitations, weight loss, and heat intolerance.

c) Compression Symptoms:

- Large nodules or multinodular goitres can cause **dysphagia**, **dyspnoea**, or **hoarseness** if they compress the oesophagus, trachea, or recurrent laryngeal nerve.

d) Post-Surgical Complications:

- **Hypocalcaemia:** Occurs if the parathyroid glands are inadvertently removed or damaged during thyroidectomy.
- **Recurrent laryngeal nerve injury:** Leading to **hoarseness** or **voice changes**.

Summary of Key Points for Thyroid Nodules:

- **Thyroid nodules** are common and usually benign, though a small percentage may be malignant.
- The initial evaluation includes **thyroid ultrasound**, **FNA biopsy**, and **thyroid function tests**.
- Management depends on the size, symptoms, and cytological findings, with surgery or **radioactive iodine** reserved for suspicious or hyperfunctioning nodules.
- **Regular monitoring** with ultrasound is crucial for benign or indeterminate nodules to detect any changes over time.

135. Addison's Disease

1. Detailed Definition of Addison's Disease:

Addison's disease, also known as **primary adrenal insufficiency**, is a rare condition in which the **adrenal glands** fail to produce adequate amounts of **cortisol** and, in most cases, **aldosterone**. It is primarily caused by the destruction of the adrenal cortex, often due to an autoimmune process, but can also be secondary to infections, metastatic disease, or other factors.

2. Common Presenting Complaints and Symptoms:

The clinical presentation of Addison's disease is often **insidious** and non-specific, which can lead to delayed diagnosis. Symptoms often worsen during periods of **stress** (e.g., infections or surgery).

Common symptoms include:

- **Fatigue and weakness:** Progressive, generalised fatigue.

- **Weight loss:** Unintentional and progressive weight loss.
- **Hyperpigmentation:** Darkening of the skin, especially in areas exposed to friction (e.g., elbows, knees) and mucous membranes.
- **Hypotension:** Postural dizziness and low blood pressure.
- **Nausea, vomiting, and abdominal pain.**
- **Salt cravings:** Due to aldosterone deficiency and salt loss.
- **Anorexia:** Loss of appetite.
- **Hypoglycaemia:** Episodes of low blood sugar, more common in children.
- **Depression or irritability:** Mental health symptoms can be subtle but present.

3. First-Line Investigations:

a) Blood Tests:

- **Cortisol levels:** Low morning cortisol (<100 nmol/L) is suggestive of adrenal insufficiency.
- **ACTH (Adrenocorticotrophic hormone):** Elevated ACTH in Addison's disease due to a lack of negative feedback from cortisol.

b) Synacthen Stimulation Test (ACTH Stimulation Test):

- The **gold standard** test for diagnosing Addison's disease.
- A baseline cortisol level is measured, then **synthetic ACTH (Synacthen)** is administered. Failure of the cortisol to rise sufficiently after ACTH administration confirms the diagnosis.
 - **Normal response:** A cortisol increase > 500 nmol/L 30 minutes after the injection.
 - **Addison's disease:** Little or no increase in cortisol after Synacthen.

c) Electrolytes:

- **Hyponatraemia** (low sodium) and **hyperkalaemia** (high potassium) are common due to aldosterone deficiency.
- **Hypoglycaemia** can also be seen.

d) Plasma Renin and Aldosterone Levels:

- **High plasma renin** and **low aldosterone** confirm **mineralocorticoid deficiency**, which is typical in Addison's disease.

e) Autoantibodies:

- **21-hydroxylase antibodies:** These are present in the majority of patients with autoimmune Addison's disease.

4. Explanation of Investigations:

- **Cortisol:** A low baseline cortisol level indicates adrenal insufficiency, but a Synacthen stimulation test is needed to confirm the diagnosis.
- **ACTH:** Elevated ACTH indicates primary adrenal insufficiency as the pituitary gland tries to compensate for low cortisol.
- **Synacthen test:** The absence of a cortisol rise after ACTH stimulation is diagnostic of Addison's disease.
- **Electrolytes:** Hyponatraemia and hyperkalaemia reflect aldosterone deficiency, which causes salt wasting and potassium retention.

5. Diagnosis Criteria for Addison's Disease:

The diagnosis of Addison's disease is confirmed with:

- **Low baseline cortisol** levels.

- **High ACTH** levels.
- **Failed response** to the **Synacthen stimulation test** (cortisol fails to rise appropriately).
- **Electrolyte imbalances** (e.g., hyponatraemia, hyperkalaemia).
- **Presence of adrenal autoantibodies** (in autoimmune cases).

6. First-Line Therapy According to Guidelines:

a) Corticosteroid Replacement:

- **Hydrocortisone** is the first-line treatment for cortisol replacement:
 - **Dose:** 15-30 mg daily, divided into two or three doses.
 - The highest dose is typically given in the morning to mimic the natural diurnal rhythm of cortisol secretion.
- **Prednisolone** or **dexamethasone** may be used as alternatives but are less common.

b) Mineralocorticoid Replacement:

- **Fludrocortisone** is used to replace aldosterone:
 - **Dose:** 50-200 mcg once daily, titrated based on blood pressure, sodium, and potassium levels.
 - Helps to manage **salt and water balance** and **blood pressure**.

c) Salt Supplementation:

- In cases of significant salt wasting, particularly during illness or in hot weather, **salt tablets** or increased dietary sodium may be recommended.

d) Patient Education:

- Patients must be educated on **dose adjustment** during periods of stress (illness, surgery) to prevent **adrenal crises**:
 - **Sick day rules:** Double or triple the dose of hydrocortisone during minor illnesses.
 - Emergency **intramuscular hydrocortisone** should be available for patients in case of severe illness or vomiting.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- Long-term steroid use may have side effects, such as **osteoporosis**, **weight gain**, and **diabetes**, but it is a necessary therapy in Addison's disease.
- **Fludrocortisone** may cause **hypertension** or **fluid retention** if over-replaced.

b) Second-Line Therapy:

- **DHEA (dehydroepiandrosterone)** supplementation: May be considered for patients, particularly women, with **adrenal androgen insufficiency** causing fatigue or low mood.
- **Prednisolone** or **dexamethasone**: May be used if hydrocortisone is poorly tolerated or adherence is difficult.

8. Routine Monitoring and Follow-Up:

1. Cortisol and ACTH Levels:

- Regular monitoring of **cortisol** and **ACTH** is not usually required, but clinical response to treatment is the mainstay of monitoring.

2. Electrolytes:

- Regular monitoring of **sodium**, **potassium**, and **renin** to adjust the **fludrocortisone dose**.

3. Bone Density Monitoring:

- Given the long-term use of steroids, patients should be monitored for **osteoporosis** using **DEXA scans**.
4. **Patient Monitoring for Adrenal Crisis:**
- Education on recognising **adrenal crisis** and adjusting medications during illness is essential.
 - Ensure the patient has access to **emergency hydrocortisone injections**.

9. Complications:

a) Adrenal Crisis (Addisonian Crisis):

- A life-threatening emergency caused by **acute adrenal insufficiency**, typically triggered by illness, surgery, or stress.
- Symptoms include **severe hypotension, vomiting, dehydration, and hypoglycaemia**.
- Treatment involves **IV hydrocortisone** and aggressive fluid resuscitation with **0.9% saline**.

b) Hyponatraemia and Hyperkalaemia:

- Persistent electrolyte imbalances due to insufficient **mineralocorticoid replacement** can lead to **weakness, fatigue, and arrhythmias**.

c) Hypoglycaemia:

- Particularly common in children with Addison's disease, causing **sweating, confusion, and seizures** if untreated.

d) Osteoporosis:

- Long-term steroid use can lead to **bone density loss**, necessitating regular monitoring and **calcium/vitamin D supplementation**.

Summary of Key Points for Addison's Disease:

- **Addison's disease** is an autoimmune or infectious condition leading to **adrenal insufficiency** and deficiency of **cortisol** and **aldosterone**.
- Diagnosis is confirmed by **low cortisol, high ACTH**, and a poor response to the **Synacthen stimulation test**.
- **Hydrocortisone** and **fludrocortisone** are the cornerstone of treatment.
- Patients need lifelong **steroid replacement** and education on how to manage **adrenal crises**. Regular monitoring of **electrolytes, bone density**, and overall clinical status is essential.

136. Cushing's Syndrome

1. Detailed Definition of Cushing's Syndrome:

Cushing's syndrome refers to the clinical state caused by **chronic exposure to excess glucocorticoids**, particularly **cortisol**. It can be due to **endogenous** causes, such as overproduction of cortisol by the adrenal glands, or **exogenous** causes, such as long-term use of corticosteroid medications.

Cushing's syndrome is broadly divided into:

- **ACTH-dependent:** Due to excess **adrenocorticotrophic hormone (ACTH)**, leading to adrenal hyperplasia and cortisol overproduction (e.g., **Cushing's disease** caused by a **pituitary adenoma**).
- **ACTH-independent:** Direct overproduction of cortisol by the adrenal glands (e.g., **adrenal adenoma** or **carcinoma**).

2. Common Presenting Complaints and Symptoms:

Patients with Cushing's syndrome often present with a variety of **gradual onset** symptoms related to **cortisol excess**:

- **Weight gain**: Particularly **central obesity** with sparing of the limbs.
- **Moon face**: A rounded, full face.
- **Buffalo hump**: Accumulation of fat on the upper back and neck.
- **Proximal muscle weakness**: Difficulty climbing stairs or standing from a seated position.
- **Hypertension**.
- **Skin changes**: Including **thin skin**, **easy bruising**, **purple striae** (particularly on the abdomen), and **acne**.
- **Hirsutism**: Excessive facial and body hair, especially in women.
- **Menstrual irregularities**: Including amenorrhoea.
- **Mood disturbances**: Such as **depression**, **anxiety**, and **irritability**.
- **Osteoporosis**: Leading to fractures.
- **Glucose intolerance or diabetes mellitus**.
- **Poor wound healing**: Due to immunosuppression.

3. First-Line Investigations:

The diagnosis of Cushing's syndrome is made by demonstrating **excess cortisol** and determining its cause.

a) 24-Hour Urinary Free Cortisol:

- Measures the amount of cortisol excreted in the urine over 24 hours.
- **Elevated levels** confirm **hypercortisolism**.

b) Low-Dose Dexamethasone Suppression Test:

- A **screening test** to diagnose Cushing's syndrome.
- In normal individuals, **low-dose dexamethasone** (1 mg) suppresses cortisol production by negative feedback.
 - **Normal response**: Cortisol suppressed to < 50 nmol/L.
 - **Cushing's syndrome**: Cortisol is **not suppressed** (remains elevated).

c) Late-Night Salivary Cortisol:

- Measures cortisol levels in **saliva** at midnight.
- Elevated levels indicate loss of the normal circadian rhythm of cortisol, suggestive of Cushing's syndrome.

d) Plasma ACTH:

- **ACTH levels** help differentiate between **ACTH-dependent** (high ACTH, e.g., Cushing's disease) and **ACTH-independent** causes (low ACTH, e.g., adrenal tumour).

e) High-Dose Dexamethasone Suppression Test:

- Helps to **differentiate** between **Cushing's disease** (pituitary source of ACTH) and **ectopic ACTH secretion**.
 - **Cushing's disease**: High doses of dexamethasone suppress cortisol.
 - **Ectopic ACTH secretion**: Cortisol remains unsuppressed.

f) Imaging:

- **MRI of the pituitary**: To detect a pituitary adenoma in suspected **Cushing's disease**.
- **CT/MRI of the adrenals**: To assess for adrenal tumours in ACTH-independent causes.
- **CT chest/abdomen**: To search for ectopic ACTH-secreting tumours (e.g., small-cell lung carcinoma).

4. Explanation of Investigations:

- **24-hour urinary free cortisol:** A simple and reliable test to detect excess cortisol production.
- **Low-dose dexamethasone suppression test:** Helps confirm the diagnosis by assessing if cortisol secretion can be suppressed.
- **Plasma ACTH:** Differentiates between **ACTH-dependent** and **ACTH-independent** Cushing's syndrome.
- **High-dose dexamethasone test:** Distinguishes between a **pituitary adenoma** and **ectopic ACTH secretion**.

5. Diagnosis Criteria for Cushing's Syndrome:

Cushing's syndrome is diagnosed based on the following:

1. **Confirmed hypercortisolism:**
 - Elevated 24-hour urinary free cortisol.
 - Failure to suppress cortisol with a low-dose dexamethasone suppression test.
2. **ACTH levels:**
 - **ACTH-dependent:** Elevated ACTH in Cushing's disease or ectopic ACTH production.
 - **ACTH-independent:** Low ACTH levels in adrenal causes (e.g., adrenal adenoma or carcinoma).
3. **Imaging:**
 - **Pituitary MRI** for Cushing's disease.
 - **Adrenal imaging** (CT/MRI) for ACTH-independent causes.
 - **Chest or abdominal imaging** for ectopic ACTH secretion.

6. First-Line Therapy According to Guidelines:

a) ACTH-Dependent Cushing's Disease:

- **Transsphenoidal surgery:** Removal of the pituitary adenoma is the first-line treatment for **Cushing's disease**.
- If surgery is unsuccessful or contraindicated:
 - **Radiotherapy** to the pituitary.
 - **Medical therapy** with drugs such as **ketoconazole** (blocks cortisol synthesis) or **pasireotide** (a somatostatin analogue).

b) ACTH-Independent Causes (Adrenal Tumours):

- **Adrenalectomy:** Surgical removal of the adrenal tumour is the treatment of choice for **adrenal adenomas** and **carcinomas**.
 - **Unilateral adrenalectomy** for benign tumours.
 - **Bilateral adrenalectomy** may be necessary in rare cases of bilateral adrenal hyperplasia.

c) Ectopic ACTH Secretion:

- **Resection** of the ectopic tumour if identified (e.g., small-cell lung carcinoma).
- **Medical therapy** with **ketoconazole** or **metyrapone** to control cortisol levels if the tumour is not resectable.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Surgery** may be contraindicated in patients with significant comorbidities.
- **Radiotherapy:** Contraindicated in young patients due to the risk of hypopituitarism.

b) Second-Line Therapy:

- **Medical therapy:**
 - **Ketoconazole, metyrapone, or mitotane** are used to control cortisol production if surgery or radiotherapy is not an option.
 - **Pasireotide** can be considered in patients with **Cushing's disease** when surgery is not feasible or unsuccessful.

8. Routine Monitoring and Follow-Up:

1. **Post-Surgical Monitoring:**
 - **Cortisol levels** are measured post-surgery to confirm remission.
 - **ACTH** and **morning cortisol** are monitored to detect recurrence.
2. **Long-Term Monitoring:**
 - Regular follow-up to assess for **recurrence** or **complications** such as **diabetes, hypertension, and osteoporosis**.
3. **Monitoring for Hypopituitarism:**
 - Patients who undergo pituitary surgery or radiotherapy need monitoring for **pituitary hormone deficiencies**.

9. Complications:

a) Cardiovascular Complications:

- **Hypertension, diabetes, and hyperlipidaemia** are common in Cushing's syndrome and increase the risk of **cardiovascular disease**.

b) Osteoporosis:

- Chronic cortisol excess leads to **bone demineralisation**, increasing the risk of **fractures**.

c) Infections:

- **Cortisol-induced immunosuppression** increases the risk of infections.

d) Adrenal Insufficiency:

- Post-surgical patients are at risk of **adrenal insufficiency** and may require lifelong **glucocorticoid replacement** if adrenal glands or pituitary function are significantly impaired.

e) Recurrence:

- Cushing's syndrome can recur, especially after **incomplete tumour resection** or **radiotherapy** failure.

Summary of Key Points for Cushing's Syndrome:

- **Cushing's syndrome** is caused by chronic **cortisol excess** and can result from ACTH-dependent (pituitary adenoma, ectopic ACTH) or ACTH-independent causes (adrenal adenoma, carcinoma).
- **Symptoms** include **central obesity, moon face, hypertension, proximal muscle weakness, skin changes, and osteoporosis**.
- **First-line investigations** include the **24-hour urinary cortisol, low-dose dexamethasone suppression test, and ACTH levels**.

137. Conn's Syndrome (Primary Hyperaldosteronism)

1. Detailed Definition of Conn's Syndrome:

Conn's syndrome, also known as **primary hyperaldosteronism**, is an endocrine disorder characterised by the excessive production of **aldosterone** from the adrenal glands, leading to **hypertension** and **hypokalaemia**. The condition is usually caused by either an **aldosterone-producing adrenal adenoma** (Conn's adenoma) or **bilateral adrenal hyperplasia**. Aldosterone

increases sodium reabsorption in the kidneys, leading to increased blood pressure and potassium excretion.

2. Common Presenting Complaints and Symptoms:

Patients with Conn's syndrome may present with the following:

- **Hypertension:** Often resistant to standard treatment and typically diagnosed at a young age.
- **Hypokalaemia:** Low potassium levels, which may present with:
 - **Muscle weakness or cramps.**
 - **Fatigue.**
 - **Numbness or tingling** (paraesthesia).
 - **Palpitations or arrhythmias.**
 - **Polyuria** (increased urination) and **polydipsia** (increased thirst), due to potassium depletion.
- **Headaches.**
- **Nocturia:** Due to electrolyte disturbances.
- **Metabolic alkalosis:** Increased bicarbonate levels in the blood secondary to potassium loss.

Many patients are **asymptomatic** and diagnosed during evaluation for **hypertension** or **hypokalaemia** on routine blood tests.

3. First-Line Investigations:

a) Serum Electrolytes:

- **Hypokalaemia:** Potassium levels are typically low (< 3.5 mmol/L).
- **Serum sodium:** May be mildly elevated due to increased sodium reabsorption.
- **Metabolic alkalosis:** Elevated bicarbonate levels may be present as a result of potassium and hydrogen ion loss.

b) Plasma Aldosterone and Renin Levels:

- **Aldosterone:** Elevated in Conn's syndrome.
- **Plasma renin activity (PRA):** Suppressed due to the negative feedback from high aldosterone levels.
- **Aldosterone-to-renin ratio (ARR):** This is the most important screening test. A **high ARR** (typically > 20) suggests primary hyperaldosteronism.

c) Salt Loading Test (Confirmatory Test):

- After the initial screening with ARR, a **salt loading test** can be performed to confirm the diagnosis:
 - **Oral or intravenous sodium loading** is given, and aldosterone levels are measured. In Conn's syndrome, aldosterone remains elevated despite high sodium intake (normally aldosterone should be suppressed).

d) Adrenal Imaging (CT or MRI):

- **CT or MRI of the adrenal glands** is performed to distinguish between **unilateral adrenal adenoma** (Conn's adenoma) and **bilateral adrenal hyperplasia**.

e) Adrenal Vein Sampling:

- If imaging shows **bilateral adrenal enlargement** or inconclusive results, **adrenal vein sampling** may be required to differentiate unilateral from bilateral disease and guide surgical treatment. It involves measuring aldosterone levels from both adrenal veins.

4. Explanation of Investigations:

- **Aldosterone-to-renin ratio (ARR):** A high ratio is diagnostic of primary hyperaldosteronism. In secondary hyperaldosteronism (e.g., heart failure), both renin and aldosterone would be elevated.
- **Salt loading test:** Confirms autonomous aldosterone production in Conn's syndrome by failing to suppress aldosterone even in the presence of high sodium.
- **CT/MRI:** Helps detect adrenal adenomas or hyperplasia.
- **Adrenal vein sampling:** Confirms whether the aldosterone excess is unilateral (adenoma) or bilateral (hyperplasia).

5. Diagnosis Criteria for Conn's Syndrome:

Diagnosis of **Conn's syndrome** is confirmed based on:

1. **Elevated aldosterone** levels.
2. **Suppressed plasma renin** levels.
3. **High aldosterone-to-renin ratio (ARR).**
4. **Failure of aldosterone suppression** in the salt loading test.
5. Imaging (CT or MRI) demonstrating an adrenal adenoma or hyperplasia.

6. First-Line Therapy According to Guidelines:

a) Unilateral Aldosterone-Producing Adenoma (Conn's Adenoma):

- **Surgical removal (adrenalectomy)** is the first-line treatment for patients with a confirmed unilateral adrenal adenoma.
 - Surgery often **cures hypertension** or significantly reduces the need for antihypertensive medications.
 - **Potassium levels** usually normalise after surgery.

b) Bilateral Adrenal Hyperplasia:

- **Medical management** is preferred for bilateral disease.
- **Aldosterone antagonists** (mineralocorticoid receptor antagonists), such as:
 - **Spironolactone** (50-200 mg daily): First-line treatment. Spironolactone blocks the action of aldosterone on the kidneys, reducing sodium reabsorption and increasing potassium retention.
 - **Eplerenone** (25-100 mg daily): Used as an alternative to spironolactone in patients who experience side effects (e.g., gynaecomastia or menstrual disturbances), as it is more selective for aldosterone receptors.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Spironolactone** is contraindicated in patients with **severe renal impairment** or **hyperkalaemia**.
- **Eplerenone** may be used as a second-line option due to fewer side effects but is contraindicated in similar conditions.

b) Second-Line Therapy:

- **Amiloride:** A **potassium-sparing diuretic** may be used as a second-line treatment for patients who cannot tolerate **spironolactone** or **eplerenone**.

8. Routine Monitoring and Follow-Up:

1. **Blood Pressure Monitoring:**
 - Regular **blood pressure checks** to ensure adequate control post-surgery or on medical management.

2. Serum Potassium and Electrolytes:

- Regular monitoring of **potassium** levels, especially in patients on **aldosterone antagonists**, to prevent **hyperkalaemia** or **hypokalaemia**.

3. Renal Function:

- Monitor **serum creatinine** and **eGFR** regularly, as aldosterone antagonists can affect renal function.

4. Repeat Imaging:

- Post-surgery or in patients with bilateral adrenal hyperplasia, follow-up **imaging** may be required to monitor for recurrence or changes in the adrenal glands.

9. Complications:

a) Cardiovascular Complications:

- Long-term **uncontrolled hypertension** due to Conn's syndrome increases the risk of **stroke**, **myocardial infarction**, **heart failure**, and **chronic kidney disease**.

b) Hypokalaemia:

- Persistent **hypokalaemia** can lead to **arrhythmias**, **muscle weakness**, and **paralysis** if untreated.

c) Hyperkalaemia:

- Patients treated with **aldosterone antagonists** are at risk of **hyperkalaemia**, which can lead to life-threatening arrhythmias.

d) Renal Impairment:

- **Long-term hypertension** and hypokalaemia can contribute to **chronic kidney disease** and **renal impairment**.

Summary of Key Points for Conn's Syndrome:

- **Conn's syndrome** (primary hyperaldosteronism) is caused by excessive aldosterone production, leading to **hypertension** and **hypokalaemia**.
- **First-line investigations** include measuring **aldosterone-to-renin ratio (ARR)**, followed by confirmatory tests such as the **salt loading test** and **adrenal imaging**.
- **Surgical removal** (adrenalectomy) is the treatment of choice for unilateral adrenal adenomas, while **aldosterone antagonists** (e.g., spironolactone, eplerenone) are used to manage bilateral adrenal hyperplasia.
- Regular monitoring of **blood pressure**, **potassium levels**, and **renal function** is essential to prevent complications.

138. Cushing's Disease

1. Detailed Definition of Cushing's Disease:

Cushing's disease refers specifically to **Cushing's syndrome** caused by a **pituitary adenoma** that secretes excess **adrenocorticotrophic hormone (ACTH)**, which in turn stimulates the adrenal glands to produce excessive amounts of **cortisol**. It is the most common cause of **endogenous Cushing's syndrome**.

Cushing's disease is a subset of **Cushing's syndrome** (which refers to all causes of excess cortisol, including exogenous steroids or adrenal adenomas).

2. Common Presenting Complaints and Symptoms:

Patients with Cushing's disease often present with a combination of **gradual onset** symptoms related to cortisol excess:

- **Weight gain**: Particularly **central obesity** with sparing of the limbs.

- **Moon face:** A rounded, full face.
- **Buffalo hump:** Fat accumulation on the upper back and neck.
- **Proximal muscle weakness:** Difficulty climbing stairs or standing from a seated position.
- **Hypertension.**
- **Skin changes:**
 - **Thin skin.**
 - **Easy bruising.**
 - **Purple striae** (stretch marks), particularly on the abdomen.
 - **Acne.**
- **Hirsutism:** Excess facial and body hair, especially in women.
- **Menstrual irregularities:** Including amenorrhoea or oligomenorrhoea.
- **Mood changes:** Depression, anxiety, irritability, or cognitive decline.
- **Osteoporosis:** Increased risk of fractures.
- **Glucose intolerance or diabetes mellitus.**
- **Poor wound healing:** Due to cortisol's immunosuppressive effects.

3. First-Line Investigations:

The diagnostic process for Cushing's disease includes demonstrating **excess cortisol** and determining the **source** of ACTH overproduction.

a) 24-Hour Urinary Free Cortisol:

- Measures **free cortisol** excreted in the urine over 24 hours.
- **Elevated levels** confirm hypercortisolism.

b) Low-Dose Dexamethasone Suppression Test:

- A **screening test** to confirm the diagnosis of Cushing's syndrome.
- **Dexamethasone** is a synthetic glucocorticoid that suppresses cortisol production by negative feedback in healthy individuals.
 - **Normal response:** Suppression of cortisol to < 50 nmol/L.
 - **Cushing's disease:** Cortisol remains elevated.

c) Late-Night Salivary Cortisol:

- Measures **salivary cortisol** at midnight, when cortisol levels should normally be low.
- Elevated levels indicate **loss of normal diurnal cortisol rhythm**, consistent with Cushing's syndrome.

d) Plasma ACTH:

- **ACTH levels** help differentiate between ACTH-dependent (e.g., pituitary adenoma in Cushing's disease) and ACTH-independent (e.g., adrenal tumour) causes of Cushing's syndrome.
 - **High ACTH:** Suggests **Cushing's disease** or ectopic ACTH secretion.
 - **Low ACTH:** Suggests an adrenal cause.

e) High-Dose Dexamethasone Suppression Test:

- Used to differentiate **Cushing's disease** from **ectopic ACTH secretion**.
 - In **Cushing's disease**, high doses of dexamethasone suppress cortisol production.
 - In **ectopic ACTH secretion**, cortisol remains unsuppressed.

f) MRI of the Pituitary:

- **MRI** is used to identify a **pituitary adenoma**. However, small adenomas may not always be visible, and some cases may require further testing such as **inferior petrosal sinus sampling**.

g) Inferior Petrosal Sinus Sampling (IPSS):

- A specialised test used when MRI findings are inconclusive.
- **ACTH levels** are measured from the veins draining the pituitary gland (petrosal sinuses). If the ACTH levels are significantly higher here than in the peripheral veins, this confirms **pituitary ACTH secretion**.

4. Explanation of Investigations:

- **Low-dose dexamethasone suppression test:** Cushing's disease is confirmed if cortisol is **not suppressed** after low-dose dexamethasone, indicating loss of feedback inhibition.
- **Plasma ACTH:** Elevated ACTH indicates an **ACTH-dependent** cause, pointing towards either Cushing's disease or ectopic ACTH production.
- **High-dose dexamethasone test:** Helps differentiate **Cushing's disease** (partial suppression of cortisol) from ectopic ACTH production (no suppression).
- **MRI pituitary:** Identifies **pituitary adenomas**, though smaller ones may be missed.

5. Diagnosis Criteria for Cushing's Disease:

The diagnosis of **Cushing's disease** is confirmed based on:

1. **Elevated cortisol levels** (via 24-hour urinary free cortisol or failure of suppression in the low-dose dexamethasone test).
2. **ACTH-dependent** Cushing's syndrome (high plasma ACTH levels).
3. **Partial suppression** of cortisol in the **high-dose dexamethasone suppression test**.
4. **MRI evidence** of a pituitary adenoma or confirmation by **inferior petrosal sinus sampling**.

6. First-Line Therapy According to Guidelines:

a) Surgery:

- The first-line treatment for Cushing's disease is **transsphenoidal surgery** to remove the **pituitary adenoma**.
 - Surgery is curative in around 70-80% of patients.
 - **Post-operative remission** is indicated by low morning cortisol levels within a few days after surgery.

b) Radiotherapy:

- **Pituitary radiotherapy** is considered for patients in whom surgery is unsuccessful or not possible.
- Radiotherapy is also used for **residual** or **recurrent tumours**.

c) Medical Therapy:

- If surgery or radiotherapy fails, **medical management** may be necessary to control cortisol levels:
 - **Metyrapone:** Inhibits cortisol synthesis by blocking the enzyme 11 β -hydroxylase.
 - **Ketoconazole:** An antifungal that also inhibits cortisol synthesis.
 - **Pasireotide:** A somatostatin analogue that directly inhibits ACTH release from the pituitary.
 - **Mitotane:** A potent adrenolytic agent used in refractory cases.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Surgery** may be contraindicated in patients with significant comorbidities or those who are unfit for anaesthesia.
- **Radiotherapy** is contraindicated in younger patients due to the risk of hypopituitarism and secondary malignancy.

b) Second-Line Therapy:

- **Metyrapone, ketoconazole, and mitotane** are second-line options when surgery or radiotherapy is not possible or if the patient is awaiting surgery.

8. Routine Monitoring and Follow-Up:

1. Post-Surgical Monitoring:

- **Morning cortisol levels** are measured post-surgery to confirm remission.
- Monitoring for **hypopituitarism** is crucial as pituitary function can be affected by surgery or radiotherapy.

2. Long-Term Monitoring:

- Regular monitoring for **recurrence** of Cushing's disease.
- **ACTH and cortisol** levels are monitored periodically to assess for recurrence.
- **MRI scans** may be needed for follow-up, especially if the adenoma was incompletely resected.

3. Monitoring for Hypopituitarism:

- Patients who undergo surgery or radiotherapy require ongoing monitoring for **pituitary hormone deficiencies** and may need lifelong hormone replacement (e.g., **thyroxine, corticosteroids, growth hormone, sex steroids**).

9. Complications:

a) Cardiovascular Complications:

- **Hypertension, diabetes, and hyperlipidaemia** are common in Cushing's disease, increasing the risk of **stroke, heart attack, and heart failure**.

b) Osteoporosis:

- Chronic cortisol excess leads to **bone demineralisation**, increasing the risk of fractures.

c) Infections:

- Cortisol-induced **immunosuppression** increases the risk of infections.

d) Post-Surgical Hypopituitarism:

- **Pituitary hormone deficiencies** (e.g., **adrenal insufficiency, hypothyroidism, hypogonadism**) may occur after surgery, requiring lifelong hormone replacement.

e) Recurrence:

- **Recurrence of Cushing's disease** occurs in up to 20% of patients after surgery, particularly if the adenoma was not fully resected.

Summary of Key Points for Cushing's Disease:

- **Cushing's disease** is caused by a **pituitary adenoma** that leads to excess **ACTH** secretion and subsequent **cortisol overproduction**.
- Symptoms include **central obesity, moon face, hypertension, muscle weakness, and skin changes**.

139. Pituitary Tumours

1. Detailed Definition of Pituitary Tumours:

Pituitary tumours are **abnormal growths** that develop in the **pituitary gland**, which is located at the base of the brain. They can either be **functioning** (hormone-secreting) or **non-functioning** (non-hormone-secreting). Most pituitary tumours are **benign adenomas**, but they can still have significant clinical effects due to **hormone overproduction**, **hormone deficiency** from gland compression, or **mass effect** on surrounding structures (e.g., optic chiasm).

- **Microadenomas:** Tumours < 1 cm in size.
- **Macroadenomas:** Tumours ≥ 1 cm in size.

Types of functioning tumours include:

- **Prolactinomas** (most common): Secrete **prolactin**.
- **Somatotroph adenomas:** Secrete **growth hormone (GH)**.
- **Corticotroph adenomas:** Secrete **adrenocorticotrophic hormone (ACTH)**, leading to **Cushing's disease**.
- **Thyrotroph adenomas:** Secrete **thyroid-stimulating hormone (TSH)** (rare).
- **Gonadotroph adenomas:** Secrete **luteinising hormone (LH)** and **follicle-stimulating hormone (FSH)** (rare).

2. Common Presenting Complaints and Symptoms:

a) General Symptoms (due to mass effect):

- **Headache:** Often dull and non-specific.
- **Visual field defects:** Typically **bitemporal hemianopia** due to compression of the **optic chiasm**.
- **Hypopituitarism:** Compression of the normal pituitary gland can lead to deficiency of one or more pituitary hormones:
 - **Fatigue, hypotension, weight loss** (due to low cortisol).
 - **Hypothyroidism** symptoms (e.g., cold intolerance, lethargy).
 - **Reduced libido, amenorrhoea** (in women), and **erectile dysfunction** (in men).

b) Functioning Tumours (due to hormone overproduction):

1. **Prolactinomas** (prolactin-secreting adenomas):
 - **Galactorrhoea:** Milky nipple discharge.
 - **Amenorrhoea:** Loss of menstrual periods.
 - **Infertility** in women.
 - **Erectile dysfunction** and **loss of libido** in men.
2. **Somatotroph adenomas** (GH-secreting adenomas):
 - **Acromegaly** in adults: Enlargement of hands, feet, jaw, and coarse facial features.
 - **Gigantism** in children: Excessive linear growth before epiphyseal plate closure.
3. **Corticotroph adenomas** (ACTH-secreting adenomas, **Cushing's disease**):
 - Features of **Cushing's syndrome:** Central obesity, moon face, hypertension, and proximal muscle weakness.
4. **Thyrotroph adenomas** (TSH-secreting adenomas):
 - Symptoms of **hyperthyroidism:** Weight loss, palpitations, tremor, and heat intolerance.

3. First-Line Investigations:

a) Hormone Levels:

- **Prolactin:** Elevated in prolactinomas.
- **Growth hormone (GH)** and **insulin-like growth factor 1 (IGF-1):** Elevated in acromegaly/gigantism.

- **ACTH and cortisol:** Elevated in Cushing's disease.
- **TSH and thyroid hormones (T3, T4):** Elevated in thyrotroph adenomas.
- **LH and FSH:** Can be elevated in gonadotroph adenomas (rare).

b) Visual Field Testing:

- **Perimetry:** To assess for **bitemporal hemianopia**, which is common in macroadenomas due to **optic chiasm compression**.

c) Imaging:

- **MRI of the pituitary:** The imaging modality of choice to visualise the **size** and **location** of the pituitary tumour and assess for compression of surrounding structures.
 - **Microadenomas:** Usually confined to the sella turcica.
 - **Macroadenomas:** May extend into the surrounding areas, compressing the optic chiasm or cavernous sinus.

4. Explanation of Investigations:

- **Prolactin levels:** High levels confirm a **prolactinoma**.
- **Growth hormone/IGF-1 levels:** IGF-1 is used as a more stable marker of GH overproduction in acromegaly/gigantism.
- **ACTH and cortisol:** Elevated levels in the presence of symptoms confirm **Cushing's disease**.
- **Visual field testing:** Detects **bitemporal hemianopia** caused by compression of the optic chiasm.
- **MRI pituitary:** Provides detailed information on the size and location of the adenoma.

5. Diagnosis Criteria for Pituitary Tumours:

- **Confirmed hormone excess** (e.g., elevated prolactin, GH, ACTH, or TSH levels).
- **Imaging evidence** of a pituitary tumour on **MRI**.
- **Visual field defects** (if present) further support the diagnosis, especially in larger tumours.

6. First-Line Therapy According to Guidelines:

a) Prolactinomas:

- **Medical therapy** is first-line for prolactinomas:
 - **Dopamine agonists** (e.g., **cabergoline** or **bromocriptine**): These medications suppress prolactin secretion and often reduce tumour size.
 - **Cabergoline:** Starting dose of 0.25 mg twice weekly, titrated according to response.
 - Surgery is rarely required for prolactinomas unless there is a lack of response to medical therapy or compression of surrounding structures.

b) Somatotroph Adenomas (Acromegaly):

- **Surgery: Transsphenoidal surgery** to remove the pituitary tumour is the first-line treatment.
- **Medical therapy:** If surgery is not curative or feasible, options include:
 - **Somatostatin analogues** (e.g., **octreotide**).
 - **GH receptor antagonists** (e.g., **pegvisomant**).
 - **Dopamine agonists** may also be used in some cases.

c) Corticotroph Adenomas (Cushing's Disease):

- **Surgical resection** of the pituitary adenoma via the **transsphenoidal approach** is the first-line treatment.

- If surgery is unsuccessful, **radiotherapy** or **medical therapy** (e.g., **ketoconazole**, **metyrapone**) may be used to control cortisol levels.

d) Non-Functioning Pituitary Adenomas:

- If the tumour is causing **mass effect** (e.g., visual field defects), **surgical removal** via the **transsphenoidal approach** is indicated.
- For small, non-functioning adenomas that are not causing symptoms, **watchful waiting** with periodic MRI and hormone monitoring may be appropriate.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Surgery** may be contraindicated in patients with significant comorbidities or if the tumour is located near critical brain structures.

b) Second-Line Therapy:

- **Radiotherapy:** May be used as an adjunct in patients with residual tumour or recurrent disease post-surgery.
- **Medical therapy:**
 - For **prolactinomas:** **Dopamine agonists** remain the treatment of choice, but surgery is considered if medication is ineffective.
 - For **acromegaly** and **Cushing's disease**, medical therapy such as **somatostatin analogues** or **GH receptor antagonists** can be used if surgery is unsuccessful.

8. Routine Monitoring and Follow-Up:

1. Hormone Levels:

- Regular monitoring of hormone levels (e.g., **prolactin**, **GH**, **ACTH**) to assess treatment response and screen for recurrence.

2. Imaging:

- **MRI scans** should be performed periodically to monitor the tumour size, particularly for non-functioning adenomas.

3. Visual Field Testing:

- **Perimetry** should be performed regularly in patients with macroadenomas to monitor for improvement or worsening of visual field defects post-treatment.

4. Pituitary Function:

- Assess for **hypopituitarism** in patients undergoing surgery or radiotherapy, as hormone deficiencies may develop over time.

9. Complications:

a) Hypopituitarism:

- Surgery or radiotherapy can result in loss of normal pituitary function, necessitating lifelong hormone replacement (e.g., **corticosteroids**, **thyroid hormone**, **sex hormones**).

b) Visual Loss:

- Untreated or large **macroadenomas** can lead to permanent **vision loss** due to **optic chiasm compression**, causing **bitemporal hemianopia**. Early treatment can prevent this complication.

c) Recurrence:

- **Pituitary tumours**, especially **functioning adenomas**, can recur after treatment. Long-term follow-up with **hormone levels** and **MRI imaging** is required to detect recurrence.

d) Complications from Hormone Excess:

- **Prolonged hormone excess** (e.g., excess cortisol in Cushing's disease, excess GH in acromegaly) can lead to systemic complications like **diabetes mellitus**, **hypertension**, **cardiovascular disease**, and **osteoporosis**.

e) Complications of Treatment:

- **Surgery** may cause **cerebrospinal fluid (CSF) leak** or **meningitis**.
- **Radiotherapy** increases the risk of developing **secondary malignancies** or worsening **hypopituitarism** over time.

Summary of Key Points for Pituitary Tumours:

- **Pituitary tumours** can cause either hormone overproduction or deficiency, or symptoms from **mass effect** (e.g., visual field defects).
- **First-line investigations** include **hormone levels**, **visual field testing**, and **MRI of the pituitary**.
- **Surgical resection** via the **transsphenoidal approach** is the first-line treatment for most functioning and large non-functioning tumours.
- **Medical therapy** (e.g., **dopamine agonists** for prolactinomas) and **radiotherapy** are used in specific cases, particularly when surgery is not curative or feasible.
- **Regular monitoring** of hormone levels, imaging, and pituitary function is crucial for long-term management to detect recurrence and prevent complications.

140. Hyperparathyroidism

1. Detailed Definition of Hyperparathyroidism:

Hyperparathyroidism is a condition characterised by the **excessive production of parathyroid hormone (PTH)** by the **parathyroid glands**, leading to **hypercalcaemia**. PTH is responsible for regulating calcium and phosphate levels in the body, primarily by increasing calcium reabsorption from the bones, kidneys, and gastrointestinal tract. Hyperparathyroidism can be classified into:

1. **Primary Hyperparathyroidism:** Autonomous overproduction of PTH, usually caused by a **parathyroid adenoma**, **hyperplasia**, or, less commonly, a **parathyroid carcinoma**.
2. **Secondary Hyperparathyroidism:** Compensatory overproduction of PTH in response to **hypocalcaemia**, often due to **chronic kidney disease (CKD)** or **vitamin D deficiency**.
3. **Tertiary Hyperparathyroidism:** Occurs after prolonged secondary hyperparathyroidism when the parathyroid glands become **autonomous** and secrete PTH independently of calcium levels.

2. Common Presenting Complaints and Symptoms:

Patients with **primary hyperparathyroidism** often present with features of **hypercalcaemia**:

- **Bones:**
 - Bone pain.
 - Osteoporosis or osteopenia (due to increased bone resorption).
 - Pathological fractures.
- **Stones:**
 - Renal stones (nephrolithiasis) due to elevated calcium levels.
- **Abdominal groans:**
 - Constipation.
 - Nausea, vomiting.
 - Peptic ulcers or pancreatitis (due to hypercalcaemia).
- **Psychiatric overtones:**

- Depression, anxiety, irritability.
- Cognitive dysfunction or confusion.
- **Fatigue** and **muscle weakness**.
- **Polyuria** and **polydipsia** (due to hypercalcaemia-induced nephrogenic diabetes insipidus).

In **secondary hyperparathyroidism**, patients may have symptoms of the **underlying cause**, such as **bone pain** and **renal failure** from chronic kidney disease.

3. First-Line Investigations:

a) Serum Calcium and Phosphate:

- **Serum calcium:** Elevated in primary and tertiary hyperparathyroidism. Normal or low in secondary hyperparathyroidism.
- **Serum phosphate:** Often **low** in primary hyperparathyroidism due to increased renal excretion of phosphate.

b) Parathyroid Hormone (PTH):

- **PTH levels** are elevated in all forms of hyperparathyroidism.
 - In **primary hyperparathyroidism**, both PTH and calcium are elevated.
 - In **secondary hyperparathyroidism**, PTH is elevated in response to low calcium levels.
 - In **tertiary hyperparathyroidism**, PTH remains elevated despite normal or high calcium.

c) Serum 25-hydroxyvitamin D:

- **Vitamin D levels** may be low, particularly in secondary hyperparathyroidism caused by **vitamin D deficiency** or **chronic kidney disease**.

d) Serum Creatinine and Estimated Glomerular Filtration Rate (eGFR):

- To assess for **chronic kidney disease** as a cause of secondary hyperparathyroidism.

e) 24-Hour Urine Calcium:

- May be used to differentiate **familial hypocalciuric hypercalcaemia (FHH)** from **primary hyperparathyroidism**. FHH is associated with low urinary calcium excretion despite high serum calcium levels.

f) Bone Densitometry (DEXA Scan):

- A **DEXA scan** may be performed to assess bone density and check for **osteoporosis** or **osteopenia**, which are common in primary hyperparathyroidism.

g) Imaging (Sestamibi Scan and Ultrasound):

- A **sestamibi scan** is used to localise an overactive parathyroid gland (usually a parathyroid adenoma).
- **Neck ultrasound** may also be used to assess parathyroid gland enlargement.

4. Explanation of Investigations:

- **Serum calcium and PTH levels:** In primary hyperparathyroidism, both PTH and calcium are elevated, whereas in secondary hyperparathyroidism, PTH is elevated in response to low calcium.
- **Sestamibi scan:** Helps to localise parathyroid adenomas, guiding surgical intervention if necessary.
- **24-hour urine calcium:** Differentiates **familial hypocalciuric hypercalcaemia** (low urinary calcium) from **primary hyperparathyroidism** (normal or high urinary calcium).

5. Diagnosis Criteria for Hyperparathyroidism:

The diagnosis of **primary hyperparathyroidism** is confirmed by:

1. **Elevated serum calcium** levels.
2. **Elevated or inappropriately normal PTH** levels (in the context of hypercalcaemia).
3. **Exclusion of other causes of hypercalcaemia** (e.g., malignancy, familial hypocalciuric hypercalcaemia).

In **secondary hyperparathyroidism**, PTH is elevated in response to **hypocalcaemia**, usually secondary to **vitamin D deficiency** or **chronic kidney disease**.

6. First-Line Therapy According to Guidelines:

a) Primary Hyperparathyroidism:

- **Surgical removal (parathyroidectomy)** is the first-line treatment for symptomatic primary hyperparathyroidism, especially in patients with:
 - Symptomatic hypercalcaemia (e.g., renal stones, fractures).
 - Osteoporosis or reduced bone mineral density.
 - Serum calcium greater than 0.25 mmol/L above the upper limit of normal.
 - Age < 50 years.
- For patients who are **asymptomatic** or unfit for surgery:
 - **Hydration**: Encourage increased fluid intake to reduce the risk of kidney stones.
 - **Bisphosphonates** (e.g., alendronate) can be used to reduce bone resorption.
 - **Cinacalcet**: A **calcimimetic** that lowers PTH and calcium levels in patients with primary hyperparathyroidism who are not surgical candidates.
 - Starting dose: **30 mg twice daily**, titrated according to response.

b) Secondary Hyperparathyroidism:

- **Vitamin D supplementation** (e.g., **cholecalciferol** or **ergocalciferol**) for patients with vitamin D deficiency.
- In **chronic kidney disease**, treatment includes:
 - **Phosphate binders** (e.g., **sevelamer**) to reduce phosphate levels.
 - **Active vitamin D analogues** (e.g., **alfacalcidol** or **calcitriol**).
 - **Cinacalcet**: May be used to reduce PTH levels in severe or refractory cases.

c) Tertiary Hyperparathyroidism:

- **Surgical parathyroidectomy** is often required if PTH secretion becomes autonomous after long-standing secondary hyperparathyroidism, particularly in patients with **renal disease**.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Parathyroid surgery** may be contraindicated in elderly or frail patients or those with multiple comorbidities.

b) Second-Line Therapy:

- **Cinacalcet** can be used in patients with **primary hyperparathyroidism** who are not fit for surgery or in those with **secondary/tertiary hyperparathyroidism** who do not respond to standard treatments.

8. Routine Monitoring and Follow-Up:

1. Serum Calcium and PTH Levels:

- Regular monitoring of **calcium** and **PTH levels** in patients who are asymptomatic or not undergoing surgery.

- Monitoring is also required post-surgery to ensure that calcium and PTH levels have normalised.
- 2. **Renal Function:**
 - Monitoring **serum creatinine** and **eGFR** in patients with **secondary hyperparathyroidism** due to chronic kidney disease.
- 3. **Bone Density (DEXA Scan):**
 - Regular DEXA scans to assess for **osteoporosis** or worsening bone density in patients with untreated primary hyperparathyroidism.

9. Complications:

a) Osteoporosis and Fractures:

- Untreated hyperparathyroidism leads to **bone resorption**, increasing the risk of **osteoporosis** and **pathological fractures**.

b) Renal Complications:

- Chronic **hypercalcaemia** can lead to the formation of **renal stones**, **nephrocalcinosis**, and ultimately **renal failure** if untreated.

c) Hypercalcaemic Crisis:

- Rarely, severe hypercalcaemia may lead to **hypercalcaemic crisis**, which presents with **confusion**, **dehydration**, and even **coma**. This is a medical emergency requiring urgent hydration and treatment with **bisphosphonates** or **calcitonin**.

d) Cardiovascular Complications:

- Chronic hyperparathyroidism is associated with increased cardiovascular risks, including **hypertension**, **arrhythmias**, and **vascular calcification**.

141. Hypoparathyroidism

1. Detailed Definition of Hypoparathyroidism:

Hypoparathyroidism is a condition characterised by **inadequate production or action of parathyroid hormone (PTH)**, leading to **hypocalcaemia** (low serum calcium levels). PTH plays a crucial role in maintaining calcium and phosphate balance, and its deficiency results in reduced calcium levels and elevated phosphate levels.

The most common cause of hypoparathyroidism is **surgical removal** or damage to the parathyroid glands during **thyroid or parathyroid surgery**. Other causes include **autoimmune disease**, **genetic disorders**, or **radiation therapy**.

2. Common Presenting Complaints and Symptoms:

Patients with hypoparathyroidism typically present with symptoms related to **hypocalcaemia**:

- **Tetany**: Involuntary muscle contractions, cramps, and spasms, especially in the hands and feet (Trousseau's sign and Chvostek's sign).
- **Perioral and peripheral paraesthesia**: Tingling and numbness around the mouth and in the fingers and toes.
- **Muscle cramps**.
- **Fatigue**.
- **Seizures**: Due to severe hypocalcaemia.
- **Laryngospasm** or **bronchospasm**: In extreme cases.
- **Mood changes**: Irritability, anxiety, or depression.
- **Cataracts** and **dry skin**: In chronic hypocalcaemia.

3. First-Line Investigations:

a) Serum Calcium:

- **Low serum calcium** (< 2.1 mmol/L) is the hallmark of hypoparathyroidism.

b) Serum Parathyroid Hormone (PTH):

- **Low or inappropriately normal PTH** in the context of hypocalcaemia confirms the diagnosis of **hypoparathyroidism**.

c) Serum Phosphate:

- **Elevated phosphate** levels (> 1.5 mmol/L) are commonly seen in hypoparathyroidism due to reduced renal excretion of phosphate.

d) Serum Magnesium:

- Hypomagnesaemia can cause **PTH resistance** or inhibit PTH secretion, leading to **hypocalcaemia**. It is important to assess and correct magnesium levels.

e) ECG:

- May show **prolonged QT interval**, which is a sign of **hypocalcaemia** and can predispose patients to arrhythmias.

4. Explanation of Investigations:

- **Serum calcium and PTH levels:** Low calcium with low or normal PTH confirms the diagnosis of hypoparathyroidism.
- **Serum phosphate:** High phosphate levels help differentiate hypoparathyroidism from other causes of hypocalcaemia.
- **ECG:** Prolonged QT interval is a sign of hypocalcaemia, which may indicate the severity of the condition and the need for urgent correction.

5. Diagnosis Criteria for Hypoparathyroidism:

The diagnosis of **hypoparathyroidism** is confirmed by:

1. **Low serum calcium** levels.
2. **Low or inappropriately normal PTH** levels.
3. **Elevated serum phosphate** levels (in primary hypoparathyroidism).
4. Exclusion of other causes of **hypocalcaemia**, such as **vitamin D deficiency** or **chronic kidney disease**.

6. First-Line Therapy According to Guidelines:

a) Acute Hypocalcaemia (Severe Hypoparathyroidism):

- **Intravenous calcium gluconate** is given for acute, symptomatic hypocalcaemia (e.g., tetany, seizures):
 - Dose: **10 mL of 10% calcium gluconate** (2.25 mmol calcium) administered slowly IV, followed by continuous infusion if necessary.
- **Magnesium replacement** if hypomagnesaemia is present, as it can exacerbate hypocalcaemia.
- **Monitor** serum calcium every 4-6 hours during acute treatment.

b) Chronic Hypoparathyroidism:

- **Oral calcium supplements:**
 - **Calcium carbonate** or **calcium citrate** (1-3 g daily in divided doses) is used to maintain serum calcium levels.
- **Active vitamin D (calcitriol):**
 - Vitamin D is essential to improve calcium absorption from the gut. **Calcitriol** (0.25-1 mcg daily) is the active form of vitamin D used in hypoparathyroidism because it bypasses the kidney's conversion process.

- **Magnesium supplementation:**
 - If magnesium levels are low, oral magnesium supplements should be given to correct any deficiency.

c) Recombinant PTH (Teriparatide or Natpara):

- In patients with **poor control** of calcium levels or **severe** chronic hypoparathyroidism, **recombinant human PTH** (teriparatide) may be used as an adjunct to calcium and vitamin D therapy.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Calcium supplementation** may cause **hypercalcaemia** or **hypercalciuria**, leading to **kidney stones** or **nephrocalcinosis** if not properly monitored.
- **Vitamin D therapy** should be carefully monitored to avoid hypercalcaemia and complications such as renal stones.

b) Second-Line Therapy:

- **Recombinant PTH** (e.g., **Natpara**) may be considered for patients with **chronic hypoparathyroidism** who are not adequately controlled with calcium and vitamin D supplements alone.

8. Routine Monitoring and Follow-Up:

1. Serum Calcium:

- Monitor calcium levels regularly to avoid both **hypocalcaemia** and **hypercalcaemia**. Frequency of monitoring depends on the stability of the patient's condition, but typically monthly during initiation, then every 3-6 months.

2. Serum Phosphate:

- Periodic monitoring is required to ensure phosphate levels are not too high.

3. Renal Function:

- Monitor for **hypercalciuria** and **kidney stones**, especially in patients on long-term calcium and vitamin D therapy.

4. Urinary Calcium:

- 24-hour urinary calcium excretion should be monitored to assess for **hypercalciuria**, which increases the risk of **nephrocalcinosis** and **kidney stones**.

9. Complications:

a) Chronic Hypocalcaemia:

- **Neuromuscular symptoms** such as **tetany**, **seizures**, and **muscle cramps** can become more frequent and severe if untreated.

b) Kidney Stones and Nephrocalcinosis:

- Excessive calcium or vitamin D supplementation can result in **hypercalciuria**, leading to the development of **kidney stones** or **calcification of renal parenchyma**.

c) Cardiovascular Complications:

- **Prolonged QT interval** from hypocalcaemia can predispose to **arrhythmias**. In severe cases, this can be life-threatening.

d) Cataracts:

- Chronic untreated hypocalcaemia can lead to the development of **cataracts**.

Summary of Key Points for Hypoparathyroidism:

- **Hypoparathyroidism** is characterised by **low calcium** and **low PTH** levels, commonly due to **surgical damage** to the parathyroid glands.
- Symptoms include **tetany**, **muscle cramps**, **seizures**, and **paraesthesia** due to hypocalcaemia.
- **First-line treatment** for acute hypocalcaemia is **IV calcium gluconate**, while chronic management includes **oral calcium** and **active vitamin D supplements** (calcitriol).
- **Regular monitoring** of serum calcium, phosphate, and renal function is crucial to avoid complications such as **hypercalciuria**, **kidney stones**, and **nephrocalcinosis**.

142. Hypercalcaemia

1. Detailed Definition of Hypercalcaemia:

Hypercalcaemia refers to an abnormally high level of **calcium in the blood** (typically defined as **serum calcium > 2.6 mmol/L**). It is a relatively common biochemical abnormality that can be caused by various underlying conditions. The most common causes include **primary hyperparathyroidism** and **malignancy**.

2. Common Presenting Complaints and Symptoms:

The symptoms of hypercalcaemia can be remembered using the mnemonic "**Stones, Bones, Groans, Thrones, and Psychiatric Overtones**":

- **Stones:**
 - **Renal stones** (nephrolithiasis), polyuria, and polydipsia due to nephrogenic diabetes insipidus.
- **Bones:**
 - **Bone pain** and **osteopenia** or **osteoporosis** due to increased bone resorption, especially in **primary hyperparathyroidism**.
- **Groans** (gastrointestinal symptoms):
 - **Nausea, vomiting, constipation, abdominal pain, peptic ulcers, and pancreatitis.**
- **Thrones** (urinary symptoms):
 - **Polyuria, dehydration, and frequent urination** due to impaired kidney function.
- **Psychiatric Overtones:**
 - **Confusion, depression, anxiety, fatigue, irritability, memory loss, or even psychosis.**

Other general symptoms include:

- **Muscle weakness.**
- **Hypertension** (in some cases).
- **Cardiac arrhythmias**, particularly with more severe hypercalcaemia.

3. First-Line Investigations:

a) Serum Calcium:

- **Elevated serum calcium** (total calcium > 2.6 mmol/L).

b) Serum Parathyroid Hormone (PTH):

- Helps differentiate between causes of hypercalcaemia.
 - **Elevated PTH** suggests **primary hyperparathyroidism**.
 - **Low or undetectable PTH** suggests a **non-parathyroid cause** such as **malignancy**.

c) Serum Phosphate:

- **Low phosphate** is often seen in **primary hyperparathyroidism** due to increased renal excretion of phosphate.
- **Normal or high phosphate** may indicate other causes like malignancy.

d) Serum Vitamin D:

- **Elevated vitamin D** levels (especially 1,25(OH)₂D) suggest **vitamin D intoxication** or **granulomatous diseases** such as sarcoidosis.

e) ECG:

- May show a **shortened QT interval**, which is a characteristic feature of hypercalcaemia.

f) Further Tests for Malignancy:

- **PTH-related peptide (PTHrP):** Elevated in **humoral hypercalcaemia of malignancy** (common in squamous cell carcinomas).
- **Chest X-ray, CT scans, or bone scans:** If malignancy is suspected, to look for primary or metastatic cancer.

4. Explanation of Investigations:

- **Serum calcium:** Confirms the diagnosis of hypercalcaemia.
- **PTH levels:** Help distinguish between **PTH-mediated causes** (e.g., primary hyperparathyroidism) and **non-PTH-mediated causes** (e.g., malignancy).
- **PTHrP:** Indicative of **malignancy-related hypercalcaemia** (commonly due to lung, breast, or renal cancer).

5. Diagnosis Criteria for Hypercalcaemia:

- **Hypercalcaemia** is diagnosed based on a **serum calcium level > 2.6 mmol/L**.
- The **underlying cause** can be determined based on **PTH levels, PTHrP**, and other investigations (e.g., imaging studies for malignancy).

6. First-Line Therapy According to Guidelines:

The management of hypercalcaemia depends on the **severity** and **underlying cause**:

a) Mild Hypercalcaemia (Calcium 2.6-3.0 mmol/L):

- **Hydration:** Encourage **increased oral fluid intake** to promote urinary calcium excretion and prevent dehydration.
- **Treat the underlying cause** (e.g., adjusting medications, managing primary hyperparathyroidism).

b) Moderate to Severe Hypercalcaemia (Calcium > 3.0 mmol/L):

- **Intravenous (IV) fluids:** 0.9% **normal saline** is given to correct dehydration and enhance calcium excretion through the kidneys. Initial rate: **3-4 litres/24 hours**.
- **IV bisphosphonates:** **Zoledronic acid** or **pamidronate** to inhibit bone resorption and lower calcium levels:
 - **Zoledronic acid:** 4 mg IV over 15 minutes (preferred for malignancy-related hypercalcaemia).
 - **Pamidronate:** 60-90 mg IV over 2-4 hours.
- **Calcitonin:** Can be used in **acute, severe hypercalcaemia** for rapid but temporary reduction in calcium levels (4-8 IU/kg IM or subcutaneously every 12 hours).
- **Steroids:** In cases of **vitamin D toxicity, granulomatous diseases** (e.g., sarcoidosis), or certain cancers, **glucocorticoids** (e.g., **prednisolone**) can help reduce calcium by inhibiting vitamin D production.
- **Dialysis:** Reserved for patients with **severe hypercalcaemia** and **renal failure**.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Bisphosphonates** should be used cautiously in patients with **renal impairment**.
- **Calcitonin** has a **short duration of action** and is typically only used for immediate, short-term relief.

b) Second-Line Therapy:

- **Denosumab**: A **RANKL inhibitor** that reduces bone resorption. It may be used in **bisphosphonate-resistant cases** or in patients with **renal failure**.
 - Dose: 60 mg subcutaneous injection every 6 months (used in malignancy-related hypercalcaemia).
- **Surgical parathyroidectomy**: May be required in patients with **primary hyperparathyroidism**, particularly if they are symptomatic or have complications such as osteoporosis or renal stones.

8. Routine Monitoring and Follow-Up:

1. Serum Calcium:

- Monitor **serum calcium** levels regularly, particularly after treatment with **bisphosphonates** or **calcitonin**.
- Regular monitoring for **recurrence** is required in cases of **malignancy**.

2. Renal Function:

- Monitor **serum creatinine** and **eGFR** in patients receiving bisphosphonates to assess for renal impairment.

3. ECG Monitoring:

- Particularly in severe cases of hypercalcaemia, monitor for **cardiac arrhythmias** and **shortened QT interval**.

9. Complications:

a) Renal Complications:

- **Nephrolithiasis (kidney stones)** and **nephrocalcinosis** due to prolonged hypercalcaemia, especially in **primary hyperparathyroidism**.

b) Bone Complications:

- **Osteoporosis** and **pathological fractures** from excessive bone resorption due to hyperparathyroidism or malignancy.

c) Cardiovascular Complications:

- **Arrhythmias** and **shortened QT interval** due to severe hypercalcaemia.

d) Hypercalcaemic Crisis:

- A medical emergency characterised by severe hypercalcaemia (> 3.5 mmol/L), which can lead to **confusion**, **coma**, and **renal failure**. This requires urgent IV hydration, bisphosphonates, and potentially dialysis.

Summary of Key Points for Hypercalcaemia:

- **Hypercalcaemia** is defined as **serum calcium > 2.6 mmol/L**, with common causes being **primary hyperparathyroidism** and **malignancy**.
- Patients may present with "**Stones, Bones, Groans, Thrones, and Psychiatric Overtones**", reflecting renal, skeletal, gastrointestinal, and neurological symptoms.
- **First-line investigations** include **serum calcium**, **PTH**, **phosphate**, and **ECG** (for a shortened QT interval).

- **IV fluids and bisphosphonates** (e.g., **zoledronic acid**) are the mainstays of treatment for **moderate to severe hypercalcaemia**.
- **Regular monitoring** of calcium, renal function, and cardiac status is crucial to avoid complications like **renal stones**, **osteoporosis**, and **hypercalcaemic crisis**.

143. Hypocalcaemia

1. Detailed Definition of Hypocalcaemia:

Hypocalcaemia refers to abnormally low levels of **calcium in the blood** (typically defined as **serum calcium < 2.1 mmol/L**). Calcium plays a crucial role in **muscle contraction**, **nerve conduction**, and **bone metabolism**, so low levels can lead to neuromuscular and cardiovascular symptoms. Hypocalcaemia can result from **deficient PTH secretion** (hypoparathyroidism), **vitamin D deficiency**, or **kidney dysfunction**.

2. Common Presenting Complaints and Symptoms:

Symptoms of hypocalcaemia often relate to **neuromuscular irritability** and **cardiac dysfunction**:

- **Neuromuscular symptoms:**
 - **Tetany:** Muscle spasms, particularly in the hands and feet (e.g., **Trousseau's sign**) and facial muscles (e.g., **Chvostek's sign**).
 - **Perioral and peripheral paraesthesia:** Tingling or numbness around the mouth and in the fingers.
 - **Muscle cramps.**
 - **Seizures:** In severe cases.
- **Cardiovascular symptoms:**
 - **Arrhythmias:** Particularly **prolonged QT interval**.
 - **Hypotension.**
- **Psychiatric symptoms:**
 - **Anxiety, irritability, depression.**
 - **Confusion and memory problems** in more chronic cases.
- **Other:**
 - **Dry skin, brittle nails, and hair loss.**
 - **Cataracts:** In chronic hypocalcaemia.

3. First-Line Investigations:

a) Serum Calcium:

- **Low total or ionised calcium** (< 2.1 mmol/L or ionised calcium < 1.15 mmol/L).

b) Serum Parathyroid Hormone (PTH):

- Helps differentiate the cause of hypocalcaemia:
 - **Low or normal PTH:** Suggests **hypoparathyroidism**.
 - **High PTH:** Indicates **secondary causes**, such as **vitamin D deficiency** or **chronic kidney disease**.

c) Serum Phosphate:

- **High phosphate** is commonly seen in **hypoparathyroidism** due to reduced renal excretion of phosphate.
- **Low phosphate** may be seen in **vitamin D deficiency**.

d) Serum Magnesium:

- **Low magnesium** can contribute to **hypocalcaemia** by inhibiting PTH release or action.

e) Serum Vitamin D:

- **Low levels** of 25-hydroxyvitamin D indicate **vitamin D deficiency**, which is a common cause of hypocalcaemia.

f) ECG:

- **Prolonged QT interval** is a characteristic feature of hypocalcaemia and can predispose patients to arrhythmias.

4. Explanation of Investigations:

- **Serum calcium:** Confirms the diagnosis of hypocalcaemia.
- **PTH levels:** Help distinguish between **hypoparathyroidism** and **secondary causes** like **vitamin D deficiency** or **chronic kidney disease**.
- **Serum phosphate:** Can be elevated in **hypoparathyroidism** or low in **vitamin D deficiency**.
- **ECG:** The presence of a **prolonged QT interval** is a marker of severe hypocalcaemia and risk of arrhythmias.

5. Diagnosis Criteria for Hypocalcaemia:

- **Serum calcium < 2.1 mmol/L.**
- **Ionised calcium < 1.15 mmol/L.**
- **Elevated or low PTH**, depending on the underlying cause (e.g., **low PTH** in **hypoparathyroidism** or **elevated PTH** in **secondary hypocalcaemia**).
- **Serum phosphate and magnesium levels** are used to differentiate between different causes of hypocalcaemia.

6. First-Line Therapy According to Guidelines:

The management of hypocalcaemia depends on the **severity** and **underlying cause**:

a) Acute Symptomatic Hypocalcaemia (e.g., tetany, seizures, prolonged QT):

- **Intravenous (IV) calcium gluconate:**
 - **10 mL of 10% calcium gluconate** (2.25 mmol calcium) administered IV over 10-20 minutes, followed by continuous infusion if necessary.
- **Magnesium replacement:**
 - If hypomagnesaemia is present, magnesium should be replaced as it may impair PTH release or action. Magnesium sulfate is commonly used.
- **Monitoring:** Frequent serum calcium measurements every 4-6 hours during treatment.

b) Chronic Hypocalcaemia:

- **Oral calcium supplements:**
 - **Calcium carbonate** or **calcium citrate** (1-3 g daily in divided doses) to maintain normal calcium levels.
- **Vitamin D supplementation:**
 - If hypocalcaemia is due to **vitamin D deficiency**, **cholecalciferol** or **ergocalciferol** is used to replenish vitamin D stores.
 - In patients with **hypoparathyroidism**, **calcitriol** (0.25-1 mcg daily) or **alfacalcidol** (1 mcg daily) is preferred, as these are active forms of vitamin D.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **IV calcium** should be given cautiously in patients with **cardiac arrhythmias** or **renal insufficiency**.

b) Second-Line Therapy:

- **Recombinant PTH** (teriparatide) may be considered in patients with **hypoparathyroidism** who are not controlled on calcium and vitamin D supplementation.

8. Routine Monitoring and Follow-Up:

1. **Serum Calcium:**
 - Monitor **serum calcium** levels regularly, especially in patients on **chronic calcium** and **vitamin D supplementation**.
2. **Serum Magnesium:**
 - Monitor **serum magnesium** levels in patients with persistent hypocalcaemia to ensure hypomagnesaemia is not contributing to the condition.
3. **Renal Function:**
 - Monitor for **hypercalciuria** in patients on long-term **calcium supplementation**, as it may increase the risk of **kidney stones**.

9. Complications:

a) Neuromuscular Symptoms:

- Untreated or poorly managed hypocalcaemia can lead to persistent **tetany**, **muscle spasms**, and even **seizures**.

b) Cardiovascular Complications:

- **Prolonged QT interval** on ECG, increasing the risk of **arrhythmias**.

c) Cataracts:

- Chronic hypocalcaemia, particularly in **hypoparathyroidism**, can lead to the development of **cataracts**.

d) Bone Complications:

- Prolonged hypocalcaemia may lead to **osteomalacia** (softening of the bones) due to defective bone mineralisation, particularly in cases related to **vitamin D deficiency**.

Summary of Key Points for Hypocalcaemia:

- **Hypocalcaemia** is defined as **serum calcium < 2.1 mmol/L**, with causes including **hypoparathyroidism**, **vitamin D deficiency**, and **chronic kidney disease**.
- Common symptoms include **tetany**, **muscle cramps**, **seizures**, and **prolonged QT interval** on ECG.
- **First-line investigations** include **serum calcium**, **PTH**, **phosphate**, and **vitamin D levels**.
- Treatment includes **IV calcium gluconate** for acute cases and **oral calcium and vitamin D supplements** for chronic cases.
- **Regular monitoring** of calcium, magnesium, and renal function is essential to prevent complications such as **arrhythmias**, **kidney stones**, and **cataracts**.

144. SIADH (Syndrome of Inappropriate Antidiuretic Hormone Secretion)

1. Detailed Definition of SIADH:

Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) is a condition characterised by the excessive, inappropriate release of **antidiuretic hormone (ADH)**, which leads to **hyponatraemia** (low sodium levels) and **water retention**. This results in **dilutional**

hyponatraemia where the excess water causes low sodium concentrations in the blood, despite normal or increased total body sodium.

SIADH is associated with a variety of underlying causes, including **malignancies**, **pulmonary disorders**, **central nervous system diseases**, and **certain medications**.

2. Common Presenting Complaints and Symptoms:

Patients with SIADH typically present with symptoms related to **hyponatraemia**, which can vary depending on the severity and rapidity of onset:

Mild Hyponatraemia:

- **Fatigue.**
- **Headache.**
- **Nausea and vomiting.**

Moderate to Severe Hyponatraemia:

- **Confusion or altered mental status.**
- **Muscle cramps and weakness.**
- **Seizures.**
- **Coma** (in severe or rapidly developing cases).

Symptoms Related to the Underlying Cause:

- **Cough or haemoptysis** if caused by lung cancer.
- **Symptoms of CNS pathology**, such as headaches or seizures, if related to a brain injury or tumour.

3. First-Line Investigations:

The diagnosis of SIADH is primarily clinical, supported by laboratory investigations that demonstrate **hyponatraemia** and **low plasma osmolality** with **inappropriately high urine osmolality**:

a) Serum Sodium:

- **Hyponatraemia** (typically < 135 mmol/L) and can be significantly lower in severe cases.

b) Serum Osmolality:

- **Low serum osmolality** (typically < 275 mOsm/kg), which confirms the **dilutional nature** of the hyponatraemia.

c) Urine Osmolality:

- **Inappropriately high urine osmolality** (typically > 100 mOsm/kg), indicating **concentrated urine** despite low serum sodium levels.

d) Urine Sodium:

- **Urine sodium > 30 mmol/L** in the setting of normal renal function and euvolaemia (absence of dehydration or fluid overload).

e) Serum Urea and Creatinine:

- **Normal renal function** helps exclude kidney disease as a cause of hyponatraemia.

f) Serum Cortisol and Thyroid Function Tests:

- These are performed to rule out **adrenal insufficiency** and **hypothyroidism**, which can also cause hyponatraemia.

g) Imaging (CXR, CT, or MRI):

- **Chest X-ray** to check for lung pathology such as **small cell lung cancer** (a common cause of SIADH).
- **CT or MRI brain** to assess for CNS causes, such as **stroke** or **tumours**.

4. Explanation of Investigations:

- **Serum sodium:** Hyponatraemia confirms the diagnosis, and its severity guides management.
- **Serum and urine osmolality:** SIADH is characterised by **dilutional hyponatraemia** (low serum osmolality) with **inappropriately concentrated urine** (high urine osmolality).
- **Urine sodium:** In SIADH, the kidneys excrete sodium inappropriately, leading to elevated urine sodium.
- **Imaging:** Helps to identify potential causes, such as **lung tumours** or **CNS lesions**.

5. Diagnosis Criteria for SIADH:

The diagnosis of SIADH is based on **Bartter and Schwartz's criteria**, which include:

1. **Hyponatraemia** with **low plasma osmolality** (< 275 mOsm/kg).
2. **Inappropriately concentrated urine** (urine osmolality > 100 mOsm/kg).
3. **Euvolaemia** (no signs of dehydration, oedema, or fluid overload).
4. **Elevated urine sodium** (> 30 mmol/L).
5. **Normal thyroid, adrenal, and renal function**.
6. **Absence of diuretic use**.

6. First-Line Therapy According to Guidelines:

The management of SIADH involves correcting the **underlying cause** and treating the **hyponatraemia**. Treatment depends on the **severity** and **symptoms** associated with the hyponatraemia:

a) Mild to Moderate Hyponatraemia (Asymptomatic or Mild Symptoms):

- **Fluid restriction:**
 - The first-line treatment for most cases of SIADH. **Restrict fluid intake to 500-1000 mL/day** to induce negative water balance and correct the hyponatraemia.
- **Dietary salt supplementation:**
 - May be advised alongside fluid restriction to increase serum sodium levels.
- **Monitor serum sodium levels** regularly, with gradual correction to avoid the risk of **osmotic demyelination syndrome**.

b) Severe or Symptomatic Hyponatraemia (e.g., confusion, seizures, coma):

- **Hypertonic saline (3% NaCl):**
 - For patients with **severe hyponatraemia** (< 120 mmol/L) or **symptoms of cerebral oedema** (e.g., seizures or confusion), **3% saline** is used to raise serum sodium slowly (typically **4-6 mmol/L within the first 24 hours**).
- **Medications:**
 - **Vasopressin receptor antagonists (vaptans)** such as **tolvaptan** may be used in patients with **chronic SIADH** where fluid restriction fails.
 - **Demeclocycline:** An older medication that inhibits ADH action in the kidney, though it is rarely used due to potential nephrotoxicity.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Rapid correction of hyponatraemia** should be avoided as it increases the risk of **osmotic demyelination syndrome**, a serious neurological condition.

b) Second-Line Therapy:

- **Tolvaptan** (a vasopressin receptor antagonist) may be used when **fluid restriction** is ineffective or poorly tolerated:

- **Tolvaptan dose:** 15-30 mg daily, though it requires careful monitoring of serum sodium levels.
- **Demeclocycline:** Can be used in cases where **fluid restriction** and **vaptans** are ineffective, though it can cause nephrotoxicity and is less commonly used today.

8. Routine Monitoring and Follow-Up:

1. **Serum Sodium:**
 - Monitor **serum sodium** regularly, especially when initiating treatment. The goal is to raise sodium **gradually** (not more than **8-10 mmol/L per 24 hours**).
2. **Fluid Balance:**
 - Daily monitoring of **fluid input and output** to assess compliance with **fluid restriction** and the effectiveness of therapy.
3. **Urine Output and Osmolality:**
 - Regularly check **urine output** and **urine osmolality** to ensure treatment effectiveness and assess the response to fluid restriction or medication.
4. **Serum Urea and Creatinine:**
 - Monitor **renal function** during treatment, especially if **demeclocycline** is used, as it may impair kidney function.

9. Complications:

a) Osmotic Demyelination Syndrome (Central Pontine Myelinolysis):

- This is the most feared complication of **over-rapid correction of hyponatraemia**. Symptoms include **dysarthria, dysphagia, paralysis**, and **coma**. Prevention involves **gradual correction** of sodium levels.

b) Seizures and Coma:

- Severe hyponatraemia may cause **cerebral oedema**, leading to **seizures, coma**, or **respiratory arrest**.

c) Chronic Hyponatraemia:

- Persistent hyponatraemia can lead to **fatigue, cognitive dysfunction**, and **increased fall risk** in elderly patients.

Summary of Key Points for SIADH:

- **SIADH** is characterised by **hyponatraemia** due to inappropriate secretion of **antidiuretic hormone (ADH)**, leading to water retention and dilutional hyponatraemia.
- Symptoms range from mild (headaches, fatigue) to severe (seizures, coma), depending on the **degree of hyponatraemia**.
- **First-line treatment** is **fluid restriction**, with more severe cases requiring **hypertonic saline** or **vasopressin receptor antagonists** (e.g., tolvaptan).
- **Slow correction** of sodium is essential to avoid complications such as **osmotic demyelination syndrome**. Regular monitoring of serum sodium, urine osmolality, and fluid balance is crucial to managing SIADH effectively.

145. Malignant Hyperpyrexia

1. Detailed Definition of Malignant Hyperpyrexia:

Malignant hyperpyrexia, also known as **malignant hyperthermia**, is a rare but life-threatening **pharmacogenetic disorder** of skeletal muscle, triggered by certain **anaesthetic agents** or **muscle relaxants**. It causes a rapid increase in body temperature and severe muscle contractions when affected individuals are exposed to these drugs. The disorder is caused by an

abnormality in the ryanodine receptor (RYR1) gene, which leads to excessive calcium release from the sarcoplasmic reticulum of muscle cells, causing a hypermetabolic state.

2. Common Presenting Complaints and Symptoms:

The symptoms of malignant hyperpyrexia typically occur after exposure to **triggering agents** (e.g., **volatile anaesthetics** such as **halothane**, **isoflurane**, or **muscle relaxants** like **succinylcholine**):

- **Hyperthermia:**
 - A rapid and extreme rise in body temperature (pyrexia) to **> 40°C (104°F)**.
- **Muscle rigidity:**
 - Particularly affecting the **masseter muscle** and **generalised muscle stiffness**.
- **Tachycardia:**
 - Elevated heart rate due to the hypermetabolic state.
- **Tachypnoea:**
 - Increased respiratory rate as the body tries to compensate for the hypermetabolism.
- **Acidosis:**
 - **Metabolic acidosis** due to increased production of lactate, and **respiratory acidosis** from decreased CO₂ clearance.
- **Rhabdomyolysis:**
 - **Muscle breakdown** leading to **myoglobinuria** (tea-coloured urine) and potential **acute kidney injury (AKI)**.
- **Hyperkalaemia:**
 - Elevated potassium levels due to muscle cell destruction, which may lead to **arrhythmias**.
- **Arrhythmias:**
 - Potential life-threatening heart rhythm disturbances due to **electrolyte imbalances**.
- **Hypotension and shock:**
 - Occur because of the body's inability to compensate for the hypermetabolic state.

3. First-Line Investigations:

The diagnosis of malignant hyperpyrexia is **clinical** but is supported by laboratory findings that confirm the **hypermetabolic state**:

a) Serum Electrolytes:

- **Hyperkalaemia:** Due to muscle breakdown and release of intracellular potassium.

b) Creatine Kinase (CK):

- **Significantly elevated CK** levels (> 10,000 U/L) indicating **rhabdomyolysis**.

c) Blood Gas Analysis:

- **Metabolic acidosis** (low pH, low bicarbonate) with or without **respiratory acidosis** (elevated CO₂ levels).

d) Serum Myoglobin:

- **Increased myoglobin** from muscle breakdown, which may also be seen in the **urine** (myoglobinuria).

e) Coagulation Profile:

- **Coagulopathy** may develop in severe cases, potentially leading to **disseminated intravascular coagulation (DIC)**.

f) Genetic Testing:

- **RYR1 gene testing:** Can confirm susceptibility to malignant hyperpyrexia, though it is not typically used in acute diagnosis.

4. Explanation of Investigations:

- **Serum electrolytes:** Elevated potassium is a sign of muscle breakdown and intracellular potassium release.
- **CK levels:** Very high CK levels indicate severe muscle damage (**rhabdomyolysis**).
- **Blood gas analysis:** Confirms the presence of **acidosis** (metabolic or respiratory), which reflects the hypermetabolic state.
- **Serum myoglobin:** Indicates muscle damage, and **myoglobinuria** may cause acute kidney injury.
- **Genetic testing:** Identifies mutations in the **RYR1 gene**, which predispose to malignant hyperpyrexia.

5. Diagnosis Criteria for Malignant Hyperpyrexia:

The diagnosis of malignant hyperpyrexia is made clinically, based on the following key features:

1. **Exposure to triggering agents** (e.g., halothane, isoflurane, or succinylcholine).
2. **Rapid onset of hyperthermia** (temperature > 40°C) and **muscle rigidity**.
3. **Metabolic and/or respiratory acidosis**.
4. **Elevated CK** and evidence of **rhabdomyolysis**.
5. **Tachycardia, arrhythmias, and hyperkalaemia**.
6. **Family history** of malignant hyperpyrexia or related disorders.

6. First-Line Therapy According to Guidelines:

a) Immediate Management:

- **Stop the triggering agent** immediately (e.g., volatile anaesthetic or succinylcholine) and **discontinue surgery** if possible.
- **Administer intravenous dantrolene**, which is the definitive treatment for malignant hyperpyrexia:
 - Initial dose: **2.5 mg/kg IV**, repeated every 5 minutes until symptoms resolve (up to a maximum of 10 mg/kg).
 - **Dantrolene** works by inhibiting calcium release from the sarcoplasmic reticulum in muscle cells, reducing muscle contractions and heat production.
- **Cool the patient:** Active cooling methods (e.g., **ice packs, cooling blankets, cold IV fluids**) should be initiated to reduce core body temperature.

b) Supportive Therapy:

- **IV fluids:** Aggressive IV hydration with isotonic saline to maintain renal perfusion and prevent **acute kidney injury** from rhabdomyolysis.
- **Manage hyperkalaemia:**
 - Administer **calcium gluconate** to stabilise cardiac membranes.
 - **Insulin and dextrose** to drive potassium into cells, and **salbutamol** or **bicarbonate** as needed.
- **Monitor for arrhythmias:** ECG monitoring is essential, and **anti-arrhythmic drugs** should be given as needed.
- **Correct acidosis:** Administer **sodium bicarbonate** to treat severe metabolic acidosis.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Succinylcholine** and **volatile anaesthetics** should be avoided in patients with a known susceptibility to malignant hyperpyrexia.

b) Second-Line Therapy:

- If **dantrolene** is unavailable, symptomatic treatment of hyperthermia and muscle rigidity should be prioritised. **Cooling methods**, fluid resuscitation, and management of hyperkalaemia are crucial.
- **Post-crisis management:** After stabilisation, patients may require **ICU care** for ongoing monitoring of **renal function**, **electrolytes**, and **cardiac status**.

8. Routine Monitoring and Follow-Up:

1. **Serum Electrolytes:**
 - Monitor **potassium** and **calcium** levels closely during treatment, as electrolyte disturbances are common.
2. **Renal Function:**
 - Monitor **serum creatinine** and **urine output** to assess for **acute kidney injury** secondary to rhabdomyolysis.
3. **ECG Monitoring:**
 - Continuous **cardiac monitoring** to detect arrhythmias associated with **hyperkalaemia** or other metabolic disturbances.
4. **Temperature:**
 - Regularly monitor **core temperature** to assess the effectiveness of cooling measures and prevent hyperthermia recurrence.
5. **Genetic Testing:**
 - Consider **genetic testing** (RYR1 mutation) for the patient and family members after stabilisation to assess for malignant hyperpyrexia susceptibility.

9. Complications:

a) Acute Complications:

- **Cardiac arrhythmias:** Life-threatening arrhythmias due to **hyperkalaemia** and **acidosis**.
- **Acute kidney injury (AKI):** Due to **rhabdomyolysis** and **myoglobinuria**.
- **Disseminated Intravascular Coagulation (DIC):** Can occur due to extensive muscle breakdown and systemic inflammation.
- **Respiratory failure:** Severe acidosis and muscle rigidity can lead to compromised respiratory function.

b) Long-Term Complications:

- **Chronic renal impairment:** From prolonged or untreated rhabdomyolysis.
- **Neurological damage:** May occur due to severe hyperthermia or prolonged acidosis.
- **Recurrent episodes:** Without avoidance of trigger agents, patients are at risk of future episodes of malignant hyperpyrexia.

Summary of Key Points for Malignant Hyperpyrexia:

- **Malignant hyperpyrexia** is a life-threatening condition triggered by **volatile anaesthetics** or **succinylcholine**, leading to **hyperthermia**, **muscle rigidity**, and **metabolic acidosis**.
- Early signs include **rapid temperature rise**, **tachycardia**, **hyperkalaemia**, and **rhabdomyolysis**.

- The first-line treatment is **immediate discontinuation** of the triggering agent and administration of **IV dantrolene**.

146. Poisoning and Overdose

1. Detailed Definition of Poisoning and Overdose:

Poisoning refers to the ingestion, inhalation, or exposure to harmful substances that can cause adverse physiological effects. An **overdose** occurs when a person consumes a substance, typically a drug, in quantities greater than the recommended or safe dose, leading to toxic effects. Overdose may be accidental or intentional, and the substances involved can range from medications (e.g., paracetamol, opioids) to household chemicals or illicit drugs.

2. Common Presenting Complaints and Symptoms:

The symptoms of poisoning or overdose depend on the **substance involved**. Below are the general symptoms and specific signs related to common toxic agents:

General Symptoms:

- **Altered consciousness:** Confusion, drowsiness, or coma.
- **Respiratory depression:** Shallow or slow breathing.
- **Cardiovascular instability:** Tachycardia, bradycardia, hypotension, arrhythmias.
- **Gastrointestinal symptoms:** Nausea, vomiting, abdominal pain.
- **Seizures:** Particularly with **tricyclic antidepressant** or **theophylline overdose**.

Common Toxic Agents and Their Signs:

- **Paracetamol:**
 - Initially, patients may be asymptomatic or have mild nausea/vomiting.
 - **Hepatotoxicity** (liver damage) develops over 24-48 hours, presenting with **right upper quadrant pain, jaundice, and coagulopathy**.
- **Opioids (e.g., heroin, morphine):**
 - **Respiratory depression, pinpoint pupils, and reduced level of consciousness**.
- **Salicylates (e.g., aspirin):**
 - **Tinnitus, metabolic acidosis, respiratory alkalosis, hyperventilation, and nausea/vomiting**.
- **Benzodiazepines:**
 - **Drowsiness, confusion, hypotension, and respiratory depression** in severe cases.
- **Tricyclic Antidepressants (TCA):**
 - **Tachycardia, seizures, arrhythmias, anticholinergic effects** (e.g., dry mouth, urinary retention), and **prolonged QRS interval** on ECG.

3. First-Line Investigations:

a) Blood Tests:

- **Arterial blood gas (ABG):** To assess for **acidosis, alkalosis, and oxygenation**.
- **Serum electrolytes:** Check for **potassium** abnormalities (e.g., hyperkalaemia in digoxin toxicity).
- **Glucose:** To rule out **hypoglycaemia** as a cause of altered mental status.
- **Liver function tests (LFTs):** Important in suspected **paracetamol overdose**.
- **Renal function tests:** Elevated creatinine and urea may indicate **renal damage** due to toxins.

b) Toxicology Screens:

- **Plasma paracetamol levels:** Essential for patients presenting within 24 hours of overdose.
- **Salicylate levels:** If aspirin ingestion is suspected.
- **Urine toxicology:** To screen for **opioids, benzodiazepines, amphetamines**, and other substances.

c) Electrocardiogram (ECG):

- Used to identify arrhythmias or characteristic changes:
 - **Prolonged QT interval** (e.g., in tricyclic antidepressant overdose).
 - **Bradycardia** or **heart block** in **beta-blocker overdose**.

4. Explanation of Investigations:

- **Serum paracetamol levels:** Important for assessing the risk of **hepatic damage** and guiding the administration of **N-acetylcysteine (NAC)**.
- **Blood gas analysis:** Identifies metabolic acidosis, common in **salicylate toxicity** or **ethylene glycol poisoning**.
- **ECG:** Critical for detecting **arrhythmias** in tricyclic antidepressant or beta-blocker overdose.

5. Diagnosis Criteria for Poisoning and Overdose:

- The diagnosis is based on **history of ingestion, clinical presentation, and toxicology results**. In some cases, the diagnosis may be inferred from characteristic signs (e.g., **pinpoint pupils** in opioid overdose) or lab results (e.g., elevated **paracetamol levels**).

6. First-Line Therapy According to Guidelines:

a) General Management:

- **Supportive care:**
 - **Airway, Breathing, and Circulation (ABC):** Ensure a patent airway, adequate breathing, and circulation.
 - **Intravenous fluids:** To correct hypotension and dehydration.
- **Activated charcoal:**
 - Used within **1 hour of ingestion** to reduce absorption of most poisons. Dose: **50 g orally** for adults.

b) Specific Antidotes:

- **Paracetamol overdose:**
 - **N-acetylcysteine (NAC):** Administered if paracetamol levels are above the treatment threshold on the **Rumack-Matthew nomogram**.
 - Dose: **150 mg/kg IV** over 1 hour, followed by 50 mg/kg over 4 hours, and 100 mg/kg over 16 hours.
- **Opioid overdose:**
 - **Naloxone:** 0.4-2 mg IV, repeated as needed to reverse **respiratory depression** and **unconsciousness**.
- **Benzodiazepine overdose:**
 - **Flumazenil:** 200 mcg IV over 15 seconds, repeated as necessary, but used with caution due to the risk of precipitating **seizures**.
- **Tricyclic Antidepressant overdose:**
 - **Sodium bicarbonate:** Given to correct metabolic acidosis and **prolonged QRS interval**.
 - Dose: 50 mmol IV bolus.

- **Beta-blocker overdose:**
 - **Glucagon:** Increases heart rate and contractility in patients with beta-blocker toxicity.
 - Dose: 5 mg IV bolus.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Flumazenil** should not be used in patients with a history of **seizure disorders** or in mixed overdose cases involving **tricyclic antidepressants**, due to the risk of **seizures**.

b) Second-Line Therapy:

- **Haemodialysis** may be used in cases of **salicylate poisoning**, **ethylene glycol poisoning**, or **methanol poisoning** to enhance toxin elimination.
- **Lipid emulsion therapy:** Used in **local anaesthetic toxicity** or severe overdoses of lipid-soluble drugs (e.g., **verapamil** or **propranolol**).

8. Routine Monitoring and Follow-Up:

1. Serum Electrolytes:

- Regularly monitor electrolytes, particularly potassium, sodium, and bicarbonate levels during treatment.

2. Liver Function Tests:

- Monitor LFTs in **paracetamol overdose** to assess for **liver damage**.

3. ECG Monitoring:

- Continuous cardiac monitoring is crucial in cases of **tricyclic antidepressant overdose**, **beta-blocker overdose**, or **cardiotoxic substances**.

4. Renal Function:

- Monitor **renal function** in cases of **rhabdomyolysis** (due to myoglobin release) or **nephrotoxic poisons**.

9. Complications:

a) Renal Failure:

- Can occur due to **rhabdomyolysis** (as seen in **severe overdose**) or **toxic damage** (as in **ethylene glycol poisoning**).

b) Hepatotoxicity:

- Seen in **paracetamol overdose**, with the risk of **acute liver failure** if untreated.

c) Seizures and Arrhythmias:

- Common in **tricyclic antidepressant overdose**, and severe toxicity can lead to **ventricular arrhythmias**.

d) Respiratory Failure:

- Particularly in **opioid** or **benzodiazepine overdose**, due to **respiratory depression**.

Summary of Key Points for Poisoning and Overdose:

- **Poisoning** and **overdose** can result from the ingestion of medications, illicit substances, or toxins. Symptoms vary depending on the substance but typically involve **altered consciousness**, **respiratory depression**, and **cardiovascular instability**.
- **First-line investigations** include **blood gases**, **serum toxicology**, **electrolytes**, and **ECG**.

- Treatment involves **supportive care, activated charcoal** (if early), and specific **antidotes** (e.g., **N-acetylcysteine for paracetamol overdose, naloxone for opioid overdose**).
- **Regular monitoring** of electrolytes, liver function, and cardiac status is essential to manage complications like **hepatic failure, arrhythmias, and renal damage**.

147. Polycystic Ovarian Syndrome (PCOS) and Hirsutism

1. Detailed Definition of Polycystic Ovarian Syndrome (PCOS):

PCOS is a common endocrine disorder affecting women of reproductive age, characterised by **ovarian dysfunction, hyperandrogenism** (elevated male hormones), and **polycystic ovaries** on ultrasound. It is associated with **menstrual irregularities, infertility, and metabolic abnormalities** such as **insulin resistance**.

The **Rotterdam criteria** are widely used to diagnose PCOS. A diagnosis of PCOS requires **two of the following three features**:

Oligo-ovulation or anovulation (irregular or absent periods).

Clinical or biochemical signs of hyperandrogenism (e.g., hirsutism, acne).

Polycystic ovaries on ultrasound (≥ 12 follicles in one ovary or increased ovarian volume >10 mL).

2. Common Presenting Complaints and Symptoms:

PCOS Symptoms:

Irregular menstrual periods: Oligomenorrhoea (infrequent periods) or amenorrhoea (absence of periods).

Infertility: Due to lack of ovulation (anovulation).

Weight gain: Particularly central obesity.

Hyperandrogenism: Manifested as **hirsutism, acne, and alopecia** (male-pattern hair loss).

Insulin resistance: Leading to **acanthosis nigricans** (darkened, velvety skin in body folds).

Hirsutism Symptoms:

Excessive hair growth in areas where males typically grow hair (e.g., face, chest, back).

Thick, dark terminal hairs appear on the upper lip, chin, and sideburns.

3. First-Line Investigations:

a) Blood Tests:

Testosterone: Elevated total or free testosterone is a hallmark of PCOS-related hyperandrogenism.

Sex hormone-binding globulin (SHBG): Often low in PCOS due to hyperinsulinaemia.

Luteinising hormone (LH) and Follicle-stimulating hormone (FSH): A raised **LH ratio** (usually >2:1) is common in PCOS.

Prolactin: To rule out hyperprolactinaemia as a cause of menstrual irregularities.

Thyroid function tests: To rule out thyroid disorders.

Fasting glucose and insulin: To check for **insulin resistance** and **diabetes**.

Lipid profile: To assess for **dyslipidaemia**, which is common in PCOS.

b) Pelvic Ultrasound:

Transvaginal or transabdominal ultrasound is performed to check for **polycystic ovaries**. Diagnosis is based on finding ≥ 12 follicles in one ovary or increased ovarian volume > 10 mL.

c) Hirsutism-Specific Investigations:

Ferriman-Gallwey score: A clinical scoring system used to assess the severity of hirsutism by evaluating hair growth in androgen-sensitive areas.

4. Explanation of Investigations:

Testosterone levels: Elevated testosterone levels reflect **hyperandrogenism**, a key feature of PCOS. Increased androgens lead to **hirsutism**, **acne**, and sometimes **androgenic alopecia**.

Pelvic ultrasound: Helps to visualise **polycystic ovaries**, although not all women with PCOS will have this feature.

5. Diagnosis Criteria for PCOS:

The **Rotterdam criteria** are the most widely accepted diagnostic tool for PCOS. To make a diagnosis, two of the following three features are required:

Oligo-ovulation or anovulation.

Clinical or biochemical hyperandrogenism.

Polycystic ovaries on ultrasound.

It is essential to rule out other causes of hyperandrogenism, such as **congenital adrenal hyperplasia**, **Cushing's syndrome**, and **androgen-secreting tumours**.

6. First-Line Therapy According to Guidelines:

Management of PCOS focuses on addressing the patient's **presenting symptoms**, such as menstrual irregularities, hirsutism, infertility, and metabolic issues.

a) Lifestyle Modifications:

Weight loss: A cornerstone of PCOS management, particularly for overweight or obese patients. Even modest weight loss (5-10%) can help restore ovulation and improve insulin sensitivity.

Dietary modifications: A low **glycaemic index (GI)** diet helps improve **insulin resistance** and reduces the risk of type 2 diabetes.

b) Pharmacological Treatment:

Menstrual Irregularities and Endometrial Protection:

Combined oral contraceptive pill (COCP): First-line treatment to regulate menstrual cycles, provide endometrial protection, and reduce **androgen** production, improving symptoms like **hirsutism** and **acne**.

Hirsutism:

COCPs: Also reduce androgen levels and help manage **excess hair growth**.

Anti-androgens:

Spironolactone (50-100 mg twice daily): An anti-androgen that blocks androgen receptors and reduces hair growth. Used in combination with COCPs to prevent teratogenic effects.

Cyproterone acetate: Also reduces androgen levels but carries a higher risk of side effects and should be used cautiously.

Insulin Resistance and Metabolic Complications:

Metformin: Improves **insulin sensitivity**, helps with weight loss, and may restore **ovulation**. Commonly used in overweight or obese women with PCOS.

Infertility:

Clomifene citrate: First-line for ovulation induction in women with PCOS-related infertility.

Letrozole: An alternative ovulation induction agent that is increasingly used for **fertility treatment** in PCOS.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

COCPs: Contraindicated in women with a history of **venous thromboembolism (VTE)**, **migraine with aura**, **uncontrolled hypertension**, and **smokers** over the age of 35.

Spironolactone: Should be used cautiously in patients with **renal impairment** or **hyperkalaemia**.

b) Second-Line Therapy:

Eflornithine cream: A topical treatment for **hirsutism** that slows the rate of hair growth.

Laser hair removal: Considered for **persistent hirsutism** that is not well controlled with pharmacological treatment.

In vitro fertilisation (IVF): May be necessary for women with **PCOS** who do not respond to ovulation induction treatments for infertility.

8. Routine Monitoring and Follow-Up:

Menstrual Cycle:

Regular monitoring to ensure that **ovulation** and menstrual cycles are improving with treatment.

Weight and BMI:

Regular tracking of weight loss and **BMI** to monitor progress, particularly in patients with **insulin resistance**.

Blood Pressure:

Monitor for hypertension, especially in women on **COCs**.

Blood Glucose and Lipid Profile:

Annual monitoring of **fasting glucose** or **HbA1c** and **lipids** in women with PCOS, as they are at increased risk of **type 2 diabetes** and **cardiovascular disease**.

Potassium Levels:

For women taking **spironolactone**, regular monitoring of **serum potassium** levels is required to avoid **hyperkalaemia**.

9. Complications of PCOS:

Infertility: Due to anovulation, but fertility treatment is often successful.

Type 2 diabetes: PCOS is associated with **insulin resistance**, increasing the risk of developing **type 2 diabetes**.

Endometrial hyperplasia and cancer: Due to prolonged periods of **anovulation** and **unopposed oestrogen** exposure.

Dyslipidaemia: Women with PCOS often have elevated **cholesterol** and **triglycerides**, increasing cardiovascular risk.

Obstructive sleep apnoea: More common in women with **PCOS**, especially those who are **obese**.

Summary of Key Points for PCOS and Hirsutism:

PCOS is diagnosed using the **Rotterdam criteria**, which require two of three features: **anovulation**, **hyperandrogenism**, and **polycystic ovaries**.

First-line treatment for PCOS includes **lifestyle modifications**, the **COC**, **anti-androgens** (e.g., **spironolactone**), and **metformin** for insulin resistance.

148. Hyperlipidaemia

1. Detailed Definition of Hyperlipidaemia:

Hyperlipidaemia refers to **elevated levels of lipids (fats)** in the blood, primarily **cholesterol** and **triglycerides**. It is a major risk factor for developing **atherosclerosis**, which can lead to **cardiovascular diseases (CVD)** such as **coronary artery disease (CAD)**, **stroke**, and **peripheral vascular disease**.

The condition is usually classified into:

Primary hyperlipidaemia: Due to genetic factors (e.g., familial hypercholesterolaemia).

Secondary hyperlipidaemia: Associated with lifestyle factors or medical conditions (e.g., diabetes, hypothyroidism).

2. Common Presenting Complaints and Symptoms:

Hyperlipidaemia itself often does not present with symptoms and is typically detected through routine blood tests. However, when symptoms do occur, they are usually related to **complications of atherosclerosis** or rarely, **extremely high lipid levels**. Common signs and complications include:

Xanthomas: Yellowish deposits of cholesterol-rich material seen in tendons or under the skin, especially in **familial hypercholesterolaemia**.

Xanthelasma: Yellowish patches around the eyelids.

Corneal arcus: A grey or white arc visible around the cornea, which may suggest hyperlipidaemia in younger patients.

Angina or myocardial infarction: Due to **coronary artery disease**.

Stroke or transient ischaemic attack (TIA): Due to **cerebrovascular disease**.

Pancreatitis: Can occur with extremely elevated **triglyceride** levels (usually >10 mmol/L).

3. First-Line Investigations:

a) Blood Lipid Profile:

Total cholesterol: Desirable level is <5 mmol/L.

Low-density lipoprotein (LDL) cholesterol: Often referred to as "bad cholesterol". Target levels for patients at high cardiovascular risk are <2.5 mmol/L.

High-density lipoprotein (HDL) cholesterol: Known as "good cholesterol". Desirable level is >1 mmol/L.

Triglycerides: Desirable level is <1.7 mmol/L.

b) Fasting or Non-Fasting Lipid Profile:

Recent guidelines allow for **non-fasting lipid profiles** in many cases, but fasting profiles are preferred if **triglycerides** are of particular concern (e.g., in suspected familial hypertriglyceridaemia).

c) Blood Tests to Rule Out Secondary Causes:

Fasting glucose or HbA1c: To check for **diabetes**.

Thyroid function tests (TFTs): To rule out **hypothyroidism**, a common secondary cause of hyperlipidaemia.

Liver function tests (LFTs): To check for **non-alcoholic fatty liver disease (NAFLD)**, which is often associated with dyslipidaemia.

Renal function tests: To rule out **chronic kidney disease**, which can cause secondary hyperlipidaemia.

4. Explanation of Investigations:

Lipid profile: Measures the levels of **cholesterol** and **triglycerides** in the blood, which are central to the diagnosis and management of hyperlipidaemia. Elevated **LDL cholesterol** and **triglycerides** are particularly concerning for cardiovascular risk, while **HDL cholesterol** offers some protective effect.

5. Diagnosis Criteria for Hyperlipidaemia:

Hyperlipidaemia is diagnosed based on **blood lipid levels**. The diagnosis can be confirmed if lipid levels are persistently elevated on more than one occasion, especially after addressing any secondary causes (e.g., hypothyroidism or diabetes). Key thresholds are:

Total cholesterol >5 mmol/L.

LDL cholesterol >3 mmol/L.

Triglycerides >1.7 mmol/L.

For **familial hypercholesterolaemia**, consider a diagnosis if:

Total cholesterol >7.5 mmol/L and/or **LDL** >4.9 mmol/L in adults.

Family history of **premature cardiovascular disease**.

6. First-Line Therapy According to Guidelines:

a) Lifestyle Modifications:

Lifestyle changes are the first-line management for all patients with hyperlipidaemia, regardless of the lipid levels.

Dietary changes:

Reduce saturated fat intake (e.g., processed foods, red meat).

Increase **unsaturated fats** (e.g., oily fish, nuts).

Incorporate **plant stanols/sterols** and **fibre** into the diet.

Reduce alcohol consumption, particularly for those with high triglycerides.

Exercise: Encourage at least **150 minutes of moderate-intensity aerobic activity** per week.

Weight loss: For overweight patients, aim for gradual weight loss to lower lipid levels and reduce cardiovascular risk.

Smoking cessation: Smoking exacerbates cardiovascular risk and should be stopped.

b) Pharmacological Treatment:

The **NICE guidelines** (2014) recommend pharmacological treatment for patients at **high risk of cardiovascular disease** or those with persistently high lipid levels despite lifestyle changes.

Statins (First-line pharmacotherapy):

Atorvastatin 20mg daily for primary prevention in patients with a **QRISK $\geq 10\%$** (10-year cardiovascular risk).

For **secondary prevention** (i.e., patients with established CVD), **atorvastatin 80mg** is recommended.

Mechanism of action: Statins inhibit **HMG-CoA reductase**, reducing **cholesterol synthesis** in the liver, thereby lowering LDL cholesterol.

Ezetimibe:

Monotherapy or **add-on** to statins for patients intolerant to statins or those who cannot reach lipid targets with statins alone.

Mechanism of action: Reduces **cholesterol absorption** in the intestines.

Fibrates:

Used in patients with **elevated triglycerides**, particularly those with **triglycerides >4.5 mmol/L**.

Mechanism of action: Lowers **triglyceride** levels by activating **PPAR-alpha**, increasing lipid metabolism.

PCSK9 inhibitors:

Considered for patients with **familial hypercholesterolaemia** or those at **very high cardiovascular risk** who cannot tolerate statins or reach LDL cholesterol targets despite treatment.

Examples include **evolocumab** and **alirocumab**.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Statins: Contraindicated in patients with **active liver disease** or during **pregnancy**.

Fibrates: Contraindicated in patients with **severe renal impairment** or **hepatic dysfunction**.

b) Second-Line Therapy:

Ezetimibe: Used if patients cannot tolerate statins due to side effects (e.g., muscle pain).

PCSK9 inhibitors: Used as add-on therapy in patients who fail to achieve LDL cholesterol targets with maximally tolerated statin therapy.

8. Routine Monitoring and Follow-Up:

Lipid profile:

Monitor **lipid levels** after **3 months** of starting treatment to assess response, then **annually** if stable.

Liver function tests (LFTs):

Monitor **LFTs** before starting statins, then 3 months after initiation, and again at **12 months** to check for **statin-induced hepatotoxicity**.

Blood glucose:

Monitor for the development of **diabetes** in patients on long-term **statin therapy**, especially those at high risk of diabetes.

Creatine kinase (CK):

Monitor in patients who develop **muscle pain** on statins to assess for **statin-induced myopathy**.

9. Complications of Hyperlipidaemia:

Cardiovascular disease: The most significant risk, leading to **myocardial infarction**, **stroke**, and **peripheral vascular disease**.

Pancreatitis: Caused by extremely elevated **triglyceride levels**, especially >10 mmol/L.

Atherosclerosis: Progressive **arterial plaque formation** can lead to **angina**, **claudication**, or **renal artery stenosis**.

Summary of Key Points for Hyperlipidaemia:

Hyperlipidaemia is characterised by elevated **cholesterol** or **triglyceride levels**, contributing to **atherosclerosis** and **cardiovascular disease**.

Diagnosis is based on **lipid profile**, with elevated **LDL cholesterol** and **triglycerides** posing significant cardiovascular risk.

First-line treatment includes **lifestyle modifications** (diet, exercise, weight loss), followed by **statins** as pharmacological therapy.

Monitoring involves **lipid levels**, **LFTs**, and **glucose**, with regular follow-up to assess treatment efficacy and side effects.

149. Obesity

1. Detailed Definition of Obesity:

Obesity is a condition characterised by **excess body fat** that can negatively impact health. It is commonly assessed using **Body Mass Index (BMI)**, which is a measure of weight in relation to height. In adults, obesity is classified as follows:

- **Overweight:** BMI between 25 and 29.9 kg/m²
- **Obese:** BMI ≥ 30 kg/m²
- **Severely obese:** BMI ≥ 35 kg/m²
- **Morbidly obese:** BMI ≥ 40 kg/m²

Obesity is a major risk factor for a wide range of **chronic conditions**, including **cardiovascular disease**, **type 2 diabetes**, **osteoarthritis**, and some types of cancer.

2. Common Presenting Complaints and Symptoms:

Obesity itself may not present with direct symptoms but is often linked with comorbid conditions and related complications. **Common presentations** include:

- **Weight gain** and **difficulty losing weight**.
- **Breathlessness** and **exercise intolerance**.
- **Fatigue** and **lethargy**.
- **Joint pain** and **osteoarthritis**, particularly in weight-bearing joints (e.g., knees, hips).
- **Snoring** and **obstructive sleep apnoea**.
- **Gastroesophageal reflux** or heartburn.
- **Menstrual irregularities** or **infertility** in women.
- **Psychological distress**, including **low self-esteem** and **depression**.

3. First-Line Investigations:

a) BMI and Waist Circumference:

- **BMI:** A key measure of **adiposity** calculated by dividing weight (kg) by height (m²). A BMI ≥ 30 kg/m² indicates obesity.
- **Waist circumference:** Provides additional information on **abdominal fat distribution**. Waist circumference greater than **94 cm** in men and **80 cm** in women indicates an increased risk of **metabolic complications**.

b) Blood Tests:

- **Lipid profile:** To assess for **dyslipidaemia**, including raised **cholesterol** and **triglycerides**.
- **Fasting glucose or HbA1c:** To screen for **type 2 diabetes mellitus** or prediabetes.
- **Liver function tests (LFTs):** To check for **non-alcoholic fatty liver disease (NAFLD)**, which is common in obesity.
- **Thyroid function tests (TFTs):** To rule out **hypothyroidism** as a cause of weight gain.
- **C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR):** To assess for inflammation, which is often elevated in obesity.

4. Explanation of Investigations:

- **BMI:** A simple measure of obesity but does not account for muscle mass. It is often combined with **waist circumference** to assess central obesity and associated risks of **cardiovascular disease** and **type 2 diabetes**.
- **Lipid profile:** Elevated levels of **LDL cholesterol** and **triglycerides** are common in obesity and increase the risk of atherosclerosis and cardiovascular events.

5. Diagnosis Criteria for Obesity:

Obesity is diagnosed primarily based on **BMI** and is further assessed using **waist circumference** to determine the risk of associated **metabolic complications**.

Obesity classification (according to BMI):

- **Normal weight:** BMI 18.5–24.9 kg/m²
- **Overweight:** BMI 25–29.9 kg/m²
- **Obesity Class I (Moderate):** BMI 30–34.9 kg/m²
- **Obesity Class II (Severe):** BMI 35–39.9 kg/m²
- **Obesity Class III (Morbid):** BMI ≥ 40 kg/m²

6. First-Line Therapy According to Guidelines:

NICE guidelines for the management of obesity focus on **lifestyle interventions**, **pharmacological treatment**, and **bariatric surgery**.

a) Lifestyle Interventions:

- **Dietary changes:** Reduce caloric intake through a **balanced, calorie-controlled diet**. A typical recommendation is to reduce daily intake by **500-600 kcal** to induce weight loss of **0.5-1 kg per week**.
 - **Low-fat, low-sugar, and high-fibre** foods are recommended.
 - Include **whole grains, fruits, vegetables, lean proteins, and healthy fats**.
- **Physical activity:** Encourage at least **150 minutes of moderate-intensity aerobic activity** (e.g., brisk walking, swimming) per week. Strength training exercises are also recommended.

- **Behavioural therapy:** Cognitive-behavioural therapy (CBT) or **motivational interviewing** may help with **goal setting, habit formation**, and managing **emotional eating**.

b) Pharmacological Treatment:

Medication is indicated for patients with **BMI ≥ 30 kg/m²** or **BMI ≥ 27 kg/m²** with associated comorbidities.

- **Orlistat** (120 mg three times daily): An **intestinal lipase inhibitor** that prevents the absorption of dietary fat by about 30%. It is used as an adjunct to lifestyle changes.
 - **Common side effects:** Gastrointestinal disturbances such as **steatorrhoea** (fatty stools) and **diarrhoea**.

c) Bariatric Surgery:

Bariatric surgery may be considered for patients with **BMI ≥ 40 kg/m²** or **BMI ≥ 35 kg/m²** with significant comorbidities who have not achieved adequate weight loss with other interventions.

- **Types of bariatric surgery:**
 - **Gastric banding:** A band is placed around the stomach to reduce its size.
 - **Gastric bypass:** The stomach is divided into a small pouch that is connected directly to the small intestine, bypassing most of the stomach.
 - **Sleeve gastrectomy:** A portion of the stomach is removed to reduce its size.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Orlistat:** Contraindicated in patients with **chronic malabsorption syndromes** and **cholestasis**.
- **Bariatric surgery:** Contraindicated in patients with **severe psychiatric illness**, **uncontrolled substance abuse**, or **conditions that increase surgical risk**.

b) Second-Line Therapy:

- For patients who fail to respond to **orlistat** or **lifestyle interventions**, consider referral for **bariatric surgery** or additional pharmacological options under specialist care.
- **Liraglutide:** A **GLP-1 agonist** used for weight management may be prescribed if first-line treatments are ineffective. It works by increasing **satiety** and slowing gastric emptying.

8. Routine Monitoring and Follow-Up:

1. Weight Monitoring:

- Regular monitoring of weight, ideally **every 4–6 weeks** to assess progress.

2. Blood Tests:

- **Lipid profile** and **HbA1c** should be checked regularly to monitor the impact of weight loss on **cholesterol** and **blood glucose levels**.

3. Blood Pressure:

- Monitoring for improvement or control of **hypertension**, which is common in obesity.

4. Nutritional Status:

- After **bariatric surgery**, monitor for **micronutrient deficiencies**, especially **iron**, **vitamin B12**, **calcium**, and **vitamin D**.

9. Complications of Obesity:

- **Cardiovascular disease:** Increased risk of **hypertension**, **coronary artery disease**, and **stroke**.
- **Type 2 diabetes:** Strongly associated with obesity due to **insulin resistance**.
- **Non-alcoholic fatty liver disease (NAFLD):** Can progress to **non-alcoholic steatohepatitis (NASH)** and **cirrhosis**.
- **Obstructive sleep apnoea:** Can lead to **daytime fatigue** and **cardiovascular complications**.
- **Osteoarthritis:** Particularly in weight-bearing joints like the knees and hips.
- **Psychological impact:** Obesity can contribute to **depression**, **anxiety**, and **low self-esteem**.

Summary of Key Points for Obesity:

- **Obesity** is defined by a **BMI $\geq 30 \text{ kg/m}^2$** and is associated with a range of **chronic conditions** such as **cardiovascular disease**, **type 2 diabetes**, and **osteoarthritis**.
- The first-line treatment for obesity involves **lifestyle changes**, including **dietary modifications** and **increased physical activity**.
- **Pharmacological treatments** such as **orlistat** may be considered if lifestyle interventions are insufficient.
- **Bariatric surgery** may be indicated for patients with severe obesity and related comorbidities.
- Regular monitoring and follow-up are essential to assess **weight loss progress** and manage any **comorbid conditions**.

150. Cholesteatoma

1. Detailed Definition of Cholesteatoma

A **cholesteatoma** is an abnormal, non-cancerous growth of keratinising squamous epithelium in the middle ear and mastoid. It can lead to the destruction of nearby structures, including the ossicles, leading to hearing loss, recurrent ear infections, and in severe cases, complications such as facial nerve damage or intracranial infection.

Cholesteatomas can be **congenital** or more commonly **acquired**. Acquired cholesteatomas typically develop as a result of chronic eustachian tube dysfunction, which leads to retraction of the tympanic membrane and the formation of a keratin-filled sac that continues to grow.

2. Common Presenting Complaints and Symptoms

Patients with cholesteatoma may present with:

a) Chronic Ear Discharge (Otorrhoea):

Persistent or recurrent foul-smelling discharge from the affected ear, often resistant to standard treatment for infections.

b) Hearing Loss:

Conductive hearing loss is common due to the erosion of the ossicles (small bones in the middle ear). Sensorineural hearing loss can occur if the inner ear is affected.

c) Ear Fullness or Pressure:

A feeling of fullness or pressure in the affected ear.

d) Tinnitus:

Ringling or buzzing in the ear, often associated with hearing loss.

e) Dizziness or Imbalance:

In more advanced cases, the cholesteatoma may invade the structures of the inner ear, causing vertigo, dizziness, or balance disturbances.

f) Facial Weakness (rare):

In cases where the cholesteatoma affects the facial nerve, patients may experience facial numbness or weakness.

g) Recurrent Ear Infections:

Recurrent otitis media or mastoiditis can occur due to the ongoing presence of the cholesteatoma.

3. First-Line Investigations

Diagnosis of cholesteatoma is based on clinical examination and imaging studies to assess the extent of the disease.

a) **Otoscopy:**

What it examines: Visual inspection of the tympanic membrane.

Purpose: The tympanic membrane may show signs of retraction or perforation, with keratin debris visible in the middle ear. The presence of a retraction pocket or a whitish mass may suggest cholesteatoma.

b) **Pure Tone Audiometry (PTA):**

What it examines: Measures hearing levels.

Purpose: Identifies conductive hearing loss, which is common in cholesteatoma due to ossicular erosion.

c) **High-Resolution CT Scan of the Temporal Bone:**

What it examines: Detailed imaging of the bony structures of the middle ear and mastoid.

Purpose: Confirms the diagnosis by identifying the presence of a soft tissue mass (cholesteatoma) and assesses the extent of bone destruction, including the ossicles, mastoid, and adjacent structures such as the facial nerve or semicircular canals.

d) **MRI Scan (if needed):**

What it examines: Soft tissue structures of the inner ear and surrounding areas.

Purpose: Used to detect complications such as intracranial extension, abscess formation, or involvement of the dura and brain. It is also helpful in differentiating between residual or recurrent cholesteatoma after surgery.

4. Explanation of Investigations

a) **Otoscopy:**

Otoscopy is the first step in diagnosing cholesteatoma. The typical findings include a retracted or perforated tympanic membrane with visible debris or a white mass behind the eardrum. If a cholesteatoma is suspected, further imaging is required.

b) **CT Scan of the Temporal Bone:**

CT imaging provides detailed information about the bony structures of the middle ear and mastoid. It is particularly useful in assessing the extent of bone destruction caused by the cholesteatoma, such as erosion of the ossicles, the mastoid, or the bony covering of the facial nerve and semicircular canals.

5. Diagnostic Criteria for Cholesteatoma

The diagnosis of cholesteatoma is made based on:

Clinical Examination: Otoscopic findings such as retraction pockets, perforation, or the presence of keratin debris behind the tympanic membrane.

Imaging: High-resolution CT scan showing a soft tissue mass with bony destruction in the middle ear or mastoid.

Hearing Loss: Conductive hearing loss on audiometry due to ossicular erosion.

Recurrent or Persistent Otorrhoea: Foul-smelling discharge that persists despite medical treatment for ear infections.

According to **NICE guidelines**, cholesteatoma should be suspected in patients with chronic ear infections, hearing loss, and a retracted or perforated eardrum, and imaging should be performed to confirm the diagnosis.

6. First-Line Therapy According to Guidelines

Cholesteatoma does not resolve on its own and typically requires surgical intervention to prevent further complications.

a) Surgical Removal (Tympanomastoidectomy):

Action: Surgical excision of the cholesteatoma, often involving the removal of the diseased mastoid bone (mastoidectomy) and reconstruction of the middle ear (tympanoplasty).

Purpose: Prevents further complications by completely removing the cholesteatoma and restoring hearing as much as possible.

Outcome: Surgery is generally successful in removing the cholesteatoma, though long-term follow-up is required to detect recurrences.

b) Ossicular Reconstruction (if needed):

Action: Reconstructing the ossicular chain (bones of hearing) during the same procedure or at a later date to improve hearing.

Purpose: Restores conductive hearing loss caused by the destruction of the ossicles.

c) Antibiotic Therapy (pre-surgery):

Action: Oral or topical antibiotics may be given to treat any active infection before surgery.

Purpose: Reduces inflammation and infection, helping to optimise the surgical field.

d) Regular Follow-Up and Surveillance:

Action: After surgery, regular clinical and imaging follow-up is necessary to monitor for recurrence.

Purpose: Recurrence is possible, so long-term monitoring is crucial. MRI may be used for detecting recurrent cholesteatoma.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Surgery in Medically Unfit Patients: In some cases, patients with significant comorbidities or those who are medically unstable may not be suitable candidates for surgery. In such cases, the focus may be on managing symptoms, though this does not address the underlying disease.

b) **Second-Line Therapy:**

Revision Surgery (if needed):

Indication: For patients who experience recurrence of the cholesteatoma after the initial surgery or incomplete removal.

Outcome: Revision surgery may be required to remove residual disease and prevent further complications.

Hearing Aids (for irreversible hearing loss):

Indication: For patients who have persistent conductive hearing loss despite surgical reconstruction.

Outcome: Improves quality of life and communication by amplifying sound to compensate for hearing loss.

8. Routine Monitoring and Follow-Up

a) **Regular Otoscopic Examinations:**

Patients should have regular ear examinations postoperatively to check for signs of recurrence or residual cholesteatoma.

b) **Imaging Surveillance:**

MRI scans are often used to monitor for recurrent cholesteatoma, especially in cases where the initial disease was extensive. Surveillance imaging is typically done at intervals of 6 months to 1 year after surgery.

c) **Audiometric Testing:**

Hearing tests should be performed regularly to assess changes in hearing and the success of ossicular reconstruction or to determine the need for hearing aids.

9. Complications of Cholesteatoma

a) **Hearing Loss:**

Cholesteatoma can erode the ossicles, leading to conductive hearing loss. In advanced cases, the inner ear may be affected, resulting in sensorineural hearing loss.

b) **Facial Nerve Palsy:**

Erosion of the bony covering of the facial nerve can lead to facial weakness or paralysis, which may be permanent if not treated promptly.

c) **Labyrinthitis:**

Spread of the cholesteatoma to the inner ear can cause inflammation, leading to vertigo, balance problems, and hearing loss.

d) **Mastoiditis:**

The cholesteatoma can spread into the mastoid bone, causing infection and destruction of the bone, which can lead to more serious complications.

e) **Intracranial Complications:**

If left untreated, cholesteatomas can extend into the cranial cavity, causing meningitis, brain abscesses, or sigmoid sinus thrombosis, all of which are life-threatening.

Summary of Key Points for Cholesteatoma

Cholesteatoma is a destructive, keratinising growth in the middle ear that can cause hearing loss, recurrent infections, and serious complications if left untreated.

Diagnosis is made via **otoscopy** and confirmed by a **CT scan of the temporal bone**.

Surgical removal is the mainstay of treatment, with **tympanomastoidectomy** being the most common procedure to excise the cholesteatoma and reconstruct the middle ear.

Long-term **monitoring** is essential due to the risk of recurrence, with regular otoscopic examinations and MRI scans as part of follow-up care.

151. Epiglottitis

1. Detailed Definition of Epiglottitis

Epiglottitis is an acute and potentially life-threatening infection and inflammation of the epiglottis, a flap of cartilage at the base of the tongue that covers the trachea during swallowing to prevent food from entering the airway. When inflamed, the epiglottis can swell rapidly, leading to airway obstruction.

Epiglottitis was historically more common in children due to **Haemophilus influenzae type B (Hib)** infection, but widespread vaccination has reduced its incidence. However, epiglottitis still occurs in adults, often caused by bacteria, trauma, or thermal injury (e.g., burns from hot liquids or food).

2. Common Presenting Complaints and Symptoms

Patients with epiglottitis typically present with rapidly progressing symptoms, including:

a) **Sore Throat and Odynophagia (Painful Swallowing):**

Severe throat pain disproportionate to findings on initial examination.

b) **Stridor:**

A high-pitched, wheezing sound during breathing, indicating airway obstruction. It is often inspiratory and worsens as the airway becomes more obstructed.

c) **Drooling:**

Due to difficulty swallowing, patients may drool excessively, particularly in children.

d) Muffled or "Hot Potato" Voice:

The voice may sound muffled or thick, often described as a "hot potato" voice, as swelling of the epiglottis affects speech.

e) Tripod Position:

Patients may sit leaning forward, with their hands on their knees, to help open the airway and facilitate breathing.

f) Respiratory Distress:

Tachypnoea (rapid breathing), use of accessory muscles, and nasal flaring are signs of respiratory distress and potential impending airway obstruction.

g) Fever:

High-grade fever is common in cases caused by bacterial infection.

h) Cyanosis (late sign):

Bluish discolouration of the skin and lips, a late sign of significant airway compromise.

3. First-Line Investigations

Epiglottitis is primarily a clinical diagnosis, and rapid assessment is crucial. Investigations should not delay securing the airway in patients with severe respiratory distress. Key investigations include:

a) Laryngoscopy (in a controlled environment):

What it examines: Direct visualisation of the epiglottis.

Purpose: Confirms the diagnosis of epiglottitis by showing an inflamed, swollen, and cherry-red epiglottis. This should only be performed in a controlled setting, such as an operating room, where immediate airway management is available if needed.

b) Lateral Neck X-ray:

What it examines: Soft tissue structures of the neck.

Purpose: May show the classic "thumbprint sign" due to swollen epiglottis. While this is a useful diagnostic tool in patients with stable airways, it is not always necessary if the clinical picture is clear.

c) Blood Cultures:

What it examines: Detects the presence of bacterial pathogens in the blood.

Purpose: Confirms the causative organism, particularly in patients with suspected sepsis or systemic infection.

d) Throat Swab or Epiglottis Culture (post airway management):

What it examines: Cultures for bacterial growth.

Purpose: Identifies the causative organism, particularly **Haemophilus influenzae type B**, though other bacteria, such as **Streptococcus pneumoniae**, may also be implicated.

e) Pulse Oximetry and Arterial Blood Gas (ABG):

What it examines: Oxygen saturation and blood gas levels.

Purpose: Monitors respiratory function and identifies hypoxia or hypercapnia in patients with airway compromise.

4. Explanation of Investigations

a) Laryngoscopy:

This is the gold standard for diagnosing epiglottitis. In severe cases, direct visualisation of the swollen epiglottis confirms the diagnosis. However, this procedure is only performed when airway management (e.g., intubation or tracheostomy) is immediately available, as manipulation of the airway can precipitate complete obstruction.

b) Lateral Neck X-ray:

A lateral neck X-ray may show the "thumbprint sign," an enlarged epiglottis that resembles the shape of a thumbprint. While helpful in supporting the diagnosis, an X-ray should not delay airway management in a patient with signs of severe respiratory distress.

5. Diagnostic Criteria for Epiglottitis

The diagnosis of epiglottitis is clinical, based on:

Acute onset of sore throat, odynophagia, stridor, and drooling.

Airway compromise indicated by stridor, tachypnoea, and respiratory distress.

Laryngoscopic findings of an inflamed, swollen, cherry-red epiglottis.

Lateral neck X-ray showing the "thumbprint sign" in patients with milder cases or stable airways.

According to **NICE guidelines**, epiglottitis is a medical emergency, and the priority is securing the airway. Diagnostic tests such as laryngoscopy or imaging should not delay treatment.

6. First-Line Therapy According to Guidelines

Management of epiglottitis is focused on securing the airway and treating the underlying infection. Immediate treatment includes:

a) Airway Management (priority):

Action: Early intubation or tracheostomy may be required if there are signs of impending airway obstruction (e.g., severe stridor, respiratory distress, or hypoxia). Patients should be managed in an intensive care unit (ICU) or operating room setting where experienced personnel can secure the airway.

Outcome: Prevents life-threatening airway obstruction.

b) Intravenous Broad-Spectrum Antibiotics:

Action: Empirical antibiotic therapy targeting common causative organisms, including **Haemophilus influenzae type B (Hib)**, **Streptococcus pneumoniae**, and **Staphylococcus aureus**.

Ceftriaxone or **Cefotaxime:** 50-100 mg/kg/day IV divided every 12 hours.

Ampicillin-sulbactam or **cefuroxime** may also be used.

Outcome: Treats the underlying bacterial infection. Once the organism is identified through cultures, antibiotic therapy can be adjusted accordingly.

c) Steroids (controversial):

Action: Corticosteroids such as **dexamethasone** may be given to reduce airway swelling and inflammation, though their use is debated.

Dose: Dexamethasone 0.6 mg/kg IV, typically a one-time dose.

Outcome: May reduce airway oedema, although evidence for routine use is limited.

d) IV Fluids:

Action: IV fluids are given to maintain hydration, especially if the patient is unable to swallow due to severe pain or swelling.

Outcome: Prevents dehydration and supports the patient while oral intake is restricted.

e) Humidified Oxygen Therapy:

Action: Administered to patients with hypoxia or respiratory distress while awaiting airway intervention.

Outcome: Maintains oxygenation and reduces the risk of hypoxia-induced complications.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Throat Examination in Unstable Patients: In patients with severe airway compromise, any manipulation of the airway (e.g., using a tongue depressor to examine the throat) may cause complete obstruction and should be avoided until the airway is secured.

b) Second-Line Therapy:

Surgical Tracheostomy:

Indication: For patients in whom intubation is not possible or in cases of complete airway obstruction.

Outcome: Provides an alternate airway in emergencies where intubation fails or is contraindicated.

Tailored Antibiotic Therapy:

Indication: Once culture results are available, antibiotics can be tailored to target the specific pathogen.

Outcome: Improves efficacy of treatment and reduces the risk of antibiotic resistance.

8. Routine Monitoring and Follow-Up

a) ICU Monitoring:

Patients with severe epiglottitis should be monitored in the ICU for signs of airway obstruction, hypoxia, and sepsis. Regular checks of respiratory function and vital signs are essential.

b) Response to Antibiotics:

Monitor clinical improvement, including reduction in fever, improvement in swallowing, and resolution of airway symptoms, to assess the efficacy of antibiotics.

c) Follow-up After Discharge:

Patients, particularly children, should have follow-up appointments to ensure that symptoms have fully resolved. Vaccination status should be reviewed, especially for **Hib** vaccination in children who were not previously immunised.

9. Complications of Epiglottitis

a) Airway Obstruction:

The most dangerous complication of epiglottitis is complete airway obstruction, which can occur rapidly and without warning, leading to asphyxia and death if not treated immediately.

b) Sepsis and Septic Shock:

In cases of bacterial epiglottitis, the infection can spread systemically, leading to sepsis and septic shock, which require aggressive treatment.

c) Pneumonia and Pulmonary Complications:

Aspiration pneumonia or other pulmonary infections may develop, especially in patients with prolonged intubation or those who aspirate due to swallowing difficulties.

d) Abscess Formation:

An abscess can form in the epiglottis or surrounding structures, leading to further complications that may require drainage.

Summary of Key Points for Epiglottitis

Epiglottitis is a medical emergency characterised by rapid-onset sore throat, odynophagia, and airway obstruction symptoms such as stridor and drooling.

Immediate airway management is the priority, with early intubation or tracheostomy in patients showing signs of respiratory distress.

Empirical antibiotics (e.g., ceftriaxone) are the mainstay of treatment, targeting common bacterial pathogens like **Haemophilus influenzae**.

Regular monitoring for signs of airway compromise and sepsis is essential, and patients require close follow-up after recovery.

152. Epistaxis

1. Detailed Definition of Epistaxis

Epistaxis, commonly known as a nosebleed, is the acute bleeding from the nasal cavity. It can originate from the anterior or posterior part of the nasal cavity:

Anterior epistaxis: The most common type, typically arising from the rich vascular network in **Kiesselbach's plexus** (Little's area), located on the anterior part of the nasal septum.

Posterior epistaxis: Less common but more serious, it originates from branches of the **sphenopalatine artery** and is more likely to require medical intervention due to the risk of significant blood loss and the difficulty of accessing the bleeding source.

Epistaxis is usually self-limiting but can sometimes become life-threatening, particularly in the elderly or in patients with coagulopathies or significant comorbidities.

2. Common Presenting Complaints and Symptoms

Patients with epistaxis typically present with the following:

a) **Visible Bleeding:**

Bright red blood flowing from one or both nostrils. It can be continuous or intermittent and may be worsened by blowing the nose.

b) **Nasal Congestion:**

Sensation of nasal fullness or congestion due to clotted blood within the nasal cavity.

c) **Blood in the Throat or Mouth:**

In posterior epistaxis, blood may trickle down the throat, leading to swallowing of blood and possibly haematemesis (vomiting of blood).

d) **Dizziness or Weakness:**

May occur in patients with significant blood loss or prolonged bleeding, especially in elderly patients.

e) **Symptoms of Underlying Conditions:**

Patients with conditions like hypertension, blood disorders, or anticoagulant use may present with persistent or recurrent episodes.

3. First-Line Investigations

Diagnosis of epistaxis is primarily clinical, but certain investigations may be needed to assess the severity of bleeding and any underlying causes.

a) Anterior Rhinoscopy:

What it examines: Visual inspection of the nasal cavity with a speculum and light.

Purpose: Identifies the source of anterior bleeding, usually from Kiesselbach's plexus.

b) Posterior Rhinoscopy:

What it examines: Examination of the posterior nasal cavity using a flexible or rigid endoscope.

Purpose: Identifies the source of posterior bleeding, which is harder to visualise and manage.

c) Full Blood Count (FBC):

What it measures: Haemoglobin, haematocrit, platelet count, and white blood cell count.

Purpose: Assesses for anaemia due to significant blood loss and checks for thrombocytopenia or underlying haematological conditions that may contribute to bleeding.

d) Coagulation Profile (PT/INR, aPTT):

What it measures: Prothrombin time (PT), International Normalised Ratio (INR), and activated partial thromboplastin time (aPTT).

Purpose: Evaluates clotting function, particularly in patients on anticoagulants (e.g., warfarin) or with coagulopathies.

e) Blood Pressure Monitoring:

What it examines: Blood pressure levels.

Purpose: Identifies hypertension, a common contributing factor to epistaxis, particularly in elderly patients.

f) Imaging (if needed):

What it examines: CT scan of the sinuses or head.

Purpose: Rarely indicated but may be necessary if there is suspicion of trauma, tumours, or foreign bodies contributing to the epistaxis.

4. Explanation of Investigations

a) Anterior Rhinoscopy:

In the majority of cases, epistaxis originates from the anterior part of the nasal septum, and visual inspection using a nasal speculum is often sufficient to locate the bleeding source. This allows targeted management such as cauterisation or packing.

b) Coagulation Profile:

A coagulation profile is particularly important in patients on anticoagulants (e.g., warfarin or direct oral anticoagulants) or those with known clotting disorders. It helps guide the reversal of anticoagulation if needed.

5. Diagnostic Criteria for Epistaxis

The diagnosis of epistaxis is made based on:

Visible nasal bleeding: Blood from one or both nostrils or from the mouth/throat in posterior epistaxis.

Identifiable bleeding source: In anterior epistaxis, visual confirmation of bleeding from the nasal septum (Kiesselbach's plexus) via rhinoscopy. In posterior epistaxis, bleeding is typically more diffuse and may require endoscopy for visualisation.

Exclusion of trauma or underlying causes: In cases of recurrent or severe epistaxis, investigations to exclude trauma, neoplasms, coagulopathies, or vascular malformations should be considered.

6. First-Line Therapy According to Guidelines

The management of epistaxis is based on controlling the bleeding and addressing any underlying causes or risk factors. Treatment differs depending on whether the bleeding is anterior or posterior.

Anterior Epistaxis:

a) First Aid Measures:

Action: Pinching the soft part of the nose for 10-15 minutes while the patient leans forward (to avoid swallowing blood).

Outcome: Often sufficient to stop mild cases of anterior epistaxis.

b) Topical Vasoconstrictors:

Action: Application of topical vasoconstrictors such as **oxymetazoline** or **adrenaline** to constrict blood vessels and reduce bleeding.

Outcome: Helps control mild to moderate anterior bleeding.

c) Cauterisation (if bleeding site visible):

Action: Chemical cauterisation using **silver nitrate** or electrical cautery.

Outcome: Cauterisation seals off the bleeding vessel and is highly effective in controlling anterior epistaxis.

d) Nasal Packing:

Action: Nasal packing using gauze or nasal tampons impregnated with vasoconstrictive agents.

Outcome: Used when cauterisation is ineffective or the bleeding source is not identifiable. Packing applies direct pressure to the bleeding site.

Posterior Epistaxis:

a) Posterior Nasal Packing:

Action: Nasal balloons (e.g., Rapid Rhino or Foley catheters) or gauze packing applied to the posterior nasal cavity to tamponade the bleeding.

Outcome: Controls bleeding from posterior sources but may require sedation or anaesthesia due to discomfort.

b) **Arterial Ligation or Embolisation** (for refractory cases):

Action: Surgical ligation of the sphenopalatine or other feeding arteries, or embolisation via interventional radiology.

Outcome: Reserved for severe or recurrent epistaxis that does not respond to conservative measures.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Nasal Packing in Suspected Skull Fracture: Nasal packing should be avoided in patients with head trauma and suspected skull base fractures due to the risk of further injury and infection.

b) **Second-Line Therapy:**

Surgical Ligation (if nasal packing fails):

Indication: For patients with recurrent or intractable posterior epistaxis that is unresponsive to packing or medical management.

Outcome: Direct surgical ligation of the sphenopalatine artery or other bleeding vessels effectively stops bleeding in most cases.

Embolisation:

Indication: For patients unfit for surgery or those with recurrent bleeding despite surgical intervention.

Outcome: Embolisation via interventional radiology can block the blood supply to the bleeding area, reducing the risk of rebleeding.

8. Routine Monitoring and Follow-Up

a) **Monitoring in Hospital:**

Patients with significant epistaxis, particularly those requiring posterior packing, should be monitored for signs of rebleeding, infection, or airway compromise. Continuous monitoring of vital signs and oxygenation is essential.

b) **Blood Pressure Control:**

Hypertension is a common contributor to epistaxis, and patients should have their blood pressure monitored and controlled, both during an acute episode and long-term.

c) **Follow-Up for Anticoagulant Use:**

Patients on anticoagulants may require dose adjustment or temporary cessation. Long-term follow-up with their prescribing physician is essential to balance the risk of bleeding and thrombosis.

9. Complications of Epistaxis

a) Hypovolemic Shock:

Significant blood loss from severe or recurrent epistaxis can lead to hypovolemic shock, particularly in elderly or frail patients. This requires fluid resuscitation and, in some cases, blood transfusions.

b) Recurrent Epistaxis:

Patients with underlying causes such as hypertension, coagulopathies, or nasal pathologies may experience recurrent episodes of epistaxis, requiring ongoing monitoring and treatment.

c) Infection:

Nasal packing, particularly posterior packing, can increase the risk of infection, including sinusitis and toxic shock syndrome, necessitating prophylactic antibiotics in some cases.

d) Airway Compromise:

In cases of severe posterior epistaxis, blood can obstruct the airway or lead to aspiration, particularly if the patient is sedated or has impaired consciousness.

Summary of Key Points for Epistaxis

Epistaxis is most commonly caused by bleeding from the anterior part of the nasal septum (Kiesselbach's plexus) but can also originate from posterior sources, which are more serious.

Diagnosis is based on visualisation of the bleeding site through **rhinoscopy** or endoscopy.

First-line treatments for **anterior epistaxis** include simple first aid (nasal pinching), **topical vasoconstrictors**, and **cauterisation**, while **posterior epistaxis** often requires **posterior nasal packing** or **surgical intervention**.

Recurrent or severe cases should be investigated for underlying causes such as hypertension, anticoagulant use, or nasal pathology, and **blood pressure management** is essential in preventing recurrences.

153. Foreign Body

1. Detailed Definition of Foreign Body in ENT

A **foreign body** in the ear, nose, or throat refers to any object that is lodged in the ear canal, nasal cavity, or oropharynx that does not belong there. This is a common issue, particularly in children, but can also occur in adults, especially in cases of trauma, accidents, or inhalation.

Ear: Objects such as beads, insects, cotton swabs, or small toys.

Nose: Small objects like beads, seeds, or pebbles, most often seen in children.

Throat: Objects such as fish bones, small toys, dentures, or food particles that may become lodged in the pharynx or airway, posing a risk for airway obstruction.

2. Common Presenting Complaints and Symptoms

The symptoms of a foreign body depend on its location (ear, nose, or throat) and the duration it has been present.

Foreign Body in the Ear:

Ear Pain (Otalgia): Pain may be due to pressure on the ear canal or eardrum.

Hearing Loss: Conductive hearing loss can occur if the object obstructs the ear canal.

Discharge or Foul Odour: Prolonged presence of a foreign body may cause infection, leading to purulent or foul-smelling discharge.

Tinnitus: Ringing or buzzing in the ear.

Vertigo: In rare cases, if the object affects the inner ear structures.

Foreign Body in the Nose:

Unilateral Nasal Discharge: Foul-smelling discharge from one nostril, often a sign of a retained foreign body, particularly in children.

Nasal Obstruction: Difficulty breathing through one side of the nose.

Epistaxis (Nosebleed): Bleeding may occur if the object causes trauma to the nasal mucosa.

Sneezing or Discomfort: Persistent irritation or sneezing due to the foreign body.

Foreign Body in the Throat:

Difficulty Swallowing (Dysphagia): Pain or discomfort when swallowing, particularly if the object is lodged in the pharynx or oesophagus.

Droping: May indicate an obstructing foreign body in the oropharynx.

Choking or Gagging: If the object obstructs the airway or esophagus.

Coughing or Wheezing: Suggests that the foreign body may be in the trachea or bronchi, particularly if inhaled.

Hoarseness or Voice Changes: If the object affects the vocal cords or larynx.

3. First-Line Investigations

Diagnosis of a foreign body is usually clinical, based on patient history and physical examination. However, imaging or endoscopic investigations may be necessary in some cases.

Foreign Body in the Ear:

a) Otoscopy:

What it examines: Visual inspection of the ear canal.

Purpose: Confirms the presence of a foreign body in the ear canal and assesses for any associated trauma or infection.

Foreign Body in the Nose:

b) Anterior Rhinoscopy or Nasal Endoscopy:

What it examines: Visual inspection of the nasal cavity.

Purpose: Identifies the foreign body and assesses for associated complications, such as mucosal damage or infection.

Foreign Body in the Throat:

c) Laryngoscopy or Flexible Nasopharyngoscopy:

What it examines: The oropharynx, hypopharynx, and larynx using a flexible or rigid endoscope.

Purpose: Confirms the presence of a foreign body in the throat or airway, particularly when symptoms of dysphagia, choking, or hoarseness are present.

d) Lateral Neck X-ray or Chest X-ray:

What it examines: Soft tissue of the neck or chest structures.

Purpose: Detects radio-opaque foreign bodies in the throat or oesophagus and assesses for complications like perforation or pneumomediastinum.

e) CT Scan (if needed):

What it examines: Detailed imaging of the head, neck, or chest.

Purpose: Used for non-radio-opaque objects or if there is suspicion of deeper tissue involvement or complications (e.g., abscess, perforation).

4. Explanation of Investigations

a) Otoscopy:

This is the first-line investigation for foreign bodies in the ear. It allows direct visualisation of the foreign object and the surrounding structures, helping to assess whether the object can be removed easily or if there is any associated infection or damage to the ear canal or tympanic membrane.

b) Lateral Neck X-ray:

This is useful for detecting larger, radio-opaque foreign bodies in the throat or oesophagus, particularly in patients with dysphagia or a history of choking. It can also help detect complications such as air or fluid collection, indicating perforation.

5. Diagnostic Criteria for Foreign Body in ENT

The diagnosis of a foreign body is made based on:

History of Foreign Body Insertion or Aspiration: Children may present with a history of placing objects in their ear, nose, or mouth, while adults may present with an incident of choking or difficulty swallowing.

Visualisation: Direct identification of the foreign body via otoscopy, rhinoscopy, or laryngoscopy/endoscopy.

Radiographic Evidence: In cases where the foreign body is not visible on examination, imaging such as X-ray or CT scan may be required, especially for foreign bodies in the airway or gastrointestinal tract.

6. First-Line Therapy According to Guidelines

Treatment of a foreign body in the ear, nose, or throat involves the safe removal of the object and addressing any complications such as infection or trauma. The approach varies depending on the location and nature of the foreign body.

Foreign Body in the Ear:

a) **Ear Irrigation** (for small, non-obstructing objects):

Action: Flushing the ear canal with water or saline.

Outcome: Effective for soft objects or small, non-inflamed foreign bodies, provided there is no risk of perforating the eardrum.

b) **Instrument Removal (e.g., forceps, hook):**

Action: Using specialised tools to carefully remove the foreign body under direct vision with an otoscope or microscope.

Outcome: Effective for objects that are visible and accessible. Should be performed by a skilled practitioner to avoid trauma to the ear canal or eardrum.

Foreign Body in the Nose:

a) **Positive Pressure Techniques:**

Action: Parents or caregivers blow forcefully into the child's mouth while pinching the unaffected nostril (the "parent's kiss" technique).

Outcome: Often successful for small nasal foreign bodies, particularly in children.

b) **Instrument Removal (e.g., forceps or suction):**

Action: Using nasal speculum and forceps or suction to extract the object.

Outcome: Effective for foreign bodies that are visible and easily accessible.

Foreign Body in the Throat:

a) **Endoscopic Removal (Flexible or Rigid Endoscopy):**

Action: Using a flexible or rigid endoscope to visualise and remove the foreign body from the throat or airway.

Outcome: First-line treatment for objects lodged in the throat, oesophagus, or airway. Immediate intervention is required if there is a risk of airway obstruction.

b) **Surgical Removal** (if endoscopy fails or for complicated cases):

Action: Open surgery to remove the foreign body, particularly in cases of deep impaction or complications like perforation or abscess formation.

Outcome: Used in rare cases where the foreign body cannot be removed endoscopically.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Irrigation of Organic Foreign Bodies (e.g., seeds, insects): Organic material, such as beans or seeds, should not be irrigated, as this can cause swelling of the object and make removal more difficult.

Blind Instrumentation: Blind attempts to remove a foreign body in the ear, nose, or throat should be avoided as it increases the risk of pushing the object further in, causing trauma or damage.

b) Second-Line Therapy:

General Anaesthesia (for complicated cases or uncooperative patients):

Indication: For children or patients who are unable to tolerate the procedure while awake, or when the foreign body is difficult to access.

Outcome: Allows safe and controlled removal of the foreign body without distress or injury.

Surgical Exploration (for retained or complicated foreign bodies):

Indication: For deeply embedded or impacted foreign bodies that cannot be removed via endoscopy or if there is evidence of perforation, abscess, or infection.

Outcome: Ensures complete removal of the foreign body and reduces the risk of complications.

8. Routine Monitoring and Follow-Up

a) Post-Removal Examination:

After the foreign body is removed, the area should be re-examined for signs of trauma, infection, or any residual foreign material.

b) Infection Monitoring:

If there was infection at the site of the foreign body, topical or systemic antibiotics may be prescribed, and the patient should be monitored for resolution of the infection.

c) Hearing Assessment (for ear foreign bodies):

Patients who had a foreign body in the ear should undergo audiometry to assess hearing if there is concern about tympanic membrane damage or prolonged occlusion.

9. Complications of Foreign Body in ENT

a) Infection:

Prolonged retention of a foreign body can lead to local infections such as otitis externa, sinusitis, or abscess formation.

b) Airway Obstruction:

Foreign bodies in the throat or airway can cause partial or complete airway obstruction, leading to respiratory distress, hypoxia, or even death if not treated promptly.

c) Trauma to Local Structures:

Improper removal attempts or prolonged presence of a foreign body can lead to trauma to the ear canal, nasal mucosa, or throat, resulting in bleeding, perforation, or permanent damage.

d) Aspiration:

Foreign bodies in the nose or oropharynx can be inhaled into the lower airway, leading to aspiration pneumonia, choking, or lung collapse.

Summary of Key Points for Foreign Body in ENT

Foreign bodies in the ear, nose, or throat are common, particularly in children, and can cause symptoms such as pain, obstruction, infection, or, in the throat, airway compromise.

Diagnosis is made by **visualising the foreign body** through otoscopy, rhinoscopy, or endoscopy, and imaging is used for deeper or non-visible objects.

First-line treatment involves **safe removal** using instruments or positive pressure techniques, and more complex cases may require **endoscopy** or even **surgery**.

Prompt intervention and proper technique are key to avoiding complications such as infection, trauma, or airway obstruction.

154. Head and Neck Carcinoma

1. Detailed Definition of Head and Neck Carcinoma

Head and neck carcinoma refers to a group of cancers that arise from the mucosal surfaces of the head and neck region, including the oral cavity, pharynx, larynx, nasal cavity, paranasal sinuses, and salivary glands. Most head and neck cancers are **squamous cell carcinomas (SCCs)**, which originate from the epithelial lining of these areas.

The major risk factors for head and neck carcinoma include **tobacco use**, **excessive alcohol consumption**, and **human papillomavirus (HPV) infection**, particularly in oropharyngeal cancers. Other risk factors include **Epstein-Barr virus (EBV)** (associated with nasopharyngeal carcinoma), exposure to radiation, and poor oral hygiene.

2. Common Presenting Complaints and Symptoms

The symptoms of head and neck carcinoma vary depending on the location of the tumour but often include:

Oral Cavity:

Non-Healing Ulcer or Sore: Persistent sore or ulcer in the mouth that does not heal, often on the tongue or floor of the mouth.

Pain or Difficulty Swallowing (Odynophagia): Pain during eating or swallowing, particularly with advanced lesions.

Leukoplakia or Erythroplakia: White or red patches in the mouth that do not rub off and may represent precancerous changes.

Loose Teeth: Particularly when there is invasion into the alveolar bone.

Oropharynx (Tonsils, Base of Tongue, Soft Palate):

Sore Throat: Persistent sore throat that may not respond to antibiotics.

Difficulty Swallowing (Dysphagia): Difficulty or pain when swallowing, often associated with the tumour's growth.

Ear Pain (Referred Otalgia): Ear pain without ear disease, typically referred from a tumour in the oropharynx.

Lump in the Neck: Swollen lymph nodes may be the first sign of metastatic spread, particularly with HPV-associated oropharyngeal carcinoma.

Larynx:

Hoarseness: Persistent hoarseness or voice changes, often due to tumour involvement of the vocal cords.

Stridor or Airway Obstruction: Noisy breathing or difficulty breathing if the tumour obstructs the airway.

Cough: Persistent cough that may be associated with aspiration or irritation from the tumour.

Nasopharynx:

Nasal Obstruction or Discharge: Blocked nasal passage or bloody nasal discharge (epistaxis), often unilateral.

Hearing Loss or Ear Fullness: Due to eustachian tube dysfunction or tumour invasion into the middle ear.

Neck Lump: Commonly the first presentation of nasopharyngeal carcinoma due to metastatic spread to cervical lymph nodes.

3. First-Line Investigations

The diagnosis of head and neck carcinoma is confirmed through clinical evaluation, imaging, and biopsy. Investigations aim to identify the primary tumour, assess its extent, and detect any regional or distant metastasis.

a) Clinical Examination:

What it examines: A thorough head and neck examination, including inspection and palpation of the oral cavity, pharynx, larynx, and neck for masses, lesions, or asymmetry.

Purpose: Identifies suspicious lesions that warrant further investigation.

b) Flexible Nasopharyngoscopy or Laryngoscopy:

What it examines: Visualisation of the nasopharynx, oropharynx, larynx, and vocal cords using a flexible or rigid scope.

Purpose: Detects visible tumours, abnormal growths, or other lesions, particularly in areas that are difficult to assess on routine physical examination.

c) Biopsy of Lesion:

What it examines: A tissue sample is taken from the tumour for histopathological analysis.

Purpose: Confirms the diagnosis of carcinoma and identifies the histological subtype (most commonly squamous cell carcinoma).

d) Fine Needle Aspiration Cytology (FNAC) of Neck Lump:

What it examines: Aspiration of cells from an enlarged cervical lymph node.

Purpose: Assesses for metastatic carcinoma when a neck mass is the first presentation of the disease.

e) CT Scan or MRI of Head and Neck:

What it examines: Imaging of the primary tumour and surrounding tissues.

Purpose: Assesses the size, location, and extent of the primary tumour and its invasion into adjacent structures. MRI is useful for detecting soft tissue involvement, while CT is preferred for bony involvement.

f) PET-CT or CT Chest:

What it examines: Whole-body imaging to detect distant metastases.

Purpose: Used for staging and assessing for metastatic disease, especially in advanced cases where distant metastases are suspected.

g) HPV and EBV Testing:

What it examines: HPV status in oropharyngeal cancers and EBV status in nasopharyngeal cancers.

Purpose: Determines the viral association, which has prognostic implications, particularly for HPV-positive oropharyngeal cancers that tend to have a better prognosis.

4. Explanation of Investigations

a) Flexible Nasopharyngoscopy or Laryngoscopy:

This procedure is critical for directly visualising tumours in the nasopharynx, oropharynx, or larynx. It allows for a detailed examination of mucosal surfaces and any suspicious lesions. Lesions detected during the examination can then be biopsied for histopathological analysis.

b) Biopsy of Lesion:

A biopsy provides the definitive diagnosis of head and neck carcinoma, confirming the presence of malignancy and its histological type (e.g., squamous cell carcinoma). It is essential for guiding treatment planning.

5. Diagnostic Criteria for Head and Neck Carcinoma

Diagnosis is based on:

Clinical Features: Persistent symptoms such as hoarseness, non-healing ulcers, dysphagia, neck lumps, or ear pain.

Biopsy Results: Histological confirmation of carcinoma, typically squamous cell carcinoma.

Imaging Findings: Evidence of a primary tumour, local invasion, or metastatic disease on CT, MRI, or PET-CT scans.

Viral Testing: Positive HPV testing in oropharyngeal cancers or EBV in nasopharyngeal cancers may support the diagnosis and help predict prognosis.

According to **NICE guidelines**, a patient presenting with persistent symptoms suspicious for head and neck carcinoma should be referred for urgent evaluation and biopsy.

6. First-Line Therapy According to Guidelines

The treatment of head and neck carcinoma depends on the stage of the disease, the site of the tumour, and the patient's general health. The main treatment modalities are **surgery**, **radiation therapy**, and **chemotherapy**.

Early-Stage Disease (Stage I-II):

a) Surgical Resection:

Action: Removal of the primary tumour with adequate margins.

Outcome: Effective for early-stage cancers with localised disease, particularly in the oral cavity, larynx, and select cases in the oropharynx.

b) Radiotherapy:

Action: High-energy radiation to destroy cancer cells, often used as a primary treatment or postoperatively.

Outcome: Curative for early-stage tumours in the larynx and oropharynx, where surgery may impair function. Also used postoperatively to reduce the risk of local recurrence.

Locally Advanced Disease (Stage III-IV):

c) Chemoradiation:

Action: Combination of chemotherapy (usually **cisplatin**) and radiation therapy to treat advanced tumours.

Outcome: The standard of care for locally advanced head and neck cancers, particularly in patients with unresectable tumours. Chemoradiation improves survival compared to radiation alone.

d) Neck Dissection:

Action: Surgical removal of involved cervical lymph nodes.

Outcome: Performed in cases of nodal metastasis to control regional disease. May be combined with primary tumour resection.

Metastatic Disease:

e) **Palliative Chemotherapy:**

Action: Systemic chemotherapy, often with drugs such as **cisplatin** or **cetuximab** (targeted therapy for EGFR-positive tumours).

Outcome: Improves symptoms and prolongs survival in patients with metastatic or recurrent head and neck cancer.

f) **Immunotherapy (e.g., Pembrolizumab, Nivolumab):**

Action: Immune checkpoint inhibitors that enhance the body's immune response against cancer cells.

Outcome: Used in advanced or recurrent head and neck cancers that express PD-L1, offering improved survival in some cases.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Surgical Resection: Contraindicated in patients with unresectable tumours (e.g., extensive local invasion) or those with poor performance status who cannot tolerate surgery.

Chemoradiation: Patients with significant comorbidities (e.g., severe cardiovascular disease, renal impairment) may not tolerate the side effects of chemoradiation.

b) **Second-Line Therapy:**

Targeted Therapy (e.g., Cetuximab):

Indication: For patients who are not suitable for cisplatin-based chemoradiation, cetuximab (an EGFR inhibitor) can be used in combination with radiation therapy.

Outcome: Offers an alternative for patients who cannot tolerate traditional chemoradiation.

Palliative Care:

Indication: For patients with end-stage disease, palliative care focuses on symptom relief, including pain management, nutritional support, and psychological support.

Outcome: Improves quality of life in patients with terminal disease.

8. Routine Monitoring and Follow-Up

a) **Regular Surveillance:**

Patients should have regular follow-up appointments every 3-6 months for the first two years,

then annually. Surveillance includes clinical examination, imaging (e.g., CT or MRI), and endoscopy to monitor for recurrence or new primary tumours.

b) Nutritional Support:

Due to difficulty swallowing and weight loss, patients often require nutritional support, including dietary supplements, enteral feeding, or speech and swallowing therapy.

c) Speech and Swallowing Rehabilitation:

For patients who have undergone surgery or radiation, rehabilitation therapy is important to restore speech and swallowing function.

9. Complications of Head and Neck Carcinoma

a) Local Recurrence:

Patients with head and neck cancer are at high risk of local recurrence, particularly if margins are positive after surgery or if radiotherapy is not completed.

b) Metastasis:

Regional metastasis to cervical lymph nodes is common. Distant metastasis, particularly to the lungs, bones, and liver, occurs in advanced cases.

c) Airway Obstruction:

Tumours of the larynx or pharynx can obstruct the airway, requiring emergency tracheostomy or airway management.

d) Dysphagia and Malnutrition:

Difficulty swallowing due to tumour invasion or after surgery/radiotherapy can lead to significant weight loss and malnutrition.

e) Radiation Toxicity:

Patients receiving radiotherapy may experience acute and chronic toxicities, including mucositis, xerostomia (dry mouth), dental problems, and fibrosis of the neck muscles.

Summary of Key Points for Head and Neck Carcinoma

Head and neck carcinoma is most commonly squamous cell carcinoma and arises from the mucosal surfaces of the oral cavity, pharynx, larynx, and nasal cavity.

Diagnosis is confirmed by **biopsy** of suspicious lesions, with imaging (CT, MRI) used to assess the tumour's extent and metastasis.

Surgical resection, radiotherapy, and chemoradiation are the main treatments, with immunotherapy and targeted therapies used in advanced cases.

Long-term **surveillance** and **rehabilitation** are crucial due to the high risk of recurrence, functional impairment, and complications from treatment.

155. Infectious Mononucleosis

1. Detailed Definition of Infectious Mononucleosis

Infectious mononucleosis (IM), also known as **glandular fever**, is a viral illness primarily caused by **Epstein-Barr virus (EBV)**, a member of the herpesvirus family. It is characterized by fever, sore throat, swollen lymph nodes, and fatigue. The virus is spread primarily through saliva, which is why it is sometimes colloquially referred to as the "kissing disease." Infectious mononucleosis typically affects adolescents and young adults but can occur at any age.

The infection results in a proliferation of **mononuclear leukocytes** (hence the name), including atypical lymphocytes, and typically resolves over a few weeks, although fatigue can persist for months.

2. Common Presenting Complaints and Symptoms

The classic triad of infectious mononucleosis includes:

a) **Fever:**

Patients often present with low-grade to moderate fever that can last for 1-2 weeks.

b) **Sore Throat (Pharyngitis):**

Severe sore throat with tonsillar enlargement and exudates (white patches), resembling streptococcal tonsillitis.

c) **Swollen Lymph Nodes (Lymphadenopathy):**

Typically affects the posterior cervical lymph nodes but can involve other lymph node groups (e.g., axillary or inguinal).

Other associated symptoms include:

d) **Fatigue:**

A hallmark of infectious mononucleosis, fatigue can be prolonged, lasting several weeks to months even after the acute phase resolves.

e) **Splenomegaly:**

Enlargement of the spleen is common in up to 50% of patients and may lead to an increased risk of splenic rupture.

f) **Hepatomegaly:**

Enlargement of the liver may occur, sometimes associated with mild liver function abnormalities.

g) **Rash:**

Some patients develop a maculopapular rash, particularly if they are mistakenly treated with **amoxicillin** or **ampicillin** for presumed bacterial tonsillitis.

h) **Headache and Malaise:**

Generalised headache, body aches, and malaise are common systemic symptoms.

i) **Jaundice** (occasionally):

In some cases, mild jaundice may develop due to transient liver dysfunction.

3. First-Line Investigations

Diagnosis of infectious mononucleosis is primarily clinical, supported by laboratory tests that confirm the infection.

a) Monospot Test (Heterophile Antibody Test):

What it examines: Detects heterophile antibodies, which are typically produced in response to EBV infection.

Purpose: A rapid, widely used test that confirms the presence of infectious mononucleosis, although it may be negative in the early phase or in young children.

b) EBV-Specific Antibody Testing:

What it examines: Measures IgM and IgG antibodies against EBV viral capsid antigen (VCA) and early antigen (EA).

Purpose: Confirms acute EBV infection if the Monospot test is negative, or if there is diagnostic uncertainty. A positive **IgM VCA** indicates acute infection, while positive **IgG VCA** without IgM suggests past infection.

c) Full Blood Count (FBC):

What it measures: White blood cell (WBC) count, including lymphocyte count and the presence of atypical lymphocytes.

Purpose: Typically shows an elevated WBC count with a high proportion of atypical lymphocytes (greater than 10%).

d) Liver Function Tests (LFTs):

What it measures: Alanine transaminase (ALT), aspartate transaminase (AST), and bilirubin levels.

Purpose: Mild elevations in liver enzymes (ALT and AST) and, in some cases, bilirubin are common during the acute phase of infection.

e) Abdominal Ultrasound (if splenomegaly is suspected):

What it examines: The size of the spleen and liver.

Purpose: Confirms splenomegaly and assesses the risk of splenic rupture in symptomatic patients or athletes.

4. Explanation of Investigations

a) Monospot Test:

This test detects heterophile antibodies that are typically present in EBV infection. It is highly specific for infectious mononucleosis but may miss cases in the early stages of the disease or in young children. A positive result strongly supports the diagnosis.

b) EBV-Specific Antibody Testing:

This test measures antibodies specific to EBV antigens and is the gold standard for diagnosing EBV infection. IgM antibodies to viral capsid antigen (VCA) confirm acute infection, while the presence of IgG without IgM suggests a past infection.

5. Diagnostic Criteria for Infectious Mononucleosis

The diagnosis of infectious mononucleosis is based on a combination of clinical symptoms and laboratory findings:

Clinical Features: Fever, sore throat, and lymphadenopathy (especially posterior cervical lymph nodes), along with fatigue.

Monospot Test: A positive heterophile antibody test supports the diagnosis.

Atypical Lymphocytes: Greater than 10% atypical lymphocytes on a peripheral blood smear.

EBV Antibodies: Positive **EBV IgM VCA** antibodies confirm acute EBV infection.

According to **NICE guidelines**, the diagnosis can often be made clinically, especially if the patient has the classic symptoms, supported by blood tests.

6. First-Line Therapy According to Guidelines

There is no specific antiviral treatment for infectious mononucleosis, and management is mainly supportive, focusing on symptom relief.

a) Rest and Hydration:

Action: Encourage bed rest and increased fluid intake to help manage fatigue and systemic symptoms.

Outcome: Most patients recover fully with rest, though fatigue may persist for weeks.

b) Analgesics and Antipyretics:

Action: Use **paracetamol** or **ibuprofen** to relieve sore throat, headache, and fever.

Outcome: Provides symptomatic relief of fever, sore throat, and generalised discomfort.

c) Avoidance of Strenuous Activity:

Action: Patients should avoid contact sports or strenuous activity for at least 4-6 weeks, especially if splenomegaly is present, to reduce the risk of splenic rupture.

Outcome: Prevents complications such as splenic rupture, which can be life-threatening.

d) Corticosteroids (in severe cases):

Action: **Prednisolone** may be used in cases of significant airway obstruction due to tonsillar swelling or in patients with severe thrombocytopenia or haemolytic anaemia.

Dose: Prednisolone 40-60 mg daily for 3-5 days.

Outcome: Reduces inflammation and swelling, particularly in cases of airway obstruction or severe haematological complications.

e) Antibiotics (if bacterial superinfection suspected):

Action: In cases of secondary bacterial infections, such as streptococcal tonsillitis, appropriate antibiotics should be used. **Avoid amoxicillin or ampicillin**, as these can cause a rash in patients with EBV.

Outcome: Resolves bacterial superinfections and prevents complications.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Amoxicillin or Ampicillin: These antibiotics should not be used in patients with suspected infectious mononucleosis as they often cause a characteristic maculopapular rash in these patients.

b) Second-Line Therapy:

Antiviral Therapy:

Indication: Antivirals such as **acyclovir** are not routinely recommended for uncomplicated EBV infections but may be considered in severe, chronic, or immunocompromised patients with EBV-related complications.

Outcome: The use of antivirals is limited and generally does not alter the course of uncomplicated infectious mononucleosis.

Hospitalisation:

Indication: For patients with severe complications such as airway obstruction, severe dehydration, or splenic rupture, hospital admission may be required.

Outcome: Provides intensive monitoring and intervention in patients with life-threatening complications.

8. Routine Monitoring and Follow-Up

a) Symptom Monitoring:

Patients should be monitored for resolution of symptoms, particularly fatigue and sore throat. Fatigue may persist for weeks or months, and patients should be reassured about the expected course of recovery.

b) Splenomegaly Monitoring:

If splenomegaly is present, patients should avoid physical activity for at least 4-6 weeks and follow up with their physician to ensure the spleen returns to normal size.

c) Complications Monitoring:

Patients with persistent symptoms, jaundice, or signs of airway obstruction should be closely monitored. If symptoms worsen, further investigation and hospitalisation may be required.

9. Complications of Infectious Mononucleosis

a) Splenic Rupture:

A rare but life-threatening complication that can occur due to trauma or strenuous activity. It presents with acute abdominal pain, shock, and signs of internal bleeding.

b) Airway Obstruction:

Severe pharyngeal or tonsillar swelling can cause significant airway obstruction, necessitating corticosteroids or, in rare cases, intubation.

c) Autoimmune Complications:

Patients may develop autoimmune haemolytic anaemia, thrombocytopenia, or, rarely, Guillain-Barré syndrome.

d) Chronic Fatigue:

Some patients may experience prolonged fatigue lasting several months, which can impact their quality of life and daily functioning.

e) Secondary Infections:

Bacterial superinfections, such as streptococcal tonsillitis or pneumonia, can occur during the course of infectious mononucleosis.

Summary of Key Points for Infectious Mononucleosis

Infectious mononucleosis, caused by **EBV**, is characterised by fever, sore throat, lymphadenopathy, and fatigue, and is most common in adolescents and young adults.

Diagnosis is made with a **Monospot test** or **EBV-specific antibody testing**, along with supportive findings such as atypical lymphocytosis.

Treatment is primarily supportive, with rest, hydration, and **analgesics** for symptom relief. **Corticosteroids** may be used in severe cases.

Patients should avoid strenuous activity for 4-6 weeks due to the risk of **splenic rupture**, and follow-up is essential to monitor for complications and ensure full recovery.

156. Laryngitis

1. Detailed Definition of Laryngitis

Laryngitis is the inflammation of the larynx (voice box), which can be **acute** or **chronic**. It commonly results in hoarseness, loss of voice (aphonia), and throat discomfort. Laryngitis is usually caused by **viral infections**, but it can also result from **bacterial infections**, **vocal strain**, or **irritants** such as smoking or gastroesophageal reflux. Chronic laryngitis typically lasts for more than three weeks and may be caused by prolonged exposure to irritants, such as cigarette smoke or vocal overuse.

2. Common Presenting Complaints and Symptoms

Patients with laryngitis typically present with:

a) **Hoarseness or Voice Changes:**

The hallmark symptom of laryngitis is hoarseness, which may range from mild to complete voice loss (aphonia).

b) **Sore Throat or Throat Irritation:**

Discomfort or a scratchy sensation in the throat, often worsened by talking or swallowing.

c) **Dry Cough:**

A persistent, dry, non-productive cough is common and may be accompanied by throat clearing.

d) **Difficulty Speaking:**

Patients may experience fatigue or pain while speaking due to vocal strain.

e) **Low-Grade Fever:**

In cases of viral or bacterial laryngitis, a mild fever may occur.

f) **Tickling Sensation in the Throat:**

A frequent urge to clear the throat or cough.

g) **Swollen Lymph Nodes:**

Occasionally, patients may present with swollen cervical lymph nodes, especially if the laryngitis is part of a broader respiratory infection.

3. First-Line Investigations

The diagnosis of acute laryngitis is typically clinical and does not usually require extensive investigations unless symptoms persist or there are signs of complications.

a) **Laryngoscopy** (if indicated):

What it examines: Direct visualisation of the larynx using a flexible or rigid laryngoscope.

Purpose: Used to confirm inflammation of the vocal cords, identify any vocal cord lesions, or exclude serious causes like malignancy in chronic or persistent cases.

b) **Throat Swab (if bacterial infection suspected):**

What it examines: Identifies bacterial pathogens such as **Streptococcus pyogenes**.

Purpose: Used when there is suspicion of bacterial infection, though viral infections are more common in laryngitis.

c) **Complete Blood Count (CBC)** (if indicated):

What it measures: White blood cell (WBC) count.

Purpose: May show elevated WBCs in bacterial infections or a viral pattern with lymphocytosis, but this is rarely needed in routine cases.

d) **Chest X-ray** (in chronic or severe cases):

What it examines: The lungs and airway structures.

Purpose: Useful to rule out other causes of chronic hoarseness, such as lung pathology or mass effect on the recurrent laryngeal nerve, particularly in smokers.

e) **Voice Analysis** (if indicated in chronic cases):

What it examines: Evaluates vocal cord function and voice quality.

Purpose: Useful in cases of chronic laryngitis where vocal cord dysfunction is suspected.

4. Explanation of Investigations

a) **Laryngoscopy:**

This is the gold standard for visualising the vocal cords and diagnosing laryngitis. It shows inflamed, red, and swollen vocal cords, confirming the diagnosis. Laryngoscopy is particularly important in cases of chronic hoarseness to rule out other causes, such as vocal cord polyps, nodules, or cancer.

b) **Throat Swab:**

A throat swab is rarely necessary in routine cases of laryngitis, but it can be useful if there is suspicion of bacterial infection (e.g., streptococcal pharyngitis) or if the patient is immunocompromised.

5. Diagnostic Criteria for Laryngitis

The diagnosis of laryngitis is made based on:

Clinical Symptoms: Hoarseness, sore throat, and a dry cough are the primary symptoms.

Physical Examination: Redness and swelling of the laryngeal mucosa or vocal cords during laryngoscopy.

Exclusion of Serious Causes: If symptoms persist for more than three weeks or there are red flags (e.g., weight loss, haemoptysis), further evaluation with imaging or biopsy may be necessary to rule out malignancy or other conditions.

According to **NICE guidelines**, patients with hoarseness lasting more than three weeks should be referred for laryngoscopy to exclude more serious underlying causes, particularly in smokers or those with a history of vocal abuse.

6. First-Line Therapy According to Guidelines

The management of laryngitis is primarily supportive and aimed at reducing symptoms while the condition resolves on its own. Antibiotics are not typically required, except in cases of confirmed bacterial infection.

Acute Laryngitis:

a) Voice Rest:

Action: Avoid speaking or straining the voice to allow the vocal cords to heal.

Outcome: Reduces irritation and prevents further damage to the vocal cords.

b) Hydration:

Action: Encourage increased fluid intake and humidified air to keep the throat moist.

Outcome: Helps soothe the throat and reduce coughing.

c) Analgesics and Antipyretics:

Action: **Paracetamol** or **ibuprofen** can be used to relieve throat pain, fever, and general discomfort.

Outcome: Provides symptomatic relief.

d) Avoidance of Irritants:

Action: Avoid smoking, alcohol, and exposure to pollutants or allergens.

Outcome: Prevents further irritation and promotes faster recovery.

Chronic Laryngitis:

e) Treatment of Underlying Causes:

Action: Address factors contributing to chronic laryngitis, such as smoking cessation, managing gastroesophageal reflux disease (GERD) with **proton pump inhibitors** (PPIs), or treating allergies with antihistamines.

Outcome: Reduces inflammation of the vocal cords and improves symptoms.

f) Corticosteroids (in severe cases):

Action: Short courses of oral or inhaled corticosteroids may be used in severe cases of laryngitis to reduce inflammation of the vocal cords.

Outcome: Provides quicker symptom resolution, particularly in professional voice users, though this should be done cautiously to avoid overuse.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Antibiotics: Antibiotics are contraindicated in viral laryngitis, as they have no benefit and may contribute to antibiotic resistance.

Steroid Overuse: Prolonged or frequent use of corticosteroids should be avoided due to potential side effects, including voice strain and immune suppression.

b) Second-Line Therapy:

Speech Therapy:

Indication: For patients with chronic laryngitis or vocal cord dysfunction, speech therapy can be helpful in retraining vocal use and reducing strain.

Outcome: Helps restore normal voice function and prevent recurrence in patients with chronic voice issues.

Surgical Treatment (if indicated):

Indication: For patients with chronic laryngitis caused by vocal cord polyps, nodules, or other structural abnormalities, surgical removal may be necessary.

Outcome: Improves voice quality and resolves hoarseness in cases where conservative management fails.

8. Routine Monitoring and Follow-Up**a) Symptom Monitoring:**

Patients should be monitored for symptom resolution, particularly in cases of acute laryngitis. Most cases resolve within 1-2 weeks with conservative management.

b) Referral for Laryngoscopy:

Patients with symptoms lasting more than three weeks, or those with concerning features such as weight loss, haemoptysis, or a history of smoking, should be referred for laryngoscopy to rule out malignancy or other serious conditions.

c) Management of Chronic Conditions:

For patients with chronic laryngitis caused by GERD, smoking, or environmental factors, regular follow-up to monitor symptom control and adherence to lifestyle modifications or medication (e.g., PPIs) is essential.

9. Complications of Laryngitis**a) Vocal Cord Damage:**

Prolonged or severe laryngitis can lead to vocal cord nodules or polyps, resulting in chronic hoarseness or loss of voice. Professional voice users (e.g., singers, teachers) are particularly at risk.

b) Chronic Laryngitis:

Acute laryngitis that is not properly managed or persists due to ongoing irritants can become chronic, leading to long-term voice changes and discomfort.

c) Airway Compromise (rare):

In rare cases, severe inflammation of the vocal cords and larynx can lead to significant airway obstruction, requiring medical intervention.

d) Laryngeal Cancer:

Chronic laryngitis, particularly in smokers, increases the risk of developing laryngeal cancer. Persistent hoarseness should always be investigated in patients at risk.

Summary of Key Points for Laryngitis

Laryngitis is the inflammation of the larynx, commonly caused by viral infections, vocal strain, or irritants. It typically presents with hoarseness, throat discomfort, and a dry cough.

Diagnosis is clinical, but **laryngoscopy** is essential in cases of chronic or severe hoarseness to rule out more serious conditions.

First-line treatment includes **voice rest**, **hydration**, and **analgesics**. Antibiotics are generally not indicated unless a bacterial infection is confirmed.

Chronic cases require addressing underlying causes such as **smoking**, **GERD**, or **allergies**, with referral for further investigation if symptoms persist.

157. Ménière's Disease

1. Detailed Definition of Ménière's Disease

Ménière's disease is a chronic disorder of the inner ear characterized by recurrent episodes of **vertigo**, **sensorineural hearing loss**, **tinnitus**, and a sensation of **aural fullness**. It is thought to result from abnormal fluid (endolymph) accumulation in the inner ear's vestibular and cochlear structures (endolymphatic hydrops). This buildup distorts normal hearing and balance functions, causing the symptoms.

Ménière's disease typically affects one ear, though it can affect both ears in some cases. The condition is episodic, with periods of remission between episodes.

2. Common Presenting Complaints and Symptoms

Patients with Ménière's disease often present with the following symptoms, typically affecting one ear:

a) **Vertigo:**

Sudden, severe episodes of spinning sensation, which can last from 20 minutes to several hours. Episodes are often unpredictable and associated with nausea and vomiting.

b) **Hearing Loss:**

Initially fluctuating sensorineural hearing loss, usually affecting low frequencies in the early stages. Over time, hearing loss may become permanent.

c) **Tinnitus:**

Ringling, buzzing, or roaring sounds in the affected ear, which may fluctuate in intensity and are often worse during vertigo attacks.

d) **Aural Fullness:**

A sensation of pressure or fullness in the affected ear, often preceding or accompanying vertigo attacks.

e) **Imbalance or Unsteadiness:**

Patients may feel off-balance or unsteady even when not experiencing vertigo. This can persist between episodes.

3. First-Line Investigations

The diagnosis of Ménière's disease is primarily clinical, but several tests may be used to support the diagnosis and rule out other causes.

a) **Audiometry:**

What it examines: Measures hearing thresholds across different frequencies and assesses the type of hearing loss.

Purpose: Confirms sensorineural hearing loss, typically affecting low frequencies in early-stage Ménière's disease. Audiograms show fluctuating hearing loss, which may worsen over time.

b) **Electrocochleography (ECoG):**

What it examines: Measures electrical potentials generated in the inner ear in response to sound.

Purpose: Used to detect abnormal fluid pressure (endolymphatic hydrops) in the cochlea, supporting the diagnosis of Ménière's disease.

c) **Vestibular Testing (e.g., Videonystagmography, Caloric Testing):**

What it examines: Evaluates the function of the vestibular (balance) system.

Purpose: Identifies abnormal vestibular function, often reduced in the affected ear in patients with Ménière's disease.

d) **MRI of the Brain and Internal Auditory Canal:**

What it examines: Detailed imaging of the brain and inner ear structures.

Purpose: Rules out other causes of vertigo and hearing loss, such as vestibular schwannoma (acoustic neuroma), stroke, or multiple sclerosis.

4. Explanation of Investigations

a) **Audiometry:**

This is the cornerstone diagnostic test for Ménière's disease. It detects fluctuating sensorineural hearing loss, typically affecting the low frequencies in early stages, which may become more severe and affect higher frequencies as the disease progresses.

b) **Electrocochleography (ECoG):**

ECoG is used to detect endolymphatic hydrops by measuring abnormal electrical responses from the cochlea. It can help differentiate Ménière's disease from other vestibular disorders.

5. Diagnostic Criteria for Ménière's Disease

The diagnosis of Ménière's disease is based on a combination of clinical features and audiometric findings. The **American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS)** diagnostic criteria include:

Two or more spontaneous episodes of vertigo: Each lasting 20 minutes to 12 hours.

Audiometrically documented sensorineural hearing loss: In the affected ear at least once.

Tinnitus or aural fullness: In the affected ear.

Exclusion of other vestibular diagnoses: Through clinical examination and imaging.

According to **NICE guidelines**, the diagnosis should be confirmed by an audiogram showing sensorineural hearing loss and the typical episodic nature of symptoms.

6. First-Line Therapy According to Guidelines

The management of Ménière's disease focuses on controlling symptoms, reducing the frequency of attacks, and preserving hearing. Treatment includes lifestyle modifications, medications, and, in severe cases, surgical interventions.

a) Lifestyle Modifications:

Action: Advise patients to follow a **low-sodium diet**, avoid caffeine and alcohol, and reduce stress to help control fluid balance in the inner ear.

Outcome: May reduce the frequency and severity of vertigo attacks.

b) Vestibular Suppressants (e.g., Betahistine):

Action: Betahistine (16-48 mg/day in divided doses) improves blood flow in the inner ear, reducing endolymphatic pressure.

Outcome: May help reduce the frequency and severity of vertigo episodes.

c) Diuretics:

Action: Hydrochlorothiazide or other diuretics may be used to reduce fluid retention in the inner ear.

Outcome: Reduces the frequency of vertigo attacks by managing endolymphatic hydrops.

d) Antiemetics (for acute episodes):

Action: Medications such as **prochlorperazine** or **promethazine** can help control nausea and vomiting during acute vertigo episodes.

Outcome: Provides symptomatic relief during vertigo attacks.

e) Corticosteroids (intra-tympanic injection in resistant cases):

Action: Injections of corticosteroids into the middle ear can reduce inflammation and pressure in the inner ear.

Outcome: Can reduce vertigo episodes and preserve hearing in patients with more severe disease.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Diuretics: Use with caution in patients with renal impairment or electrolyte imbalances.

Betahistine: Should be used cautiously in patients with a history of peptic ulcers or asthma.

b) Second-Line Therapy:

Intra-Tympanic Gentamicin (for refractory cases):

Indication: For patients who do not respond to conservative measures or medical therapy.

Action: Gentamicin ablates the vestibular function in the affected ear, reducing vertigo episodes by destroying the sensory cells responsible for balance.

Outcome: Very effective in controlling vertigo but may result in permanent hearing loss in the treated ear.

Endolymphatic Sac Decompression:

Indication: For patients with persistent vertigo who do not respond to medical treatment.

Action: Surgical decompression of the endolymphatic sac to reduce fluid pressure.

Outcome: Reduces the frequency of vertigo episodes, with a low risk of hearing loss.

Labyrinthectomy or Vestibular Nerve Section:

Indication: For severe, refractory Ménière's disease.

Action: Surgical removal of the inner ear (labyrinthectomy) or cutting the vestibular nerve (vestibular nerve section) to control vertigo.

Outcome: Controls vertigo completely but results in permanent hearing loss in the affected ear.

8. Routine Monitoring and Follow-Up

a) Hearing Monitoring:

Patients with Ménière's disease should have regular audiometry to monitor the progression of hearing loss.

b) Symptom Monitoring:

Patients should be followed up regularly to assess the frequency and severity of vertigo attacks and adjust medications or treatment as needed.

c) Vestibular Rehabilitation:

Patients who develop chronic imbalance or unsteadiness between vertigo attacks may benefit from vestibular rehabilitation exercises to improve balance and reduce fall risk.

9. Complications of Ménière's Disease

a) **Progressive Hearing Loss:**

Over time, patients with Ménière's disease may experience permanent hearing loss in the affected ear, which can worsen with recurrent attacks.

b) **Falls and Injuries:**

Vertigo attacks and imbalance increase the risk of falls and associated injuries, particularly in older adults.

c) **Psychosocial Impact:**

The unpredictability of vertigo attacks and the progressive nature of hearing loss can lead to anxiety, depression, and social isolation.

d) **Bilateral Ménière's Disease:**

In some cases, the disease may affect both ears, leading to more severe hearing impairment and balance issues.

Summary of Key Points for Ménière's Disease

Ménière's disease is characterized by recurrent episodes of vertigo, sensorineural hearing loss, tinnitus, and aural fullness, often due to abnormal fluid buildup in the inner ear.

Diagnosis is based on clinical criteria, supported by **audiometry**, **vestibular testing**, and **MRI** to rule out other causes.

First-line treatment includes **lifestyle modifications**, **betahistidine**, and **diuretics**, with intra-tympanic injections and surgery reserved for refractory cases.

Regular monitoring of **hearing** and **balance** is crucial to manage the progression of the disease and to provide appropriate treatment for symptomatic relief.

158. Nasal Trauma

1. Detailed Definition of Nasal Trauma

Nasal trauma refers to any injury to the nose, which may involve the bony and cartilaginous structures of the nasal framework as well as the overlying soft tissues. It is one of the most common facial injuries and can result from blunt force (e.g., from a fall, sports injury, or assault), penetrating trauma, or fractures. Nasal trauma can lead to **nasal fractures**, **septal haematoma**, **deviation**, or soft tissue injuries, and may affect both the aesthetics and function of the nose.

2. Common Presenting Complaints and Symptoms

Patients with nasal trauma typically present with:

a) **Nasal Pain and Tenderness:**

Pain, especially over the nasal bridge or dorsum, following trauma.

b) **Epistaxis (Nosebleed):**

Bleeding from the nose is common, either immediately after the injury or in the days following.

c) Swelling and Bruising:

Swelling of the nasal area, often accompanied by bruising around the eyes ("raccoon eyes"), which can indicate a nasal fracture.

d) Nasal Deformity:

Visible changes in the shape or alignment of the nose, such as a crooked or deviated appearance.

e) Nasal Obstruction:

Difficulty breathing through the nose due to internal swelling, septal deviation, or haematoma.

f) Crepitus:

A crackling sensation when touching the nose, indicating possible fracture of the nasal bones.

g) Septal Haematoma:

Swelling inside the nose, which may block one or both nostrils, caused by blood accumulating between the nasal septum and its overlying mucosa.

h) Loss of Smell (Anosmia):

Temporary or permanent reduction in the sense of smell due to damage to the nasal structures.

3. First-Line Investigations

The diagnosis of nasal trauma is primarily clinical, with the need for imaging depending on the severity of the injury and the presence of complications.

a) Physical Examination:

What it examines: Visual and manual inspection of the nose for deformities, swelling, septal haematoma, and nasal obstruction.

Purpose: To identify fractures, displacements, or haematomas that may require further management.

b) Nasal Endoscopy:

What it examines: A detailed examination of the nasal cavity using a flexible or rigid endoscope.

Purpose: Confirms the presence of septal haematoma, mucosal injuries, or other internal nasal damage that is not visible on the external examination.

c) X-ray of the Nasal Bones:

What it examines: The bony structures of the nose.

Purpose: Although not routinely required for nasal fractures, X-rays may be useful in cases of severe trauma or when there is significant deformity or suspicion of multiple fractures.

d) **CT Scan of the Facial Bones:**

What it examines: Detailed imaging of the nasal bones and surrounding structures.

Purpose: Used for complex fractures, suspected facial fractures extending beyond the nose, or if there is suspicion of intracranial injury.

e) **Assessment for Other Facial Injuries:**

What it examines: A full assessment of the facial bones, teeth, and skull.

Purpose: Ensures that associated injuries, such as orbital or maxillary fractures, are not missed.

4. Explanation of Investigations

a) **Physical Examination:**

A thorough physical exam is the most important initial investigation. Palpation of the nasal bones and septum helps identify fractures, and visual inspection of the nasal passages helps detect septal haematomas or other internal injuries. A septal haematoma is a surgical emergency as it can lead to necrosis of the septal cartilage.

b) **CT Scan:**

CT scans are more sensitive than X-rays for identifying fractures, especially those that involve the nasal bones, septum, and orbit. A CT scan is indicated in severe trauma cases or when there is suspicion of associated facial fractures.

5. Diagnostic Criteria for Nasal Trauma

The diagnosis of nasal trauma is based on:

History of Trauma: Direct impact to the nose with associated pain, swelling, bleeding, or deformity.

Physical Examination Findings: Visible deformity, crepitus, septal haematoma, and nasal obstruction.

Imaging (if indicated): X-ray or CT confirming fractures of the nasal bones, septum, or surrounding structures.

According to **NICE guidelines**, nasal fractures are typically diagnosed clinically without the need for routine imaging unless there is suspicion of severe or complex injury.

6. First-Line Therapy According to Guidelines

Management of nasal trauma is based on the severity of the injury and any complications, such as fractures or septal haematoma. Treatment focuses on controlling symptoms and preventing long-term functional or cosmetic issues.

a) **Analgesics and Anti-Inflammatory Medications:**

Action: Paracetamol or ibuprofen can be used to control pain and reduce inflammation.

Outcome: Provides relief from pain and reduces swelling after nasal trauma.

b) Cold Compresses:

Action: Apply ice packs to the nose to reduce swelling and control bruising.

Outcome: Minimises swelling and pain in the initial hours after injury.

c) Reduction of Nasal Fracture (if needed):

Action: Closed reduction of the nasal bones should be performed within 7-14 days after the injury to restore the nasal shape if there is significant displacement.

Outcome: Realigns the nasal bones, improving both function and aesthetics. Early intervention reduces the risk of permanent nasal deformity.

d) Drainage of Septal Haematoma:

Action: Septal haematomas require urgent drainage to prevent cartilage necrosis, which can lead to septal perforation or saddle nose deformity.

Outcome: Prevents serious complications by removing the blood clot and allowing the septum to heal properly.

e) Antibiotics (if there is an open fracture or septal haematoma):

Action: Prophylactic antibiotics, such as **amoxicillin-clavulanate**, may be given to prevent infection in cases of open fractures or after drainage of a septal haematoma.

Outcome: Reduces the risk of infection, especially in cases where the mucosa is breached.

f) Nasal Packing (if severe epistaxis):

Action: Nasal packing with gauze or nasal tampons may be needed to control significant nasal bleeding.

Outcome: Temporarily stops epistaxis while the nasal injury heals.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Delay in Treating Septal Haematoma: Failure to treat a septal haematoma promptly can lead to irreversible septal damage and deformity.

b) Second-Line Therapy:

Rhinoplasty (for cosmetic deformity):

Indication: If the nose remains deformed after the initial injury or reduction, rhinoplasty may be required to correct cosmetic issues.

Outcome: Restores the normal shape and appearance of the nose.

Functional Nasal Surgery (if obstruction persists):

Indication: For patients with persistent nasal obstruction due to septal deviation or scarring, septoplasty or turbinate reduction may be needed.

Outcome: Improves nasal airflow and restores normal breathing function.

8. Routine Monitoring and Follow-Up

a) Follow-Up for Fracture Reduction:

Patients who undergo reduction of nasal fractures should be followed up within 7-14 days to assess healing and ensure the nasal bones remain in alignment.

b) Monitoring for Complications:

Patients with septal haematomas, nasal fractures, or significant soft tissue injuries should be monitored for signs of infection, persistent nasal obstruction, or cosmetic deformity.

c) Referral for Rhinoplasty or Functional Surgery:

If the patient develops long-term issues with nasal breathing or deformity, referral to an ENT surgeon or plastic surgeon for further corrective procedures may be necessary.

9. Complications of Nasal Trauma

a) Septal Haematoma:

Undiagnosed or untreated septal haematomas can lead to necrosis of the septal cartilage, resulting in a saddle nose deformity or septal perforation.

b) Nasal Deformity:

Untreated or improperly treated nasal fractures can result in permanent cosmetic deformities, such as a crooked or deviated nose.

c) Chronic Nasal Obstruction:

Septal deviations or scarring from the injury can lead to long-term difficulty breathing through the nose, requiring surgical intervention.

d) Infection:

Open fractures or septal haematomas can become infected, leading to abscess formation or systemic infection.

e) Anosmia:

Trauma to the nasal structures can affect the olfactory nerves, leading to partial or complete loss of smell, which may be temporary or permanent.

Summary of Key Points for Nasal Trauma

Nasal trauma can involve fractures, septal haematomas, and soft tissue injuries, leading to pain, swelling, nasal obstruction, and deformity.

Diagnosis is primarily clinical, with imaging reserved for complex fractures or suspected associated injuries.

First-line treatment includes **analgesics**, **cold compresses**, **fracture reduction**, and **septal haematoma drainage**. Early intervention can prevent long-term complications.

Complications include **nasal deformity**, **septal necrosis**, and **chronic obstruction**, which may require surgical correction.

159. Otitis Externa

1. Detailed Definition of Otitis Externa

Otitis externa (OE), also known as **swimmer's ear**, is an inflammation or infection of the external auditory canal, the auricle, or both. It is commonly caused by **bacterial infection** (e.g., *Pseudomonas aeruginosa* and *Staphylococcus aureus*), but it can also be due to fungal infections, allergies, or irritants such as water or foreign objects in the ear canal. OE can be classified into **acute** (lasting less than 3 weeks) or **chronic** (lasting more than 3 months).

Acute otitis externa is often related to excessive moisture in the ear canal or trauma to the skin of the ear canal, disrupting the natural protective barrier and allowing pathogens to invade.

2. Common Presenting Complaints and Symptoms

Patients with otitis externa often present with:

a) **Ear Pain (Otalgia):**

The primary symptom, ranging from mild discomfort to severe pain, often worsened by touching or moving the outer ear or jaw.

b) **Itching (Pruritus):**

Itching in the ear canal is common, especially in the early stages or with fungal infections.

c) **Ear Discharge (Otorrhoea):**

A discharge of clear, yellow, or green fluid may be seen, especially in bacterial infections. Fungal infections may produce a fluffy white or black discharge.

d) **Hearing Loss:**

Conductive hearing loss can occur if the ear canal becomes blocked by swelling or debris.

e) **Swelling and Redness:**

Swelling of the ear canal and redness of the outer ear are commonly noted during examination.

f) **Tenderness of the External Ear:**

Pain is typically exacerbated by pulling on the pinna or pushing on the tragus.

g) **Fullness or Pressure Sensation:**

Patients may feel a sense of fullness or pressure in the affected ear due to inflammation or blockage of the ear canal.

3. First-Line Investigations

The diagnosis of otitis externa is primarily clinical and based on history and physical examination. In most cases, additional investigations are not required unless the patient has recurrent infections or treatment resistance.

a) **Otoscopy:**

What it examines: Visual inspection of the external auditory canal and tympanic membrane.

Purpose: Confirms inflammation of the ear canal, assesses for discharge, erythema, and swelling, and ensures the tympanic membrane is intact.

b) **Ear Swab (for culture):**

What it examines: Microbiological culture of ear discharge or debris.

Purpose: Useful if initial treatment fails or if fungal infection or resistant bacteria are suspected. It helps guide appropriate antibiotic or antifungal therapy.

c) **Audiometry (if hearing loss persists):**

What it examines: Assesses the level of hearing loss.

Purpose: Conductive hearing loss in otitis externa is usually transient, but audiometry can rule out other causes if hearing loss persists after infection resolution.

4. Explanation of Investigations

a) **Otoscopy:**

This is the main diagnostic tool for otitis externa. It reveals inflammation, swelling, and redness of the ear canal, with or without discharge. The tympanic membrane should be inspected to rule out middle ear infection or perforation, which may require different management.

b) **Ear Swab:**

In cases of treatment failure or suspicion of fungal otitis externa, an ear swab is taken for culture and sensitivity. This can identify the causative organism and guide the selection of appropriate antimicrobial treatment, especially in resistant infections.

5. Diagnostic Criteria for Otitis Externa

The diagnosis of otitis externa is based on:

History: Pain, itching, and discharge from the ear, often worsened by moisture exposure (e.g., swimming).

Physical Examination: Swollen, red ear canal with tenderness on palpation of the tragus or pinna.

Otoscopy: Confirms inflammation or infection of the ear canal, with or without debris or discharge.

6. First-Line Therapy According to Guidelines

The treatment of otitis externa involves controlling infection, reducing inflammation, and promoting healing of the ear canal. The primary treatment is topical therapy, as systemic antibiotics are rarely needed.

a) Topical Antibiotics with or without Steroids:

Action: Topical antibiotic drops (e.g., **ciprofloxacin** or **neomycin**) with or without corticosteroids (e.g., **hydrocortisone** or **dexamethasone**) reduce bacterial load and inflammation.

Outcome: Effective in clearing bacterial infections and reducing pain and swelling. Steroids help decrease inflammation and itching.

b) Ear Cleaning (Aural Toilet):

Action: Cleaning the ear canal to remove debris, discharge, and infected material.

Outcome: Improves the effectiveness of topical treatments and reduces irritation and blockage in the canal.

c) Topical Antifungals (if fungal infection is suspected):

Action: **Clotrimazole** or **acetic acid** drops can be used to treat fungal otitis externa.

Outcome: Effective in clearing fungal infections, particularly after a course of antibiotics or in recurrent infections.

d) Pain Management:

Action: **Paracetamol** or **ibuprofen** to manage pain and inflammation.

Outcome: Provides symptomatic relief, especially in cases of severe otalgia.

e) Keep the Ear Dry:

Action: Instruct the patient to avoid getting water into the ear by using earplugs during bathing or swimming.

Outcome: Prevents further irritation and recurrence by keeping the ear canal dry.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Ototoxic Topical Agents: Avoid **aminoglycoside** ear drops (e.g., neomycin) in patients with a perforated tympanic membrane due to the risk of ototoxicity.

b) Second-Line Therapy:

Oral Antibiotics (if severe or spreading infection):

Indication: For severe cases of otitis externa with cellulitis or spreading infection beyond the ear canal.

Action: Systemic antibiotics such as **flucloxacillin** or **ciprofloxacin** may be prescribed if the infection spreads to surrounding tissues.

Outcome: Controls the spread of the infection and prevents complications such as perichondritis or mastoiditis.

Microsuction:

Indication: For patients with persistent debris, chronic otitis externa, or if irrigation is contraindicated.

Action: A specialist ENT procedure to clean the ear canal under direct vision using suction.

Outcome: Clears the canal, improving symptom relief and the effectiveness of topical treatments.

8. Routine Monitoring and Follow-Up

a) Symptom Monitoring:

Patients should be monitored for resolution of pain, discharge, and hearing loss. Follow-up may be needed if symptoms persist beyond the expected recovery period (7-10 days).

b) Re-evaluation for Recurrent Infections:

In patients with recurrent otitis externa, further investigation may be necessary to identify underlying conditions (e.g., eczema, fungal infections, or chronic exposure to water). Patients may require long-term management, including regular ear cleaning and use of preventative drops (e.g., acetic acid drops).

9. Complications of Otitis Externa

a) Chronic Otitis Externa:

Recurrent or persistent otitis externa can become chronic, leading to thickening of the ear canal, chronic discharge, and persistent itching.

b) Malignant Otitis Externa:

A rare but serious complication, particularly in immunocompromised patients (e.g., those with diabetes). It involves the spread of infection to the bones of the skull (osteomyelitis) and can be life-threatening without prompt treatment.

c) Hearing Loss:

Temporary conductive hearing loss may occur due to blockage of the ear canal by swelling or debris. Permanent hearing loss is rare but can occur if the infection spreads to deeper structures.

d) Perichondritis:

Infection of the cartilage of the ear can occur as a complication of severe otitis externa, leading to ear deformity if not treated.

Summary of Key Points for Otitis Externa

Otitis externa is an inflammation or infection of the external ear canal, most commonly caused by bacteria or fungi.

Diagnosis is clinical, with **otoscopy** used to confirm inflammation and rule out middle ear involvement.

First-line treatment includes **topical antibiotics** with or without steroids, ear cleaning, and **pain management**.

Preventative measures, such as keeping the ear dry, are essential to avoid recurrence.

Complications include **chronic otitis externa**, **malignant otitis externa**, and **hearing loss**, which may require more aggressive treatment or referral to ENT specialists.

160. Otitis Media

1. Detailed Definition of Otitis Media

Otitis media refers to inflammation or infection of the middle ear, typically occurring behind the tympanic membrane. It can be classified into **acute otitis media (AOM)**, **otitis media with effusion (OME)** (also known as **glue ear**), and **chronic suppurative otitis media (CSOM)**. AOM is usually caused by a bacterial or viral infection, often following an upper respiratory tract infection (URTI). OME involves fluid accumulation in the middle ear without infection, and CSOM involves chronic infection of the middle ear with perforation of the tympanic membrane and persistent ear discharge.

2. Common Presenting Complaints and Symptoms

Acute Otitis Media (AOM): a) Ear Pain (Otalgia):

Sudden onset of moderate to severe ear pain, often worsened by lying down.

b) Fever:

Common, particularly in children, with temperatures often exceeding 38°C.

c) Hearing Loss:

Conductive hearing loss in the affected ear due to fluid or pus accumulation in the middle ear.

d) Ear Discharge (Otorrhoea):

If the tympanic membrane perforates, there may be a purulent or serous discharge from the ear.

e) Irritability and Feeding Difficulties (in children):

Young children may present with irritability, difficulty feeding, or tugging at their ears.

f) Vertigo or Dizziness:

Less common but can occur if the infection spreads to the inner ear.

Otitis Media with Effusion (OME):

Hearing Loss: A primary symptom, as fluid in the middle ear impairs sound conduction.

Fullness or Pressure in the Ear: A feeling of fullness or popping sensation in the ear.

No Significant Pain or Fever: OME typically lacks the acute inflammatory symptoms of AOM.

Chronic Suppurative Otitis Media (CSOM):

Persistent Ear Discharge: Ongoing or recurrent purulent discharge through a perforated tympanic membrane.

Hearing Loss: Conductive hearing loss due to chronic damage or perforation of the tympanic membrane.

No Significant Pain: Pain is usually absent unless there is acute exacerbation.

3. First-Line Investigations

Acute Otitis Media (AOM) is primarily a clinical diagnosis, based on history and otoscopic examination.

a) Otoscopy:

What it examines: Visual inspection of the tympanic membrane.

Purpose: In AOM, the tympanic membrane may appear red, bulging, and immobile, with possible fluid or pus visible behind it. In OME, the tympanic membrane appears retracted or has fluid behind it without signs of acute infection.

b) Tympanometry (for OME):

What it examines: Measures the movement of the tympanic membrane in response to air pressure changes.

Purpose: Confirms the presence of fluid in the middle ear (OME) by showing reduced mobility of the tympanic membrane.

c) Audiometry (for OME or CSOM):

What it examines: Assesses hearing thresholds.

Purpose: Identifies conductive hearing loss due to fluid in the middle ear or perforation of the tympanic membrane.

d) Ear Swab (for culture, in CSOM):

What it examines: Identifies bacterial organisms in persistent ear discharge.

Purpose: Guides appropriate antibiotic therapy in chronic or refractory infections.

e) CT Scan (in complicated cases):

What it examines: The middle and inner ear structures.

Purpose: Used to assess complications, such as mastoiditis or intracranial extension, in severe or chronic cases of otitis media.

4. Explanation of Investigations

a) **Otoscopy:**

This is the most important diagnostic tool in otitis media. In AOM, the tympanic membrane is red, bulging, and immobile, indicating infection and pus behind the eardrum. In OME, the membrane may appear dull or retracted, with visible fluid behind it. In CSOM, there may be perforation with active discharge.

b) **Tympanometry:**

Tympanometry measures the compliance of the tympanic membrane and middle ear pressure. A flat tympanogram (type B) suggests the presence of fluid in the middle ear, confirming otitis media with effusion.

5. Diagnostic Criteria for Otitis Media

The diagnosis of otitis media is based on:

History of Acute Symptoms: Sudden onset of ear pain, fever, and hearing loss in AOM; persistent ear discharge in CSOM; and hearing loss with no significant pain in OME.

Otoscopy Findings: Bulging, red tympanic membrane in AOM; fluid or retracted membrane in OME; perforation and discharge in CSOM.

Tympanometry or Audiometry: Used to confirm fluid in the middle ear or assess hearing loss in OME or CSOM.

According to **NICE guidelines**, most cases of AOM are diagnosed clinically without the need for additional tests.

6. First-Line Therapy According to Guidelines

Treatment of otitis media varies depending on the type and severity of the condition.

Acute Otitis Media (AOM):

a) **Analgesics (first-line treatment):**

Action: **Paracetamol** or **ibuprofen** to relieve pain and reduce fever.

Outcome: Provides symptomatic relief while the infection resolves, which happens in most cases without antibiotics.

b) **Antibiotics (in specific cases):**

Action: **Amoxicillin** is the first-line antibiotic for AOM if treatment is indicated.

Dose: Amoxicillin 500 mg three times daily for 5-7 days (or 40-90 mg/kg/day in children).

Outcome: Antibiotics are prescribed if symptoms persist beyond 48-72 hours, in children under 2 years with bilateral AOM, or in patients with perforation, severe illness, or immune compromise.

c) **Observation Without Antibiotics:**

Action: In many cases, particularly in children over 2 years with mild symptoms, observation for 48-72 hours without antibiotics is recommended.

Outcome: Many cases of AOM resolve spontaneously, and this approach helps avoid unnecessary antibiotic use.

Otitis Media with Effusion (OME):

d) **Watchful Waiting:**

Action: OME often resolves on its own, so initial management involves monitoring for 3 months before considering interventions.

Outcome: Most cases resolve spontaneously, particularly following an upper respiratory infection.

e) **Hearing Aids or Grommets** (if persistent OME with hearing loss):

Action: Surgical insertion of **grommets** (ventilation tubes) may be needed in children with persistent hearing loss or speech delays due to OME.

Outcome: Improves middle ear ventilation, resolves fluid buildup, and restores normal hearing.

Chronic Suppurative Otitis Media (CSOM):

f) **Topical Antibiotics (with or without steroids):**

Action: **Ciprofloxacin** ear drops to treat chronic infection and reduce inflammation.

Outcome: Controls the infection and reduces ear discharge.

g) **Ear Cleaning (Aural Toilet):**

Action: Cleaning of the ear canal to remove debris and discharge.

Outcome: Improves the effectiveness of topical treatments.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Topical Ototoxic Agents: Avoid **aminoglycoside**-based ear drops (e.g., neomycin) in patients with a perforated tympanic membrane, as these are ototoxic and can damage hearing.

b) **Second-Line Therapy:**

Surgical Myringotomy (for recurrent or severe AOM):

Indication: For patients with recurrent AOM or severe symptoms that do not respond to medical management.

Outcome: Relieves pressure in the middle ear by creating a small incision in the tympanic membrane to drain fluid or pus.

Mastoidectomy (for complicated CSOM):

Indication: For patients with CSOM and complications such as mastoiditis or cholesteatoma.

Outcome: Removes infected mastoid air cells to prevent further infection and complications.

8. Routine Monitoring and Follow-Up

a) Hearing Monitoring (for OME):

Patients with OME should be monitored for persistent hearing loss, especially in children, where this can affect speech and language development.

b) Follow-Up for Perforation (CSOM):

Patients with tympanic membrane perforation should be followed up to assess healing, as long-term perforations may require surgical repair (tympanoplasty).

c) Recurrence Prevention:

Patients with recurrent AOM may benefit from strategies to reduce risk factors, such as pneumococcal vaccination, reducing exposure to second-hand smoke, and addressing allergic rhinitis.

9. Complications of Otitis Media

a) Tympanic Membrane Perforation:

Acute infections or chronic inflammation can cause the tympanic membrane to rupture, leading to hearing loss

b) Chronic Suppurative Otitis Media (CSOM):

Persistent infection can lead to chronic discharge and conductive hearing loss.

c) Mastoiditis:

Infection can spread to the mastoid air cells, leading to severe pain, swelling behind the ear, and potential complications such as intracranial infections.

d) Hearing Loss:

Both AOM and OME can lead to temporary or permanent conductive hearing loss, particularly in children, which may affect language development.

e) Intracranial Complications:

In severe cases, infections may extend to the meninges (meningitis) or brain abscesses, which are serious and require urgent medical intervention.

f) Cholesteatoma:

This can develop in the context of recurrent AOM or CSOM, leading to erosion of surrounding structures and potential complications.

Summary of Key Points for Otitis Media

Otitis media includes AOM, OME, and CSOM, with AOM being the most common form.

AOM is characterized by sudden ear pain, fever, and possible discharge, whereas **OME** presents with hearing loss and a sensation of fullness without pain.

Diagnosis is primarily clinical, supported by otoscopy and tympanometry, with **NICE guidelines** recommending watchful waiting in mild cases of AOM.

First-line treatment involves analgesics and, in some cases, antibiotics (amoxicillin).

OME management includes observation, hearing assessments, and potential grommet insertion if persistent.

Routine monitoring is crucial for assessing hearing in children and managing any complications.

Complications can range from tympanic membrane perforation to more severe infections requiring surgical intervention.

161. Pinna Hematoma

1. Detailed Definition of Pinna Hematoma

A **pinna hematoma** is a localized collection of blood within the tissues of the external ear (pinna), typically resulting from trauma. It involves the accumulation of blood between the cartilage and the perichondrium (the connective tissue surrounding the cartilage) of the ear. This condition is commonly associated with **auricular hematoma** or **cauliflower ear**, particularly in individuals engaged in contact sports like wrestling, boxing, or rugby.

If not promptly and properly treated, a pinna hematoma can lead to cartilage necrosis, deformity of the ear (such as the characteristic "cauliflower" appearance), and long-term cosmetic and functional deficits.

2. Common Presenting Complaints and Symptoms

Patients with a pinna hematoma typically present with:

a) **Pain and Tenderness:**

Acute onset of ear pain following trauma.

The affected ear is tender to touch.

b) **Swelling and Edema:**

Noticeable swelling of the external ear, particularly over the cartilage.

The swelling may appear as a firm, fluctuant mass beneath the perichondrium.

c) **Discoloration:**

Bruising or discoloration (redness to purple) of the pinna due to blood accumulation.

d) **Deformity:**

In severe or untreated cases, the ear may develop a lumpy or deformed appearance.

e) Restricted Movement:

Limited mobility of the ear due to swelling and pain.

f) Warmth and Inflammation:

The affected area may feel warm to the touch and show signs of inflammation.

3. First-Line Investigations

Diagnosis of a pinna hematoma is primarily clinical, based on history and physical examination. However, in certain cases, additional investigations may be necessary.

a) Physical Examination:

What it examines: Inspection and palpation of the external ear.

Purpose: Identifies the presence of a hematoma, assesses the extent of swelling, and evaluates for any associated injuries such as lacerations or fractures.

b) Otoscopic Examination:

What it examines: Internal structures of the ear canal and tympanic membrane.

Purpose: Rules out concurrent middle ear injuries or hemotympanum (blood behind the tympanic membrane).

c) Imaging (if complicated trauma is suspected):

What it examines: Detailed visualization of the ear structures.

Purpose: Utilized in cases of severe trauma to rule out cartilage fractures or other complex injuries, though rarely required for isolated pinna hematoma.

4. Explanation of Investigations

a) Physical Examination:

The clinician inspects the external ear for signs of trauma, swelling, and discoloration. Palpation helps determine the presence and extent of the hematoma. A fluctuating, tense swelling beneath the perichondrium is indicative of a hematoma.

b) Otoscopic Examination:

This examination ensures that there are no internal ear injuries. It is essential to rule out other potential complications that might require different management strategies.

c) Imaging:

Generally not necessary for straightforward cases. Reserved for scenarios where there is suspicion of more extensive injury, such as fractures of the ear cartilage or surrounding facial bones.

5. Diagnostic Criteria for Pinna Hematoma

The diagnosis of pinna hematoma is based on:

History of Trauma: Recent direct injury to the ear, often associated with contact sports or accidents.

Clinical Signs: Presence of localized swelling, pain, tenderness, and discoloration of the external ear.

Palpation Findings: A tense, fluctuant mass beneath the perichondrium confirms the presence of a hematoma.

Absence of Other Injuries: Ensuring no concurrent middle or inner ear trauma that might alter management.

According to **NICE guidelines**, prompt recognition and management of pinna hematoma are crucial to prevent complications such as cartilage necrosis and permanent ear deformity.

6. First-Line Therapy According to Guidelines

The primary goal in managing a pinna hematoma is to evacuate the accumulated blood and prevent re-accumulation. Early intervention significantly reduces the risk of cartilage damage and resultant deformity.

a) Incision and Drainage:

Action: A small incision is made in the most tense area of the hematoma to drain the collected blood.

Outcome: Relieves pressure, reduces pain, and prevents cartilage necrosis.

b) Compression and Splinting:

Action: After drainage, the ear is compressed and a splint or packing material is applied to maintain the correct position of the cartilage and prevent re-accumulation of blood.

Outcome: Ensures the perichondrium stays adherent to the cartilage, promoting proper healing and maintaining ear shape.

c) Topical or Systemic Antibiotics:

Action: Prophylactic antibiotics may be prescribed to prevent secondary bacterial infection, especially if there are associated lacerations or in immunocompromised patients.

Outcome: Reduces the risk of infection, promoting faster and complication-free healing.

d) Pain Management:

Action: Use of analgesics such as **paracetamol** or **ibuprofen** to manage pain and inflammation.

Outcome: Provides symptomatic relief, improving patient comfort during recovery.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Incomplete Drainage: Avoid leaving residual hematoma after incision and drainage to prevent re-accumulation.

Uncontrolled Bleeding Disorders: Cautious approach or specialist referral is needed if the patient has coagulopathies.

Presence of Necrotic Tissue: Requires more extensive surgical intervention to remove dead cartilage and prevent spread of infection.

b) Second-Line Therapy:

Repeated Evacuation:

Indication: If the hematoma re-accumulates despite initial drainage and compression.

Outcome: Ensures complete evacuation and reduces the risk of recurrence and complications.

Surgical Intervention:

Indication: For extensive hematomas or those not responding to conservative management, surgical exploration and debridement may be necessary.

Outcome: Removes all affected tissue, prevents further complications, and restores ear anatomy.

Use of Foley Catheter or Needles for Drainage:

Indication: In cases where standard drainage techniques are insufficient.

Outcome: Facilitates continuous drainage and prevents re-accumulation of blood.

8. Routine Monitoring and Follow-Up

a) Follow-Up Appointments:

Action: Schedule follow-up visits within 24-48 hours after initial treatment to ensure the hematoma has not re-accumulated and that the ear is healing properly.

Outcome: Early detection of any recurrence or complications allows for timely intervention.

b) Monitoring for Infection:

Action: Observe for signs of infection such as increased redness, swelling, warmth, or purulent discharge.

Outcome: Promptly addressing infections prevents further tissue damage and systemic complications.

c) Assessment of Ear Shape and Function:

Action: Evaluate the cosmetic appearance of the ear and assess for any functional deficits, such as hearing loss or restricted movement.

Outcome: Ensures that the ear maintains its normal structure and function, and that any residual deformity is addressed early.

d) Patient Education:

Action: Advise patients on how to care for the treated ear, signs of complications to watch for, and when to seek further medical attention.

Outcome: Empowers patients to participate in their own care and ensures early recognition of any issues.

9. Complications of Pinna Hematoma

a) Cartilage Necrosis:

Description: Death of cartilage tissue due to prolonged pressure from the hematoma.

Consequence: Leads to permanent deformity of the ear, such as the "cauliflower ear" appearance.

b) Chondritis:

Description: Infection of the cartilage following hematoma formation.

Consequence: Can cause further cartilage damage and increased risk of necrosis.

c) Perichondritis:

Description: Infection of the perichondrium, the connective tissue surrounding the cartilage.

Consequence: May result in abscess formation and requires prompt antibiotic therapy.

d) Recurrent Hematoma Formation:

Description: Re-accumulation of blood after initial drainage and compression.

Consequence: Increases the risk of complications and may require repeated interventions.

e) Deformity of the Pinna:

Description: Permanent changes in the shape of the external ear due to unresolved hematoma or necrosis.

Consequence: Aesthetic concerns and potential psychosocial impact on the patient.

f) Hearing Loss:

Description: Rare, but swelling and structural changes can occasionally affect hearing.

Consequence: May require further evaluation and management if persistent.

Summary of Key Points for Pinna Hematoma

Pinna hematoma is a collection of blood within the external ear tissues, commonly resulting from trauma such as contact sports.

Symptoms include ear pain, swelling, discoloration, and tenderness, with potential for ear deformity if untreated.

Diagnosis is primarily clinical, utilizing physical and otoscopic examination. Imaging is rarely required unless complex trauma is suspected.

First-line treatment involves incision and drainage of the hematoma, followed by compression and possible antibiotic therapy to prevent infection.

Second-line therapies include repeated evacuation and surgical intervention in cases of recurrent hematoma or complications.

Monitoring and follow-up are essential to ensure proper healing and to detect any complications early.

Complications of untreated or poorly managed pinna hematoma include cartilage necrosis, chondritis, deformity, and infection.

162. Presbycusis

1. Detailed Definition of Presbycusis

Presbycusis is the gradual, progressive hearing loss that occurs as a natural part of the aging process. It is the most common type of sensorineural hearing loss in older adults, typically affecting both ears. Presbycusis results from age-related changes in the inner ear (cochlea), auditory nerve, and central auditory pathways. These changes can include the loss of hair cells in the cochlea, degeneration of the auditory nerve, and alterations in brain function related to hearing.

Presbycusis is generally characterized by high-frequency hearing loss, making it difficult to hear high-pitched sounds such as consonants (e.g., "s," "f," "th"). It can significantly impact communication, social interactions, and overall quality of life.

2. Common Presenting Complaints and Symptoms

Patients with presbycusis typically present with:

a) Gradual Hearing Loss:

Description: Progressive difficulty hearing, especially in high frequencies.

Impact: Challenges in understanding speech, particularly in noisy environments.

b) Difficulty Understanding Speech:

Description: Struggling to follow conversations, especially with multiple speakers or background noise.

Impact: May require others to repeat themselves or speak louder.

c) **Tinnitus:**

Description: Persistent ringing, buzzing, or hissing sounds in the ears.

Impact: Can be distressing and affect concentration and sleep.

d) **Social Withdrawal:**

Description: Avoidance of social situations due to difficulty hearing and frustration.

Impact: May lead to isolation and decreased quality of life.

e) **Feeling of Fullness in the Ears:**

Description: Sensation of pressure or fullness, though less common.

Impact: May contribute to discomfort and further hearing difficulties.

f) **Balance Issues** (rare):

Description: Although primarily a hearing disorder, severe presbycusis can occasionally affect balance.

Impact: Increased risk of falls, especially in the elderly.

3. First-Line Investigations

The diagnosis of presbycusis is primarily clinical but is supported by specific audiological assessments.

a) **Pure Tone Audiometry (PTA):**

What it examines: Measures hearing thresholds across a range of frequencies.

Purpose: Identifies the degree and pattern of hearing loss, typically high-frequency sensorineural hearing loss.

b) **Speech Audiometry:**

What it examines: Assesses the ability to recognize and understand speech.

Purpose: Evaluates functional hearing ability and speech discrimination scores.

c) **Tympanometry:**

What it examines: Assesses middle ear function and the mobility of the tympanic membrane.

Purpose: Rules out conductive hearing loss components, such as otitis media with effusion.

d) **Otoacoustic Emissions (OAEs):**

What it examines: Measures sound waves produced by the inner ear's hair cells.

Purpose: Confirms cochlear (hair cell) function; reduced or absent OAEs indicate cochlear damage.

e) **Audiogram Interpretation:**

What it examines: Analyzes the audiometric pattern for characteristic presbycusis features.

Purpose: Differentiates presbycusis from other types of hearing loss, such as noise-induced or sudden sensorineural hearing loss.

4. Explanation of Investigations

a) Pure Tone Audiometry (PTA):

Procedure: The patient listens to tones at various frequencies and volumes through headphones and indicates when they can hear each tone.

Findings in Presbycusis: Progressive, bilateral sensorineural hearing loss, especially at high frequencies (e.g., 4000 Hz and above).

b) Speech Audiometry:

Procedure: The patient repeats spoken words or sentences at varying volumes.

Findings in Presbycusis: Reduced speech discrimination scores, particularly in noisy environments.

c) Tympanometry:

Procedure: Assesses the movement of the tympanic membrane by varying air pressure in the ear canal.

Findings in Presbycusis: Typically normal in sensorineural hearing loss; abnormal results may indicate a mixed hearing loss or concurrent middle ear pathology.

d) Otoacoustic Emissions (OAEs):

Procedure: Sounds are played into the ear, and the echoes produced by the cochlea are measured.

Findings in Presbycusis: Reduced or absent emissions, indicating hair cell loss or dysfunction.

5. Diagnostic Criteria for Presbycusis

The diagnosis of presbycusis is based on:

Age-Related Hearing Decline: Typically affecting individuals over 60 years old.

Symmetrical Sensorineural Hearing Loss: Hearing loss is generally bilateral and symmetrical.

High-Frequency Hearing Loss: Predominantly affects higher frequencies first.

Gradual Onset: Symptoms develop slowly over time without acute episodes.

Audiometric Pattern: Pure tone audiometry shows a sloping audiogram with greater loss at higher frequencies.

Exclusion of Other Causes: Rule out other types of hearing loss (e.g., conductive, mixed, sudden sensorineural) through clinical evaluation and appropriate investigations.

According to **NICE guidelines**, presbycusis is diagnosed clinically in the context of age and confirmed with audiometric testing, ensuring that other potential causes of hearing loss are excluded.

6. First-Line Therapy According to Guidelines

Management of presbycusis focuses on improving communication, reducing the impact on quality of life, and addressing any underlying contributing factors.

a) Hearing Aids:

Action: Use of amplification devices tailored to the individual's specific hearing loss pattern.

Outcome: Improves hearing ability, enhances speech understanding, and facilitates better communication.

b) Assistive Listening Devices:

Action: Devices such as amplified telephones, FM systems, and alerting devices.

Outcome: Enhances hearing in specific situations, such as conversations, watching television, or in noisy environments.

c) Communication Strategies:

Action: Educating patients on effective communication techniques, such as facing the speaker, reducing background noise, and using visual cues.

Outcome: Improves interpersonal communication and reduces misunderstandings.

d) Cognitive Behavioral Therapy (CBT):

Action: Therapy to help patients cope with the psychosocial impacts of hearing loss, such as anxiety or depression.

Outcome: Enhances mental well-being and adjusts coping strategies for dealing with hearing impairment.

e) Regular Audiometric Monitoring:

Action: Periodic hearing assessments to monitor progression and adjust hearing aids as needed.

Outcome: Ensures optimal hearing aid performance and timely adjustments based on changes in hearing levels.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Severe Cognitive Impairment: Patients with significant cognitive deficits may have difficulty using hearing aids effectively.

Severe Manual Dexterity Issues: Difficulty in handling and adjusting hearing aids may limit their use.

b) Second-Line Therapy:

Cochlear Implants:

Indication: For patients with severe to profound sensorineural hearing loss who do not benefit sufficiently from hearing aids.

Outcome: Provides significant hearing improvement and better speech understanding in noisy environments.

Bone-Anchored Hearing Systems (BAHS):

Indication: For patients with conductive or mixed hearing loss, single-sided deafness, or those who cannot use conventional hearing aids.

Outcome: Enhances sound transmission directly to the cochlea, improving hearing in specific scenarios.

Middle Ear Implants:

Indication: Alternative for patients who cannot tolerate conventional hearing aids.

Outcome: Provides hearing amplification through direct mechanical stimulation of the middle ear structures.

Speech and Language Therapy:

Indication: For patients experiencing communication difficulties despite hearing aid use.

Outcome: Improves speech comprehension and communication skills through targeted exercises and strategies.

Tinnitus Management:

Action: Use of sound therapy, tinnitus retraining therapy (TRT), or cognitive behavioral therapy (CBT) for associated tinnitus.

Outcome: Reduces the perception of tinnitus and its impact on quality of life.

8. Routine Monitoring and Follow-Up

a) Regular Audiometric Assessments:

Action: Conduct hearing tests every 1-2 years or as needed based on symptoms.

Outcome: Monitors progression of hearing loss and ensures hearing aids remain appropriately fitted and effective.

b) Hearing Aid Maintenance:

Action: Regular check-ups for hearing aid adjustments, battery replacements, and troubleshooting.

Outcome: Maintains optimal performance and longevity of hearing aids.

c) Monitoring for Comorbidities:

Action: Assess for associated conditions such as depression, anxiety, or social isolation.

Outcome: Provides holistic care addressing both hearing loss and its psychosocial impacts.

d) Patient Education and Support:

Action: Provide ongoing education about hearing loss management, available resources, and support groups.

Outcome: Empowers patients to effectively manage their hearing loss and seek support when needed.

e) Assessment for Surgical Interventions:

Action: Evaluate the need for cochlear implants or other surgical options in cases of severe hearing loss unresponsive to conventional treatments.

Outcome: Ensures timely referral and intervention to maximize hearing restoration.

9. Complications of Presbycusis

a) Social Isolation and Depression:

Description: Difficulty in communication can lead to withdrawal from social activities and relationships.

Consequence: Increases the risk of depression and decreased quality of life.

b) Cognitive Decline:

Description: Chronic hearing loss is associated with an increased risk of cognitive impairment and dementia.

Consequence: May accelerate cognitive decline and affect overall mental function.

c) Falls and Accidents:

Description: Hearing loss can impair spatial awareness and environmental awareness.

Consequence: Increases the risk of falls and related injuries, particularly in the elderly.

d) Workplace Challenges:

Description: Difficulty in understanding instructions and communicating with colleagues.

Consequence: May affect job performance and career progression.

e) Reduced Safety Awareness:

Description: Inability to hear alarms, warnings, or approaching vehicles.

Consequence: Increases the risk of accidents and emergencies.

f) Tinnitus:

Description: Persistent ringing or buzzing can cause significant distress.

Consequence: May lead to sleep disturbances, concentration issues, and psychological stress.

g) **Decreased Hearing Aid Compliance:**

Description: Some patients may find hearing aids uncomfortable or stigmatizing.

Consequence: Reduced use of hearing aids can exacerbate hearing loss and its associated complications.

Summary of Key Points for Presbycusis

Presbycusis is age-related, progressive sensorineural hearing loss affecting both ears, primarily in high frequencies.

Symptoms include gradual hearing loss, difficulty understanding speech, tinnitus, and social withdrawal.

Diagnosis is clinical, supported by audiometry, speech audiometry, tympanometry, and otoacoustic emissions.

First-line treatment involves the use of hearing aids, assistive listening devices, and communication strategies to improve hearing and communication.

Second-line therapies include cochlear implants, bone-anchored hearing systems, and speech therapy for refractory cases.

Routine monitoring is essential to track hearing loss progression, maintain hearing aid effectiveness, and address psychosocial impacts.

Complications can include social isolation, depression, cognitive decline, increased risk of falls, and reduced safety awareness.

Management focuses on improving communication, enhancing quality of life, and addressing associated mental health concerns.

163. Rhinosinusitis and Nasal Polyps

1. Detailed Definition of Rhinosinusitis and Nasal Polyps

Rhinosinusitis is an inflammation of the nasal cavity and paranasal sinuses. It can be classified based on duration and etiology:

Acute Rhinosinusitis (ARS): Lasts less than 4 weeks, typically following a viral upper respiratory tract infection.

Subacute Rhinosinusitis: Lasts between 4 to 12 weeks.

Chronic Rhinosinusitis (CRS): Persists for 12 weeks or longer, often associated with persistent inflammation, structural abnormalities, or immune system dysfunction.

Nasal Polyps are non-cancerous, soft, painless growths on the lining of the nasal passages or sinuses. They result from chronic inflammation and are commonly associated with conditions like chronic rhinosinusitis, asthma, aspirin sensitivity (Samter's triad), and allergic fungal sinusitis. Nasal polyps can obstruct airflow, lead to recurrent infections, and cause a decreased sense of smell.

2. Common Presenting Complaints and Symptoms

Rhinosinusitis can present with a variety of symptoms depending on its severity and duration.

Acute Rhinosinusitis (ARS):

Nasal Congestion or Obstruction: Difficulty breathing through the nose.

Facial Pain or Pressure: Often worse when bending forward.

Purulent Nasal Discharge: Thick, colored mucus from the nose or posterior drainage into the throat.

Reduced Sense of Smell (Hyposmia).

Fever: Common in bacterial ARS.

Cough: Particularly at night due to postnasal drip.

Chronic Rhinosinusitis (CRS):

Nasal Obstruction: Persistent difficulty breathing through the nose.

Facial Pressure or Pain: Ongoing discomfort in the face.

Chronic Nasal Discharge: Mucus drainage lasting more than 12 weeks.

Reduced or Altered Sense of Smell (Hyposmia or Anosmia).

Postnasal Drip: Continuous mucus dripping down the throat.

Fatigue and Headache: Due to persistent symptoms.

Nasal Polyps:

Nasal Obstruction: Blockage of nasal passages leading to difficulty breathing through the nose.

Chronic Nasal Discharge: Often without significant color changes.

Loss of Smell (Anosmia): Complete or partial loss of the sense of smell.

Facial Pressure: Mild discomfort or fullness in the face.

Snoring or Sleep Apnea: Due to airway obstruction.

3. First-Line Investigations

Rhinosinusitis and **Nasal Polyps** are primarily diagnosed based on clinical evaluation, but certain investigations can support the diagnosis and assess the extent of the disease.

a) Clinical Examination:

What it examines: Inspection of the nasal cavity using a nasal speculum or endoscopy.

Purpose: Identifies signs of inflammation, purulent discharge, polyps, or anatomical abnormalities.

b) Nasal Endoscopy:

What it examines: Detailed visualization of the nasal passages and sinuses using a flexible or rigid endoscope.

Purpose: Assesses the extent of inflammation, presence and size of nasal polyps, and identifies anatomical variations or complications.

c) Imaging Studies:

CT Scan of the Paranasal Sinuses:

What it examines: Detailed bone and soft tissue structures of the sinuses.

Purpose: Confirms the diagnosis of CRS, assesses the extent of sinus involvement, identifies anatomical variants, polyps, or complications like orbital or intracranial extension.

MRI of the Sinuses (if fungal infection or intracranial extension is suspected):

What it examines: Soft tissue details and involvement of adjacent structures.

Purpose: Differentiates between inflammatory and neoplastic processes, assesses for complications.

d) Allergy Testing (if allergic rhinitis is suspected):

What it examines: Identification of specific allergens.

Purpose: Guides management in patients with CRS and comorbid allergic conditions.

e) Blood Tests:

What it measures: Inflammatory markers (e.g., ESR, CRP).

Purpose: Helps differentiate between bacterial and non-bacterial causes, especially in acute cases.

4. Explanation of Investigations

a) Clinical Examination and Nasal Endoscopy:

Procedure: The clinician inspects the nasal cavity for redness, swelling, discharge, and the presence of polyps. Nasal endoscopy provides a magnified view, allowing for better assessment of mucosal health and polyp characteristics.

Findings in Rhinosinusitis: Red, swollen mucosa; purulent discharge; polyps in CRS.

Findings in Nasal Polyps: Smooth, pale, non-tender, and grape-like masses within the nasal passages.

b) CT Scan of the Paranasal Sinuses:

Procedure: Non-contrast axial and coronal imaging to evaluate bone structures and soft tissues.

Findings in CRS: Mucosal thickening, opacification of sinuses, air-fluid levels, and presence of nasal polyps.

Utility: Essential for surgical planning in refractory cases or when anatomical variations are present.

c) MRI of the Sinuses:

Procedure: Uses magnetic fields to create detailed images of soft tissues.

Findings: Useful in distinguishing fungal sinusitis (which may show hyperdense areas on MRI) or detecting intracranial complications such as meningitis or brain abscesses.

5. Diagnostic Criteria for Rhinosinusitis and Nasal Polyps

Rhinosinusitis:

Acute Rhinosinusitis (ARS):

Duration: Symptoms lasting less than 4 weeks.

Criteria: At least two of the following symptoms:

Nasal congestion or obstruction.

Facial pain or pressure.

Purulent nasal discharge.

Reduced sense of smell.

Chronic Rhinosinusitis (CRS):

Duration: Symptoms lasting 12 weeks or longer.

Criteria: Presence of two or more of the following symptoms:

Nasal obstruction.

Facial pain or pressure.

Nasal discharge.

Reduced sense of smell.

Endoscopic or Imaging Findings: Evidence of sinus inflammation, polyps, or mucosal changes on endoscopy or CT scan.

Nasal Polyps:

Clinical Features:

Bilateral nasal obstruction.

Chronic nasal discharge.

Loss of sense of smell.

Presence of smooth, non-tender, grape-like masses within the nasal passages observed on endoscopy.

Associated Conditions:

Often coexist with CRS, asthma, and aspirin-exacerbated respiratory disease (Samter's triad).

According to **NICE guidelines**, the diagnosis is primarily clinical, supported by nasal endoscopy and imaging as needed to assess the extent and guide management.

6. First-Line Therapy According to Guidelines

Rhinosinusitis and **Nasal Polyps** management depends on the type (acute vs. chronic) and severity.

Acute Rhinosinusitis (ARS): a) Symptomatic Treatment:

Analgesics and Antipyretics: **Paracetamol** or **ibuprofen** for pain and fever.

Nasal Decongestants: **Pseudoephedrine** oral or **oxymetazoline** nasal sprays for short-term relief (not exceeding 3-5 days to avoid rebound congestion).

Saline Nasal Irrigation: Helps clear mucus and debris.

b) **Antibiotic Therapy** (if bacterial infection is suspected):

Criteria for Antibiotics:

Severe symptoms (e.g., high fever $>39^{\circ}\text{C}$, purulent nasal discharge) lasting less than 10 days.

Persistent symptoms beyond 7 days without improvement.

Double worsening (initial improvement followed by worsening symptoms).

First-Line Antibiotic: **Amoxicillin** 500 mg three times daily for 5-7 days.

Alternative: **Amoxicillin-Clavulanate** for penicillin-allergic patients or in areas with high resistance rates.

Chronic Rhinosinusitis (CRS): a) Intranasal Corticosteroids:

Action: Reduce inflammation and polyp size.

Examples: **Fluticasone**, **mometasone**, or **budesonide** nasal sprays used daily.

Outcome: Improves symptoms and reduces polyp size.

b) **Saline Nasal Irrigation:**

Action: Regular irrigation to remove mucus and allergens.

Outcome: Enhances symptom relief and improves mucociliary clearance.

c) **Oral or Systemic Corticosteroids** (for severe CRS with nasal polyps):

Action: Short courses of oral corticosteroids like **prednisolone**.

Outcome: Reduces polyp size and inflammation, providing temporary symptom relief.

d) **Antibiotics:**

Action: Course of antibiotics such as **amoxicillin-clavulanate** or **doxycycline** if bacterial infection is suspected.

Outcome: Treats underlying bacterial infections contributing to inflammation.

e) **Leukotriene Receptor Antagonists:**

Action: **Montelukast** may be used in patients with CRS and comorbid asthma.

Outcome: Reduces inflammation and symptom severity.

Nasal Polyps: a) **Intranasal Corticosteroids:**

Action: First-line treatment to reduce polyp size and inflammation.

Outcome: Improves nasal obstruction, drainage, and sense of smell.

b) **Oral or Systemic Corticosteroids:**

Action: Used for rapid reduction of large polyps or severe symptoms.

Outcome: Provides quick symptom relief and polyp shrinkage but is limited by potential side effects.

c) **Biologic Therapy** (in refractory cases):

Action: Monoclonal antibodies like **dupilumab** for patients with severe CRSwNP (Chronic Rhinosinusitis with Nasal Polyps) who do not respond to standard treatments.

Outcome: Reduces polyp size and symptom burden.

d) **Endoscopic Sinus Surgery:**

Action: Surgical removal of polyps and opening of blocked sinus pathways.

Outcome: Improves sinus drainage, relieves symptoms, and may enhance the effectiveness of medical therapies post-surgery.

7. Common Contraindications and Second-Line Therapy

a) **Contraindications:**

Nasal Decongestant Overuse: Prolonged use of topical decongestants can lead to rhinitis medicamentosa.

Systemic Corticosteroids: Contraindicated in patients with systemic infections, uncontrolled diabetes, or osteoporosis without specialist oversight.

Allergic Reactions: Allergies to specific medications used in treatment (e.g., amoxicillin).

b) **Second-Line Therapy:**

Leukotriene Receptor Antagonists:

Indication: For patients with CRS and comorbid asthma or aspirin-exacerbated respiratory disease.

Outcome: Reduces inflammation and improves symptoms when corticosteroids are insufficient.

Biologic Agents:

Indication: Severe CRSwNP unresponsive to standard medical therapies.

Examples: **Dupilumab** targets interleukin-4 and interleukin-13 pathways to reduce inflammation.

Outcome: Significant reduction in polyp size and symptom improvement.

Endoscopic Sinus Surgery:

Indication: Persistent CRS symptoms despite maximal medical therapy, or large nasal polyps causing significant obstruction.

Outcome: Enhances sinus drainage, removes polyps, and improves symptom control, allowing for better efficacy of postoperative medical therapies.

Balloon Sinuplasty:

Indication: For selected patients with CRS without extensive polyps or bony obstruction.

Outcome: Minimally invasive procedure to dilate sinus pathways, improving drainage and reducing symptoms.

Aspirin Desensitization:

Indication: In patients with Samter's triad (CRSwNP, asthma, and aspirin sensitivity).

Outcome: Reduces the frequency of CRS exacerbations and polyp growth.

8. Routine Monitoring and Follow-Up**a) Regular Clinical Reviews:**

Action: Scheduled follow-up appointments to assess symptom progression, treatment response, and adherence.

Outcome: Ensures timely adjustments to therapy and early detection of complications or treatment failures.

b) Repeat Nasal Endoscopy:

Action: Periodic endoscopic examinations to monitor polyp size, sinus inflammation, and effectiveness of medical or surgical treatments.

Outcome: Guides further management decisions and detects recurrence early.

c) Audiometric Testing:

Action: Hearing assessments in patients with CRS, especially if nasal polyps are present.

Outcome: Identifies hearing loss and evaluates the impact of treatment on auditory function.

d) Imaging Studies:

Action: Follow-up CT scans or MRIs in refractory cases or after surgical interventions.

Outcome: Assesses the anatomical success of treatments and identifies any residual or recurrent disease.

e) Patient Education and Self-Management:

Action: Educate patients on nasal irrigation techniques, avoidance of environmental irritants, and adherence to medical therapies.

Outcome: Empowers patients to actively participate in their care, improving treatment outcomes and reducing recurrence rates.

f) Monitoring for Side Effects:

Action: Regular assessment for side effects of long-term corticosteroid use or other medications.

Outcome: Minimizes adverse effects and maintains patient safety during ongoing treatment.

9. Complications of Rhinosinusitis and Nasal Polyps

a) Orbital Complications:

Description: Infection can spread to the orbit, causing cellulitis, abscess, or orbital apex syndrome.

Consequence: Can lead to vision loss, ophthalmoplegia, and intracranial spread if untreated.

b) Intracranial Complications:

Description: Spread of infection to the brain, leading to meningitis, brain abscess, or cavernous sinus thrombosis.

Consequence: Life-threatening conditions requiring urgent intervention.

c) Osteomyelitis of the Facial Bones:

Description: Bone infection, particularly of the frontal or ethmoid bones.

Consequence: Requires aggressive antibiotic therapy and possible surgical debridement.

d) Chronic Rhinosinusitis with Nasal Polyps (CRSwNP):

Description: Persistent inflammation and polyp formation leading to recurrent symptoms.

Consequence: May necessitate repeated medical or surgical treatments and is associated with asthma and aspirin sensitivity.

e) Anosmia or Hyposmia:

Description: Persistent loss or reduction of the sense of smell.

Consequence: Affects quality of life and can be a marker for disease severity or recurrence.

f) Dehydration and Electrolyte Imbalance:

Description: Due to persistent fever, reduced oral intake, or excessive use of diuretics in CRS management.

Consequence: Requires medical intervention to correct imbalances and prevent complications.

g) Recurrent Infections:

Description: Persistent or recurrent bacterial infections despite treatment.

Consequence: Indicates underlying issues such as immune dysfunction or anatomical abnormalities requiring further investigation.

h) Psychosocial Impact:

Description: Chronic symptoms can lead to anxiety, depression, and social withdrawal.

Consequence: Necessitates a holistic approach to patient care, addressing mental health alongside physical symptoms.

Summary of Key Points for Rhinosinusitis and Nasal Polyps

Rhinosinusitis is the inflammation of the nasal cavity and paranasal sinuses, categorized as acute, subacute, or chronic based on duration.

Nasal Polyps are non-cancerous growths associated with chronic inflammation, often seen in CRS, asthma, and aspirin sensitivity.

Symptoms vary by type, with ARS presenting with acute pain and discharge, CRS with persistent congestion and discharge, and nasal polyps with obstruction and loss of smell.

Diagnosis is clinical, supported by nasal endoscopy and imaging (CT scan) to assess disease extent and guide management.

First-line treatments include symptomatic relief for ARS, intranasal corticosteroids and saline irrigation for CRS, and surgical removal for significant nasal polyps.

Second-line therapies encompass biologic agents, advanced surgical interventions, and management of associated conditions like asthma.

Routine monitoring involves regular clinical reviews, repeat endoscopy, and audiometric testing to ensure effective treatment and manage complications.

Complications can range from orbital and intracranial infections to chronic inflammation, hearing loss, and significant psychosocial impacts.

NICE guidelines emphasize a stepwise approach to management, prioritizing conservative treatments and escalating to surgical or advanced medical therapies as needed to optimize patient outcomes and prevent complications.

164. Tonsillitis and Pharyngitis

1. Detailed Definition of Tonsillitis and Pharyngitis

Tonsillitis is the inflammation of the palatine tonsils, which are lymphoid tissues located on both sides at the back of the throat. **Pharyngitis** is the inflammation of the pharynx, the area behind the nasal cavities and mouth that leads to the esophagus and larynx. Both conditions often occur together as **tonsillopharyngitis** and are commonly caused by infectious agents, either viral or bacterial.

Viral Causes: The majority of cases are viral, including pathogens like adenoviruses, rhinoviruses, influenza viruses, and Epstein-Barr virus (EBV).

Bacterial Causes: Group A beta-hemolytic Streptococcus (*Streptococcus pyogenes*) is the most common bacterial cause, leading to streptococcal pharyngitis.

The conditions are highly contagious and spread through respiratory droplets or direct contact with infected secretions.

2. Common Presenting Complaints and Symptoms

Patients with tonsillitis and pharyngitis typically present with:

a) **Sore Throat (Pharyngodynia):**

Description: Pain or discomfort in the throat, especially when swallowing (odynophagia).

Impact: May interfere with eating, drinking, and speaking.

b) **Fever:**

Description: Elevated body temperature, often above 38°C.

Impact: May be accompanied by chills and general malaise.

c) **Enlarged and Red Tonsils:**

Description: Swollen tonsils that may have white or yellow exudates (pus).

Impact: Visible upon examination of the throat.

d) **Swollen Cervical Lymph Nodes (Lymphadenopathy):**

Description: Tender, enlarged lymph nodes in the neck.

Impact: May cause discomfort or pain when moving the neck.

e) **Headache and Body Aches:**

Description: Generalized aches due to systemic infection.

f) **Difficulty Swallowing (Dysphagia):**

Description: Painful or uncomfortable swallowing.

g) **Muffled or Altered Voice:**

Description: Changes in voice quality due to swollen tonsils.

h) **Bad Breath (Halitosis):**

Description: Foul-smelling breath resulting from bacterial infection.

i) **Erythematous Pharynx:**

Description: Reddened throat upon examination.

j) **Cough and Nasal Symptoms** (more common in viral infections):

Description: Runny nose, sneezing, or cough.

3. First-Line Investigations

Diagnosis is primarily clinical, but certain investigations may help differentiate between viral and bacterial causes, guiding appropriate management.

a) **Clinical Examination:**

What it examines: Inspection of the throat, tonsils, and lymph nodes.

Purpose: Identifies signs of inflammation, exudates, and lymphadenopathy.

b) **Centor Criteria:**

What it assesses: A scoring system based on clinical features.

Criteria:

Tonsillar exudates.

Tender anterior cervical lymphadenopathy.

Fever over 38°C.

Absence of cough.

Purpose: Helps predict the likelihood of streptococcal infection.

c) **Rapid Antigen Detection Test (RADT):**

What it examines: Presence of Group A Streptococcus antigens.

Purpose: Provides quick results to confirm streptococcal pharyngitis.

d) **Throat Swab Culture:**

What it examines: Laboratory culture of throat swab specimens.

Purpose: Identifies bacterial pathogens; considered the gold standard but results take 24-48 hours.

e) **Full Blood Count (FBC):**

What it measures: White blood cell count and differential.

Purpose: May show elevated white cells in bacterial infections; lymphocytosis in viral infections.

f) Monospot Test (if infectious mononucleosis is suspected):

What it examines: Heterophile antibodies indicating EBV infection.

Purpose: Differentiates infectious mononucleosis from bacterial tonsillitis.

4. Explanation of Investigations

a) Clinical Examination and Centor Criteria:

Procedure: Physical assessment of throat and neck, scoring based on the presence of specific signs.

Interpretation:

Score 0-1: Low likelihood of streptococcal infection; no antibiotics or further testing needed.

Score 2-3: Moderate likelihood; consider RADT or delayed antibiotic prescription.

Score 4: High likelihood; consider immediate antibiotics or confirm with RADT.

b) Rapid Antigen Detection Test (RADT):

Procedure: Swab the tonsils and posterior pharynx; results available in minutes.

Sensitivity: Approximately 70-90%; negative results may need confirmation with culture in high-risk patients.

c) Throat Swab Culture:

Procedure: Swab the tonsillar area and culture in the lab.

Utility: Definitive identification of bacterial pathogens; guides antibiotic selection.

d) Monospot Test:

Procedure: Blood test to detect heterophile antibodies.

Utility: Positive in infectious mononucleosis; negative in typical bacterial tonsillitis.

5. Diagnostic Criteria for Tonsillitis and Pharyngitis

Acute Tonsillitis/Pharyngitis:

Symptoms: Sore throat, fever, swollen tonsils with or without exudate, tender cervical lymphadenopathy.

Clinical Signs: Red, inflamed pharynx and tonsils upon examination.

Centor or FeverPAIN Criteria: Used to assess likelihood of streptococcal infection and guide management.

Streptococcal Pharyngitis:

Features: Sudden onset of sore throat, fever, tonsillar exudates, tender cervical lymph nodes, absence of cough.

Confirmation: Positive RADT or throat culture for Group A Streptococcus.

Viral Pharyngitis:

Features: Gradual onset, associated with cough, rhinorrhea, hoarseness, conjunctivitis.

Confirmation: Negative RADT, supportive viral symptoms.

According to **NICE guidelines**, routine use of RADT or throat swabs is not recommended in primary care. Clinical scoring systems like Centor or FeverPAIN should guide antibiotic prescribing decisions.

6. First-Line Therapy According to Guidelines

Management depends on the likely cause (viral vs. bacterial) and severity of symptoms.

a) Symptomatic Treatment (First-Line for Most Cases):

Analgesics and Antipyretics:

Medications: Paracetamol or ibuprofen.

Action: Relieve pain and reduce fever.

Hydration and Rest:

Action: Encourage fluid intake and adequate rest.

Outcome: Supports immune function and recovery.

Throat Lozenges or Sprays:

Action: Provide temporary relief of sore throat.

b) Antibiotic Therapy (if bacterial infection is suspected or confirmed):

First-Line Antibiotic: Phoxymethylpenicillin (Penicillin V).

Dose:

Adults: 500 mg two to four times daily for 10 days.

Children: Dose adjusted by age and weight.

Alternative (for penicillin-allergic patients): Clarithromycin or Erythromycin.

Dose:

Clarithromycin: 250-500 mg twice daily for 5 days.

Criteria for Antibiotic Use:

Centor score ≥ 3 or FeverPAIN score ≥ 4 .

Features of severe infection.

High-risk patients (e.g., immunocompromised).

c) Delayed Prescription Strategy:

Action: Provide a prescription but advise to wait 2-3 days before using it if symptoms do not improve.

Outcome: Reduces unnecessary antibiotic use.

d) Patient Education:

Action: Inform about the natural course of the illness, expected duration (usually 1 week), and signs of complications.

Outcome: Sets realistic expectations and encourages appropriate use of medications.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Penicillin Allergy: Avoid penicillin antibiotics in allergic patients; use macrolides instead.

Aspirin Use in Children: Do not use aspirin in patients under 16 due to the risk of Reye's syndrome.

b) Second-Line Therapy:

Alternative Antibiotics:

Cefuroxime or **Clindamycin** for recurrent infections or treatment failures.

Dose and duration: As per local guidelines and patient-specific factors.

Referral to ENT Specialist:

Indication: Recurrent tonsillitis (e.g., ≥ 7 episodes in one year), peritonsillar abscess (quinsy), or suspicion of malignancy.

Outcome: Consideration for tonsillectomy or further investigations.

8. Routine Monitoring and Follow-Up

a) Symptom Monitoring:

Action: Advise patients to monitor symptoms and seek medical attention if they worsen or do not improve within 3-5 days.

Outcome: Early detection of complications or need for alternative treatments.

b) Reassessment for Antibiotic Necessity:

Action: In cases of delayed prescriptions, reassess if symptoms persist or worsen.

Outcome: Ensures antibiotics are used appropriately.

c) Follow-Up for Complications:

Action: Arrange follow-up for patients at risk of complications (e.g., immunocompromised individuals).

Outcome: Timely intervention if complications develop.

9. Complications of Tonsillitis and Pharyngitis

a) Peritonsillar Abscess (Quinsy):

Description: Collection of pus between the tonsil and the pharyngeal muscles.

Symptoms: Severe unilateral throat pain, trismus (difficulty opening the mouth), muffled voice, uvular deviation.

Management: Requires urgent ENT referral for drainage and intravenous antibiotics.

b) Rheumatic Fever:

Description: Inflammatory disease affecting the heart, joints, skin, and brain, following untreated streptococcal infection.

Prevention: Adequate antibiotic treatment of streptococcal pharyngitis.

c) Post-Streptococcal Glomerulonephritis:

Description: Inflammation of the kidneys following streptococcal infection.

Symptoms: Hematuria, proteinuria, edema, hypertension.

d) Scarlet Fever:

Description: Streptococcal infection characterized by a red rash, fever, and "strawberry tongue."

Management: Antibiotic therapy to prevent complications.

e) Otitis Media and Sinusitis:

Description: Spread of infection to the middle ear or sinuses.

f) Deep Neck Space Infections:

Description: Spread of infection leading to cellulitis or abscesses in the neck spaces.

Symptoms: Neck swelling, pain, airway obstruction.

Management: Requires urgent medical attention.

g) Obstructive Sleep Apnea (in chronic tonsillar hypertrophy):

Description: Enlarged tonsils obstruct the airway during sleep.

Symptoms: Snoring, daytime sleepiness, behavioral issues in children.

Summary of Key Points for Tonsillitis and Pharyngitis

Tonsillitis and pharyngitis are common infections of the throat, often viral but sometimes bacterial (notably Group A Streptococcus).

Symptoms include sore throat, fever, swollen tonsils (with or without exudate), and tender cervical lymphadenopathy.

Diagnosis is primarily clinical, with tools like the **Centor criteria** guiding management decisions.

First-line treatment focuses on **symptomatic relief** with analgesics and antipyretics; antibiotics are reserved for likely bacterial cases.

Phenoxymethylpenicillin is the antibiotic of choice for streptococcal pharyngitis; alternatives are used for penicillin-allergic patients.

Complications can be serious and include peritonsillar abscess, rheumatic fever, and glomerulonephritis.

Patient education on symptom management, expected illness course, and when to seek further medical attention is crucial.

NICE guidelines advocate for prudent antibiotic use to combat resistance and emphasize the importance of clinical assessment in management decisions.

165. Vocal Cord Paralysis

1. Detailed Definition of Vocal Cord Paralysis

Vocal cord paralysis (also known as **vocal fold paralysis**) is a condition where one or both of the vocal cords (vocal folds) cannot move properly due to nerve damage or dysfunction. The vocal cords are essential for voice production, breathing, and protecting the airway during swallowing. Paralysis can be unilateral (one vocal cord) or bilateral (both vocal cords), and can result from various etiologies, including neurological disorders, surgical injury, trauma, tumors, or idiopathic causes.

The paralysis occurs when the recurrent laryngeal nerve (a branch of the vagus nerve) or the superior laryngeal nerve is damaged or impaired. This leads to an inability of the affected vocal cord(s) to move to the midline during phonation, resulting in voice changes, aspiration, and airway compromise.

2. Common Presenting Complaints and Symptoms

The symptoms of vocal cord paralysis depend on whether one or both vocal cords are affected and the position of the paralyzed cord(s).

Unilateral Vocal Cord Paralysis:

Hoarseness or Breathiness: Voice may be weak, breathy, or hoarse due to incomplete glottic closure during phonation.

Voice Fatigue: Increased effort required to speak, leading to fatigue when talking.

Dyspnea on Exertion: Shortness of breath during physical activity due to reduced airway protection.

Choking or Coughing While Eating: Aspiration of food or liquids due to impaired closure of the glottis during swallowing.

Weak Cough: Inability to generate a strong cough to clear secretions.

Throat Clearing: Frequent need to clear the throat due to accumulation of secretions.

Bilateral Vocal Cord Paralysis:

Inspiratory Stridor: High-pitched, noisy breathing sounds due to airway obstruction, especially during inspiration.

Dyspnea at Rest: Difficulty breathing even without exertion; can be life-threatening.

Voice Changes: Voice may be relatively normal or mildly affected.

Aspiration: Less common than in unilateral paralysis but can occur.

Other associated symptoms may include:

Dysphagia: Difficulty swallowing.

Weight Loss: Due to reduced oral intake or aspiration-related issues.

History of Recent Surgery: Especially thyroid, neck, or chest surgery.

Neurological Symptoms: If associated with neurological conditions (e.g., stroke, multiple sclerosis).

3. First-Line Investigations

The aim of investigations is to confirm the diagnosis, assess the severity, identify the underlying cause, and guide management.

a) Laryngoscopy (Flexible or Rigid Endoscopy):

What it examines: Direct visualization of the larynx and vocal cord movement.

Purpose: Confirms the diagnosis by observing the mobility of the vocal cords during breathing and phonation.

b) Laryngeal Electromyography (EMG):

What it examines: Measures electrical activity of the laryngeal muscles.

Purpose: Assesses the integrity of the nerves supplying the vocal cords and differentiates paralysis from mechanical fixation.

c) Imaging Studies:

Neck and Chest CT or MRI:

What it examines: Detailed imaging of the neck, mediastinum, and skull base.

Purpose: Identifies structural lesions (e.g., tumors, masses) compressing the recurrent laryngeal nerve or vagus nerve along its course.

Brain MRI (if central causes are suspected):

What it examines: Imaging of the brainstem and cranial nerves.

Purpose: Detects central nervous system lesions affecting the vagus nerve.

d) **Chest X-Ray:**

What it examines: Visualization of the lungs and mediastinum.

Purpose: Screens for lung masses, enlarged heart, or other pathologies that may affect the recurrent laryngeal nerve.

e) **Blood Tests:**

What it measures: Thyroid function tests, inflammatory markers.

Purpose: Evaluates for endocrine disorders (e.g., hypothyroidism) or systemic conditions.

f) **Swallowing Assessment:**

What it examines: Evaluation of swallowing function.

Purpose: Assesses risk of aspiration and guides dietary modifications.

4. Explanation of Investigations

a) **Laryngoscopy:**

This is the primary diagnostic tool for vocal cord paralysis. By visualizing the vocal cords during respiration and phonation, the examiner can assess movement and position of the vocal cords. Unilateral paralysis will show one immobile cord, while bilateral paralysis shows both cords not moving.

b) **Imaging Studies:**

Imaging helps identify possible causes of nerve damage. The recurrent laryngeal nerve has a long course from the brainstem through the neck and chest, making it susceptible to compression or injury along its path. CT and MRI can detect masses, tumors, or structural abnormalities.

5. Diagnostic Criteria for Vocal Cord Paralysis

The diagnosis is based on:

History and Clinical Presentation: Voice changes, breathing difficulties, aspiration symptoms.

Laryngoscopic Findings: Demonstrated immobility of one or both vocal cords.

Exclusion of Mechanical Fixation: Differentiated from joint fixation or muscle disorders via laryngeal EMG.

Identification of Underlying Cause: Through imaging and other investigations.

According to **NICE guidelines**, patients with suspected vocal cord paralysis should be referred to an ENT specialist for prompt evaluation.

6. First-Line Therapy According to Guidelines

Treatment aims to improve voice quality, protect the airway, prevent aspiration, and address the underlying cause.

Unilateral Vocal Cord Paralysis:

a) Voice Therapy (Speech and Language Therapy):

Action: Exercises and techniques to improve voice quality and compensate for the paralyzed cord.

Outcome: Enhances vocal function, reduces strain, and improves communication.

b) Injection Medialization (Vocal Cord Augmentation):

Action: Injection of materials (e.g., hyaluronic acid, collagen, fat) into the paralyzed vocal cord to bulk it up and move it towards the midline.

Outcome: Improves glottic closure during phonation, enhancing voice quality and reducing aspiration risk.

c) Surgical Medialization Laryngoplasty (Thyroplasty Type I):

Action: Surgical implantation of a prosthesis to push the paralyzed vocal cord towards the midline.

Outcome: Provides long-term improvement in voice quality and airway protection.

d) Reinnervation Surgery:

Action: Surgical reinnervation of the paralyzed vocal cord using nerve grafts or muscle-nerve transposition.

Outcome: Aims to restore nerve function and muscle tone over time.

Bilateral Vocal Cord Paralysis:

a) Airway Management:

Action: Ensuring airway patency; may require tracheostomy in severe cases.

Outcome: Secures airway to prevent life-threatening obstruction.

b) Laser Cordotomy or Arytenoidectomy:

Action: Surgical procedures to widen the airway by removing part of the vocal cord or arytenoid cartilage.

Outcome: Improves breathing while attempting to preserve voice quality.

c) Observation:

Action: In cases where recovery of nerve function is anticipated.

Outcome: Avoids unnecessary surgery; patient is closely monitored.

Addressing Underlying Causes:

Action: Treat any identified underlying conditions (e.g., tumor resection, managing neurological disorders).

Outcome: May improve or resolve vocal cord paralysis if the cause is reversible.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Voice Therapy: May be less effective if there is no residual vocal cord movement.

Surgical Procedures: Patients unfit for surgery due to medical comorbidities.

b) Second-Line Therapy:

Botulinum Toxin Injection:

Indication: For cases of spasmodic dysphonia or compensatory muscle hyperactivity.

Outcome: Reduces muscle spasms, improving voice quality.

Permanent Tracheostomy:

Indication: For patients with bilateral vocal cord paralysis who cannot tolerate other interventions.

Outcome: Provides a secure airway but impacts quality of life.

Experimental Treatments:

Indication: Stem cell therapy or gene therapy in research settings.

Outcome: Potential future options but not currently standard care.

8. Routine Monitoring and Follow-Up

a) Regular ENT Reviews:

Action: Monitor vocal cord function, voice quality, and airway status.

Outcome: Detects changes, complications, or recovery of nerve function.

b) Voice Therapy Sessions:

Action: Ongoing speech therapy to optimize voice use.

Outcome: Maximizes functional voice improvements.

c) Swallowing Assessments:

Action: Re-evaluate swallowing safety periodically.

Outcome: Prevents aspiration and associated complications.

d) Imaging Follow-Up:

Action: Repeat imaging if initial studies were inconclusive or to monitor known lesions.

Outcome: Ensures early detection of any progressing conditions.

9. Complications of Vocal Cord Paralysis

a) Aspiration Pneumonia:

Description: Inhalation of food or liquids into the lungs due to impaired glottic closure.

Consequence: Can lead to pneumonia, requiring medical treatment.

b) Airway Obstruction:

Description: In bilateral paralysis, the vocal cords may be in a midline position, causing significant airway narrowing.

Consequence: May result in respiratory distress or emergency situations.

c) Voice Dysfunction:

Description: Persistent hoarseness, breathiness, or weak voice.

Consequence: Impacts communication and quality of life.

d) Psychosocial Impact:

Description: Depression, anxiety, or social withdrawal due to communication difficulties.

Consequence: May require psychological support or counseling.

e) Scar Formation:

Description: Scarring from surgical interventions may affect vocal cord function.

Consequence: Could necessitate additional treatments or surgeries.

Summary of Key Points for Vocal Cord Paralysis

Vocal cord paralysis is the loss of movement of one or both vocal cords due to nerve damage, affecting voice, breathing, and swallowing.

Symptoms include hoarseness, breathy voice, aspiration, and airway obstruction, depending on whether the paralysis is unilateral or bilateral.

Diagnosis is confirmed via **laryngoscopy**, with further investigations to identify the underlying cause.

First-line treatments include **voice therapy**, **vocal cord augmentation**, and **surgical medialization** for unilateral paralysis, and **airway management** for bilateral paralysis.

Management of underlying causes is crucial to address potential reversible factors.

Complications can be serious, including aspiration pneumonia and airway obstruction, necessitating prompt recognition and management.

Regular follow-up with ENT specialists and speech therapists is essential to monitor progress and adjust treatment plans.

Gastrointestinal

166. Gastrointestinal (GI) Bleeding

1. Detailed Definition of GI Bleeding:

Gastrointestinal (GI) bleeding refers to any form of blood loss occurring within the **gastrointestinal tract**, from the oesophagus to the rectum. It can be classified as either **upper** (above the ligament of Treitz, affecting the oesophagus, stomach, or duodenum) or **lower** (below the ligament of Treitz, affecting the small intestine, colon, rectum, or anus).

- **Upper GI bleeding (UGIB):** Includes bleeding from peptic ulcers, oesophageal varices, gastritis, and Mallory-Weiss tears.
- **Lower GI bleeding (LGIB):** Includes bleeding from diverticular disease, inflammatory bowel disease (IBD), colorectal cancer, and haemorrhoids.

2. Common Presenting Complaints and Symptoms:

Upper GI Bleeding:

- **Haematemesis:** Vomiting of fresh blood or 'coffee-ground' material.
- **Melaena:** Black, tarry stools due to digested blood from an upper GI source.
- **Epigastric pain:** Common with peptic ulcer disease.
- **Signs of hypovolaemia:** Dizziness, weakness, hypotension, and tachycardia due to blood loss.

Lower GI Bleeding:

- **Haematochezia:** Passage of fresh red blood or maroon-coloured stools, often associated with lower GI bleeding.
- **Abdominal pain:** Can indicate underlying inflammatory bowel disease, diverticulitis, or malignancy.
- **Signs of anaemia:** Pallor, fatigue, and shortness of breath due to chronic blood loss.

3. First-Line Investigations:

The primary goal in investigating GI bleeding is to assess the extent of blood loss, identify the source, and plan for appropriate management.

a) Full Blood Count (FBC):

- **Haemoglobin:** To assess for **anaemia** and gauge the severity of blood loss.
- **Platelet count:** Important in evaluating **coagulopathies** or thrombocytopenia.

b) Urea and Electrolytes (U&E):

- **Urea:** Often elevated in upper GI bleeding due to blood breakdown in the gut.
- **Creatinine:** To assess renal function, which may be compromised due to hypovolaemia.

c) Coagulation Screen:

- **Prothrombin time (PT) and International Normalised Ratio (INR):** Important in patients with underlying coagulopathies or those on anticoagulants.

d) Blood Group and Crossmatch:

- To prepare for **blood transfusion** if required.

e) Liver Function Tests (LFTs):

- Useful in identifying underlying **chronic liver disease**, which can contribute to variceal bleeding.

f) Endoscopy:

- **Upper GI endoscopy (OGD):** The **gold standard** for diagnosing and treating upper GI bleeds.
- **Colonoscopy:** Used to evaluate lower GI bleeding but is often delayed until the patient is stabilised.

g) CT Angiography:

- Can be used in cases of **ongoing lower GI bleeding** where the source is unclear and endoscopy is not possible.

4. Explanation of Investigations:

- **Haemoglobin levels:** Low haemoglobin indicates acute or chronic blood loss.
- **Urea:** Elevated urea-to-creatinine ratio is often seen in upper GI bleeding due to the absorption of blood in the gut.
- **Endoscopy:** Essential for both the **diagnosis** (identifying the source) and **management** (e.g., banding varices, clipping ulcers) of GI bleeds.

5. Diagnosis Criteria for GI Bleeding:

The diagnosis of GI bleeding is **clinical**, supported by symptoms of bleeding (e.g., **haematemesis**, **melaena**, or **haematochezia**). Diagnosis is confirmed by **endoscopic findings** in most cases. The diagnosis and severity are often classified using the following criteria:

- **Upper GI bleed:** Haematemesis, melaena, and positive findings on **endoscopy** (e.g., **ulcers**, **varices**, **erosive gastritis**).
- **Lower GI bleed:** Haematochezia and **colonoscopy** or imaging findings indicating a **colonic source** (e.g., **diverticular disease**, **angiodysplasia**, **cancer**).

6. First-Line Therapy According to Guidelines:

The management of GI bleeding focuses on **stabilisation**, **resuscitation**, and **definitive treatment**:

a) Resuscitation:

- **Airway, Breathing, and Circulation (ABC)** should be assessed immediately.
- **IV fluids** (crystalloids) should be given to stabilise hypovolaemic patients.
- **Blood transfusion:** If haemoglobin is < 7 g/dL (or < 8 g/dL in patients with cardiovascular disease).
- **Correct coagulopathies:** Administer **fresh frozen plasma (FFP)**, **vitamin K**, or **prothrombin complex concentrate (PCC)** as required.

b) Specific Treatment for Upper GI Bleeding:

- **Proton Pump Inhibitors (PPI):**
 - Used for **non-variceal upper GI bleeding** (e.g., peptic ulcers). Start with a **high-dose IV PPI infusion** (e.g., **pantoprazole 80 mg bolus**, followed by an **8 mg/hour infusion**).
- **Endoscopic Therapy:**
 - **Endoscopic variceal ligation (banding)** for **oesophageal varices**.
 - **Clipping or thermal coagulation** for bleeding **peptic ulcers**.
- **Antibiotics in Variceal Bleeding:**
 - **Ceftriaxone 1g IV daily** for 5-7 days in patients with suspected **variceal bleeding** to reduce the risk of infections such as **spontaneous bacterial peritonitis (SBP)**.
- **Terlipressin:**

- Used for **acute variceal bleeding**. Dose: **1-2 mg IV every 4-6 hours**.
- c) *Specific Treatment for Lower GI Bleeding:*
- **Colonoscopy:** Diagnostic and therapeutic, allowing for **polypectomy, diverticular clipping**, or **argon plasma coagulation** of bleeding sources.
 - **Surgery:** Required in cases of **massive lower GI bleeding** where endoscopic or radiological interventions fail.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **NSAIDs** should be avoided in patients with a history of **peptic ulcer disease** or upper GI bleeding, as they can exacerbate bleeding risk.

b) Second-Line Therapy:

- **Sengstaken-Blakemore tube:** Used in the management of **uncontrolled oesophageal variceal bleeding** when endoscopic measures fail.
- **Interventional radiology:** In cases of **persistent bleeding** unamenable to endoscopy, **embolisation** or **angiography** can be employed.
- **Surgical intervention:** For persistent bleeding despite endoscopic and radiological measures, or if haemodynamic stability cannot be achieved.

8. Routine Monitoring and Follow-Up:

1. Haemoglobin Levels:

- Regular monitoring to assess the response to resuscitation and blood transfusion.

2. Vital Signs:

- Continuous monitoring of blood pressure, heart rate, and oxygen saturation to assess for ongoing bleeding and stability.

3. Repeat Endoscopy/Colonoscopy:

- May be needed to reassess the bleeding source if the initial intervention fails or if bleeding recurs.

4. Liver Function Tests:

- Particularly important in patients with **variceal bleeding**, as **cirrhosis** is a common underlying cause.

5. Coagulation Profile:

- Regular checks in patients with underlying **coagulopathies** or on **anticoagulants**.

9. Complications:

a) Acute Complications:

- **Hypovolaemic shock:** Due to massive blood loss, leading to end-organ damage.
- **Renal failure:** From **hypoperfusion** and volume loss.
- **Cardiac complications:** Such as **myocardial ischaemia** due to reduced oxygen delivery in the context of anaemia.

b) Long-Term Complications:

- **Recurrent bleeding:** Particularly in patients with **peptic ulcers, varices**, or **malignancies**.
- **Chronic anaemia:** Due to ongoing occult blood loss, especially in **lower GI causes** like cancer or IBD.

Summary of Key Points for Gastrointestinal Bleeding:

- **GI bleeding** is classified as **upper** or **lower** based on the site of origin. Common causes of **upper GI bleeding** include **peptic ulcers** and **varices**, while **lower GI bleeding** is often due to **diverticular disease, IBD**, or **colorectal cancer**.

- Symptoms include **haematemesis**, **melaena**, and **haematochezia**, with associated signs of **hypovolaemia**.

167. Colorectal Tumours

1. Detailed Definition of Colorectal Tumours:

Colorectal tumours refer to abnormal growths that develop in the **colon** or **rectum**. These can be **benign** (e.g., polyps) or **malignant** (e.g., colorectal carcinoma). **Colorectal cancer (CRC)** is the most common malignant tumour of the large bowel, and it arises from the **epithelial lining** of the colon or rectum, often progressing from adenomatous polyps over several years. It is one of the leading causes of cancer-related deaths worldwide, with **adenocarcinoma** being the most common histological type.

2. Common Presenting Complaints and Symptoms:

The symptoms of colorectal tumours depend on the **location** of the tumour (right-sided colon, left-sided colon, or rectum) and the **extent of the disease**:

a) Right-Sided Colon Tumours (proximal colon):

- **Iron deficiency anaemia** (fatigue, pallor): Caused by chronic, occult blood loss.
- **Weight loss.**
- **Abdominal pain:** Often vague or generalised.
- **Palpable mass:** In some cases, a mass may be felt in the right lower quadrant.

b) Left-Sided Colon Tumours (distal colon):

- **Change in bowel habits:** Alternating constipation and diarrhoea.
- **Rectal bleeding:** Fresh blood in stools.
- **Tenesmus:** Feeling of incomplete evacuation.
- **Colicky abdominal pain.**
- **Bowel obstruction:** Can occur in advanced cases due to the narrowing of the bowel lumen.

c) Rectal Tumours:

- **Rectal bleeding:** Blood mixed with stool.
- **Tenesmus** and **urgency.**
- **Palpable mass** on digital rectal examination (DRE).

3. First-Line Investigations:

Initial investigations aim to diagnose the tumour, assess the stage of the disease, and determine any complications. The following are key investigations:

a) Full Blood Count (FBC):

- **Iron deficiency anaemia:** Indicates chronic blood loss, commonly associated with right-sided tumours.

b) Faecal Immunochemical Test (FIT):

- A non-invasive test to detect occult blood in the stool, used as part of screening for colorectal cancer.

c) Colonoscopy:

- **Gold standard** for diagnosis. Allows direct visualisation of the colon and rectum and enables biopsy of suspicious lesions for histological examination.

d) CT Colonography (Virtual Colonoscopy):

- Alternative for patients unable to undergo a conventional colonoscopy, providing a detailed view of the colon and rectum.

e) Carcinoembryonic Antigen (CEA):

- A **tumour marker** used in the monitoring of colorectal cancer. Elevated levels can suggest malignancy, although not specific for screening.

f) Staging CT Scan (Chest, Abdomen, Pelvis):

- Performed to assess for **metastases** to the liver, lungs, and regional lymph nodes.

g) MRI of the Pelvis:

- Essential for staging **rectal cancer** to evaluate the extent of local invasion and plan for surgical resection.

4. Explanation of Investigations:

- **Colonoscopy:** Essential for **visualisation** and **biopsy** of the tumour. It provides the most definitive diagnosis of colorectal cancer.
- **CEA:** Used in the **monitoring** of disease progression or recurrence rather than for initial diagnosis.
- **CT scans:** Used for **staging** the tumour, particularly to detect **liver** and **lung metastases**.
- **Faecal Immunochemical Test (FIT):** A useful **screening tool** in asymptomatic individuals to detect **occult blood**.

5. Diagnosis Criteria for Colorectal Tumours:

The diagnosis of colorectal tumours is confirmed through **histological examination** of biopsy samples obtained via colonoscopy. Colorectal cancer is staged using the **TNM classification**:

- **T (Tumour):** Depth of tumour invasion into the bowel wall.
- **N (Nodes):** Involvement of regional lymph nodes.
- **M (Metastasis):** Presence of distant metastases.

Dukes' classification is also used for colorectal cancer staging:

- **Dukes A:** Tumour confined to the mucosa.
- **Dukes B:** Tumour invades through the muscle layer.
- **Dukes C:** Involvement of lymph nodes.
- **Dukes D:** Distant metastasis present.

6. First-Line Therapy According to Guidelines:

The management of colorectal tumours, particularly colorectal cancer, is determined by the stage of the disease. Treatment usually involves a combination of **surgery, chemotherapy, and radiotherapy**.

a) Surgical Management:

- **Curative Surgery:**
 - **Right hemicolectomy** for right-sided tumours.
 - **Left hemicolectomy** for left-sided tumours.
 - **Sigmoid colectomy** or **anterior resection** for sigmoid and rectal tumours.
 - **Total mesorectal excision (TME)** for rectal cancer to remove the tumour and surrounding lymph nodes.
- **Palliative Surgery:** For advanced disease, surgery may be performed to relieve **obstruction** or control bleeding.

b) Chemotherapy:

- **Adjuvant chemotherapy** is often used in **stage III** or **high-risk stage II** colorectal cancer to reduce the risk of recurrence.
 - **FOLFOX regimen:** A combination of **5-fluorouracil (5-FU)**, **leucovorin**, and **oxaliplatin** is commonly used.
- **Neoadjuvant chemotherapy:** Used before surgery in **locally advanced rectal cancer** to shrink the tumour.

c) Radiotherapy:

- **Neoadjuvant radiotherapy** is often used in **rectal cancer** to reduce tumour size before surgery and improve local control.

- **Palliative radiotherapy:** Can be used to control pain, bleeding, or obstruction in advanced disease.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Surgery** may be contraindicated in patients with significant **comorbidities** or **advanced metastatic disease**.

b) Second-Line Therapy:

- **Targeted therapy** with drugs such as **bevacizumab** (anti-VEGF) and **cetuximab** (anti-EGFR) may be used in patients with **metastatic colorectal cancer**, depending on **mutational status** (e.g., **KRAS** mutation status).
- **Immunotherapy:** For selected patients with **microsatellite instability-high (MSI-H)** or **mismatch repair-deficient (dMMR)** tumours, **immune checkpoint inhibitors** like **pembrolizumab** may be an option.

8. Routine Monitoring and Follow-Up:

1. CEA Levels:

- Regular monitoring to detect **recurrence** or **metastasis** after treatment.

2. Colonoscopy:

- Follow-up colonoscopy is recommended **1 year post-surgery**, and then every **3-5 years** to detect recurrence or new polyps.

3. CT Scans:

- **CT chest/abdomen/pelvis** is performed every **6-12 months** for the first 3 years post-surgery to assess for **metastasis**.

4. Liver Function Tests:

- Important for detecting **liver metastases**.

9. Complications:

a) Surgical Complications:

- **Anastomotic leak:** A serious complication following resection.
- **Bowel obstruction:** Due to postoperative adhesions or recurrent tumour.

b) Chemotherapy Complications:

- **Neutropenia, mucositis, diarrhoea, and neuropathy** (especially with oxaliplatin).

c) Metastatic Spread:

- The most common sites of metastasis for colorectal cancer are the **liver** and **lungs**.

Summary of Key Points for Colorectal Tumours:

- **Colorectal cancer** is the most common malignancy of the large bowel, often presenting with **anaemia, change in bowel habits, and rectal bleeding**.
- **Colonoscopy** is the **gold standard** for diagnosis and allows for biopsy and removal of polyps.
- Management is primarily **surgical**, with **adjuvant chemotherapy** used in advanced cases. **Radiotherapy** is often used in **rectal cancer**.
- **Follow-up** involves regular monitoring of **CEA levels, colonoscopy, and CT imaging** to detect recurrence and metastasis.

168. Inflammatory Bowel Disease (IBD)

1. Detailed Definition of Inflammatory Bowel Disease:

Inflammatory Bowel Disease (IBD) refers to two chronic inflammatory conditions affecting the gastrointestinal tract: **Crohn's disease** and **Ulcerative colitis (UC)**. Both conditions are characterised by **inflammation of the gut**, but they differ in their **distribution** and **depth of**

involvement. IBD is thought to be caused by a combination of **genetic, immune, and environmental factors.**

- **Crohn's disease:** A **transmural** (full-thickness) inflammation that can affect any part of the GI tract from **mouth to anus**, but most commonly involves the **terminal ileum** and **colon**.
- **Ulcerative colitis:** An inflammation limited to the **mucosa** and **submucosa** of the **colon** and **rectum**, typically starting at the rectum and extending proximally in a **continuous fashion**.

2. Common Presenting Complaints and Symptoms:

a) Crohn's Disease:

- **Diarrhoea:** Typically non-bloody, intermittent.
- **Abdominal pain:** Often **colicky** and commonly located in the **right lower quadrant** (ileum involvement).
- **Weight loss:** Due to malabsorption.
- **Fatigue.**
- **Perianal disease:** Includes **anal fistulae, fissures, and abscesses.**
- **Mouth ulcers:** Aphthous ulcers.
- **Extraintestinal manifestations:** May include **arthritis, uveitis, erythema nodosum, and pyoderma gangrenosum.**

b) Ulcerative Colitis:

- **Bloody diarrhoea:** Often with **mucus.**
- **Urgency and tenesmus:** Common with rectal involvement.
- **Abdominal pain:** Typically **lower left quadrant** or **suprapubic.**
- **Fatigue.**
- **Weight loss** in more severe cases.
- **Extraintestinal manifestations:** Similar to Crohn's disease, including **arthritis, primary sclerosing cholangitis (PSC), and erythema nodosum.**

3. First-Line Investigations:

a) Blood Tests:

- **Full Blood Count (FBC):** May reveal **anaemia** due to chronic blood loss and **inflammation.**
- **C-reactive protein (CRP):** Elevated in active inflammation, used to monitor disease activity.
- **Erythrocyte sedimentation rate (ESR):** Also elevated in active inflammation.
- **Liver function tests (LFTs):** To assess for complications such as **primary sclerosing cholangitis.**
- **Iron studies, Vitamin B12, and Folate:** To assess for deficiencies due to malabsorption (particularly in **Crohn's disease**).

b) Stool Tests:

- **Faecal calprotectin:** A sensitive marker for **intestinal inflammation.** Elevated levels suggest IBD but do not distinguish between Crohn's disease and ulcerative colitis.
- **Stool culture:** To rule out infectious causes of diarrhoea (e.g., **Clostridioides difficile, Salmonella, Campylobacter**).

c) Endoscopy:

- **Colonoscopy with biopsy:**
 - **Crohn's disease:** Patchy, **cobblestone** appearance with **skip lesions.** Biopsies show **transmural inflammation** and **granulomas.**
 - **Ulcerative colitis:** Continuous **mucosal inflammation**, starting at the rectum. Biopsies show **mucosal and submucosal inflammation** with **crypt abscesses.**

d) *Imaging:*

- **MRI small bowel or CT enterography:** Useful for assessing **Crohn's disease** and detecting **fistulas, strictures, and abscesses**.
- **Abdominal X-ray:** May show signs of **toxic megacolon** in **severe ulcerative colitis**.

4. Explanation of Investigations:

- **Faecal calprotectin:** Elevated levels indicate **intestinal inflammation**, often used to distinguish IBD from irritable bowel syndrome (IBS).
- **Colonoscopy:** Essential for **visualising the colon**, obtaining **biopsies**, and differentiating between Crohn's disease and ulcerative colitis.
- **CRP and ESR:** Indicators of systemic inflammation and used to monitor **disease activity** and **flare-ups**.

5. Diagnosis Criteria for IBD:

The diagnosis of IBD is based on a combination of **clinical symptoms, endoscopic findings, histopathology, and radiological imaging**.

a) *Crohn's Disease:*

- **Endoscopic findings:** **Skip lesions, cobblestone mucosa, fissures, and fistulas**.
- **Histopathology:** **Transmural inflammation, granulomas**.
- **Imaging:** **Strictures, fistulas, or small bowel involvement**.

b) *Ulcerative Colitis:*

- **Endoscopic findings:** **Continuous inflammation** starting from the **rectum, ulcerations, friability**.
- **Histopathology:** **Mucosal and submucosal inflammation, crypt abscesses**.

6. First-Line Therapy According to Guidelines:

Treatment of IBD focuses on **inducing remission** during flares and **maintaining remission** to prevent relapses.

a) *Induction of Remission:*

- **Mild-to-Moderate Crohn's Disease:**
 - **Budesonide:** 9 mg/day for **terminal ileal or right-sided colonic disease**.
 - **Oral prednisolone:** 40 mg/day with gradual tapering over weeks for more extensive disease.
- **Mild-to-Moderate Ulcerative Colitis:**
 - **5-aminosalicylic acid (5-ASA) agents:**
 - **Mesalazine** oral or rectal formulations for **proctitis** or **left-sided colitis**.
 - **Topical corticosteroids** for rectal disease.
- **Moderate-to-Severe Disease:**
 - **IV corticosteroids:** **Hydrocortisone 100 mg IV 6-hourly** for severe flares.
 - **Biologics:** Anti-TNF agents such as **infliximab** or **adalimumab** for severe disease or when corticosteroids fail.

b) *Maintenance of Remission:*

- **Crohn's Disease:**
 - **Azathioprine** or **mercaptopurine:** Immunosuppressants used for long-term maintenance.
 - **Methotrexate:** Another option for patients intolerant of azathioprine.
 - **Biologic agents:** Continued use of **infliximab** or **adalimumab** if effective during induction.
- **Ulcerative Colitis:**
 - **Mesalazine:** Continued long-term as the first-line maintenance therapy.

- **Azathioprine** or **mercaptopurine**: Used in patients who fail 5-ASA or those requiring corticosteroids.
- **Biologics**: Anti-TNF therapy for patients with severe or refractory disease.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Corticosteroids** should be used cautiously in patients with **osteoporosis**, **diabetes**, or **hypertension** due to their systemic side effects.
- **Azathioprine** and **mercaptopurine** should be avoided in patients with **TPMT deficiency** due to the risk of myelosuppression.

b) Second-Line Therapy:

- **Biologics** (e.g., **ustekinumab**, **vedolizumab**) are second-line options for patients who do not respond to conventional therapies or anti-TNF agents.
- **Surgery**: In **Crohn's disease**, surgery may be required for **strictures**, **fistulas**, or **abscesses**. In **ulcerative colitis**, **total colectomy** may be curative in severe, refractory disease.

8. Routine Monitoring and Follow-Up:

1. Blood Tests:

- Regular monitoring of **FBC**, **LFTs**, **CRP**, and **electrolytes** to assess for **disease activity** and **drug toxicity** (e.g., **azathioprine** and **methotrexate**).

2. Faecal Calprotectin:

- Monitored to assess **ongoing inflammation** and **risk of relapse**.

3. Endoscopic Surveillance:

- Regular **colonoscopy** every 1-2 years for patients with long-standing **ulcerative colitis** or **Crohn's colitis**, as they are at increased risk of **colorectal cancer**.

4. Bone Density Monitoring:

- For patients on long-term corticosteroids due to the risk of **osteoporosis**.

9. Complications of Inflammatory Bowel Disease (IBD):

a) Crohn's Disease:

- **Fistulas**: Abnormal connections between the bowel and other organs (e.g., bowel-bladder fistulas, bowel-skin fistulas).
- **Strictures**: Narrowing of the bowel, leading to bowel obstruction.
- **Abscesses**: Intra-abdominal or perianal abscess formation due to severe inflammation.
- **Malnutrition**: Due to malabsorption, particularly in patients with small bowel involvement.
- **Increased risk of colon cancer**: Especially in patients with long-standing Crohn's colitis.
- **Growth retardation in children**: Due to malnutrition and chronic inflammation.

b) Ulcerative Colitis:

- **Toxic megacolon**: Severe colonic distension, which can be life-threatening.
- **Colorectal cancer**: Increased risk with long-standing disease, especially in patients with pancolitis (involvement of the entire colon).
- **Primary sclerosing cholangitis (PSC)**: A chronic liver disease that can occur in patients with ulcerative colitis, leading to liver cirrhosis.

c) General IBD Complications:

- **Extraintestinal manifestations**: These include **arthritis**, **uveitis**, **erythema nodosum**, **pyoderma gangrenosum**, and **hepatic disorders** such as **PSC**.
- **Anaemia**: Can occur due to chronic blood loss, malabsorption of iron, or vitamin B12 deficiency (especially in Crohn's disease).

Summary of Key Points for Inflammatory Bowel Disease (IBD):

- **Inflammatory Bowel Disease (IBD)** includes **Crohn's disease** and **ulcerative colitis**, both characterised by chronic inflammation of the gastrointestinal tract.
- Symptoms of **Crohn's disease** include **abdominal pain**, **non-bloody diarrhoea**, and **weight loss**, while **ulcerative colitis** typically presents with **bloody diarrhoea** and **rectal urgency**.
- Diagnosis is confirmed via **endoscopy with biopsy**, and **faecal calprotectin** can help differentiate IBD from irritable bowel syndrome (IBS).
- Management includes **induction of remission** with **corticosteroids** or **biologics** and **maintenance therapy** with **mesalazine**, **azathioprine**, or **biologics**.
- **Surgery** may be required in severe or refractory cases, particularly in **ulcerative colitis**, where **colectomy** can be curative.
- Regular **monitoring** is essential, including **blood tests**, **endoscopy**, and **faecal calprotectin** to manage disease activity and complications.
- Patients with long-standing IBD are at increased risk of **colorectal cancer** and require regular **colonoscopy surveillance**.

169. Diverticular Disease: Comprehensive Revision Notes

1. Detailed Definition of Diverticular Disease:

Diverticular disease refers to the presence of **diverticula**—small pouches or sacs that protrude from the wall of the colon. These pouches are formed through the weakening of the colonic wall, often due to increased intraluminal pressure.

- **Diverticulosis:** Refers to the presence of diverticula without associated inflammation or symptoms.
- **Diverticular disease:** When diverticula cause symptoms such as pain or altered bowel habits.
- **Diverticulitis:** When diverticula become inflamed or infected, leading to more severe symptoms like pain and fever.

2. Common Presenting Complaints and Symptoms:

a) Diverticulosis:

- **Often asymptomatic:** Most individuals with diverticulosis are unaware of the condition.
- **Chronic bloating, cramping, or altered bowel habits:** Constipation or diarrhoea.

b) Diverticular Disease:

- **Intermittent lower abdominal pain:** Commonly in the **left lower quadrant** (sigmoid colon involvement).
- **Bloating and flatulence.**
- **Change in bowel habits:** Alternating constipation and diarrhoea.

c) Diverticulitis:

- **Severe abdominal pain:** Usually in the **left lower quadrant**.
- **Fever, nausea, and vomiting.**
- **Tenderness on palpation:** Suggesting inflammation.
- **Rectal bleeding:** Can occur, though less common than in diverticulosis.
- **Complications:** Abscess, perforation, fistula formation, and bowel obstruction in severe cases.

3. First-Line Investigations:

a) Blood Tests:

- **Full Blood Count (FBC):** To detect **leukocytosis**, which indicates infection or inflammation in diverticulitis.

- **C-reactive protein (CRP):** Elevated in the presence of inflammation, used to gauge the severity of diverticulitis.
- **Urea and Electrolytes (U&E):** To assess renal function and check for dehydration or electrolyte imbalances.

b) Imaging:

- **CT Abdomen and Pelvis:** **Gold standard** for diagnosing **acute diverticulitis**, particularly when there are concerns about complications like perforation or abscess formation. The scan will show inflamed diverticula, bowel wall thickening, and pericolic fat stranding.
- **Abdominal X-ray:** May show signs of **bowel obstruction** or **free air** in cases of perforation.

c) Colonoscopy:

- Useful in **diverticular disease** to confirm the diagnosis and assess the extent of diverticula. However, it is **contraindicated** during **acute diverticulitis** due to the risk of perforation.

d) Stool Testing:

- **Faecal calprotectin:** Can be elevated in diverticular disease, but this is more commonly used to differentiate between inflammatory bowel disease (IBD) and functional bowel disorders.

4. Explanation of Investigations:

- **CT scan:** Provides a clear image of the colon, showing inflammation, abscess formation, or free air if perforation has occurred.
- **Colonoscopy:** Helpful for assessing chronic diverticular disease and excluding malignancy or polyps but **deferred** during acute inflammation to avoid complications.

5. Diagnosis Criteria for Diverticular Disease:

The diagnosis of diverticular disease depends on a combination of **clinical presentation**, **imaging findings**, and **colonoscopy** in chronic cases.

- **Diverticulosis:** Often found incidentally on **colonoscopy** or **CT scan**, showing multiple diverticula without inflammation.
- **Diverticular disease:** Diagnosed based on **symptoms** such as abdominal pain and altered bowel habits, often confirmed with **colonoscopy**.
- **Diverticulitis:** Confirmed by a **CT scan** showing diverticula, bowel wall thickening, and signs of inflammation or complications like an abscess.

6. First-Line Therapy According to Guidelines:

Management depends on the severity of the disease.

a) Diverticulosis and Mild Diverticular Disease:

- **Dietary fibre:** Increase intake of **high-fibre foods** (e.g., fruits, vegetables, whole grains) or use of **fibre supplements** like **ispaghula husk** to prevent constipation and reduce intraluminal pressure.
- **Adequate hydration.**
- **Analgesia:** Simple analgesics like **paracetamol** can be used for pain relief. **NSAIDs** should be avoided as they can increase the risk of perforation or worsen symptoms.

b) Acute Diverticulitis:

- **Mild cases (outpatient management):**
 - **Oral antibiotics:** Typically **co-amoxiclav** or **ciprofloxacin** with **metronidazole** for 7-10 days.
 - **Analgesia:** Use **paracetamol** or **codeine** for pain. Avoid NSAIDs due to the risk of complications.

- **Diet:** Initial **clear liquid diet**, advancing to a low-fibre diet as symptoms improve, then returning to a high-fibre diet after recovery.
- **Severe cases (hospital management):**
 - **Intravenous fluids:** For rehydration, especially in cases with vomiting or severe dehydration.
 - **Intravenous antibiotics:** Typically **piperacillin/tazobactam** or **cefuroxime** with **metronidazole**.
 - **Surgery:** May be required if there is **perforation, abscess, fistula, or severe obstruction**. Emergency **Hartmann's procedure** (resection of the diseased colon with colostomy) is common in severe cases of perforation or abscess.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **NSAIDs** should be avoided in patients with diverticulitis as they increase the risk of perforation.
- **Colonoscopy** is contraindicated during an acute episode of diverticulitis due to the risk of perforation.

b) Second-Line Therapy:

- **Percutaneous drainage:** For patients with **large abscesses** (>3 cm), percutaneous drainage may be required if they do not respond to antibiotics.
- **Surgery:** If conservative measures fail, surgery may be indicated for recurrent or complicated diverticulitis. **Elective surgery** may be considered for patients with multiple episodes of diverticulitis.

8. Routine Monitoring and Follow-Up:

1. Blood Tests:

- Monitor **CRP** and **FBC** in the acute setting to assess for resolution of inflammation and infection.

2. Imaging:

- **CT scans** may be repeated in severe cases to monitor for complications such as abscesses or fistulas.

3. Colonoscopy:

- After the resolution of acute diverticulitis, a **follow-up colonoscopy** is recommended to exclude **colorectal cancer** or other pathologies.

9. Complications of Diverticular Disease:

a) Diverticulitis Complications:

- **Abscess formation:** Localised infection, often requiring drainage.
- **Perforation:** Leads to peritonitis, a surgical emergency.
- **Fistula formation:** Abnormal connections between the bowel and other organs (e.g., bowel-bladder fistula).
- **Bowel obstruction:** Can occur due to strictures or narrowing from chronic inflammation.
- **Haemorrhage:** Diverticular bleeding can result in significant rectal bleeding, particularly from diverticulosis.

b) Diverticular Disease Complications:

- **Chronic pain:** Some patients may continue to have intermittent abdominal pain even after acute episodes have resolved.
- **Recurrent diverticulitis:** Increases the risk of complications and may eventually require surgical intervention.

Summary of Key Points for Diverticular Disease:

- **Diverticular disease** encompasses both **asymptomatic diverticulosis** and **symptomatic diverticulitis**.
- **Diverticulitis** presents with **left lower quadrant pain**, fever, and possibly rectal bleeding.
- **CT scan** is the **gold standard** for diagnosing acute diverticulitis, especially for identifying complications like abscess or perforation.
- First-line treatment includes **antibiotics**, **fluids**, and **analgesia**, with surgery reserved for complicated cases.
- **High-fibre diet** is essential for preventing diverticulosis progression and avoiding recurrent diverticulitis.

170. Malabsorption

1. Detailed Definition of Malabsorption:

Malabsorption refers to a condition in which the small intestine is unable to absorb nutrients properly from ingested food, leading to deficiencies in essential nutrients, vitamins, and minerals. Malabsorption can affect the absorption of **macronutrients** (proteins, carbohydrates, fats) or **micronutrients** (vitamins, minerals), or both. It can result from various disorders affecting **digestion**, **absorption**, or **transport** of nutrients.

Some common causes include **coeliac disease**, **chronic pancreatitis**, **lactose intolerance**, **Crohn's disease**, **small bowel bacterial overgrowth**, and **short bowel syndrome**.

2. Common Presenting Complaints and Symptoms:

Patients with malabsorption may present with a variety of symptoms depending on the underlying cause and the nutrients affected:

- **Diarrhoea**: Often chronic and steatorrhoea (pale, bulky, and foul-smelling stools due to fat malabsorption).
- **Weight loss**: Despite normal or increased appetite.
- **Bloating and abdominal discomfort**.
- **Nutritional deficiencies**: Specific symptoms may arise due to deficiencies of particular nutrients:
 - **Iron deficiency anaemia**: Fatigue, pallor.
 - **Vitamin B12 deficiency**: Fatigue, neuropathy (numbness, tingling in extremities), glossitis.
 - **Folate deficiency**: Fatigue, glossitis.
 - **Calcium/vitamin D deficiency**: Bone pain, fractures, osteomalacia, or rickets.
 - **Protein deficiency**: Muscle wasting, oedema.

3. First-Line Investigations:

a) Blood Tests:

- **Full Blood Count (FBC)**: To check for **anaemia** (iron, folate, or vitamin B12 deficiency).
- **Iron studies**: Assess for iron deficiency.
- **Vitamin B12 and Folate**: Important in evaluating the cause of anaemia.
- **Electrolytes: Calcium, magnesium, and phosphate** levels to assess for mineral deficiencies.
- **Liver function tests (LFTs)**: May be abnormal in certain conditions (e.g., coeliac disease) affecting bile salt absorption.
- **Prothrombin time (PT)**: To assess for **vitamin K deficiency**.

b) Stool Tests:

- **Faecal fat analysis**: Increased faecal fat confirms **fat malabsorption** (steatorrhoea), typically seen in **chronic pancreatitis** or **coeliac disease**.
- **Faecal elastase**: To check for pancreatic insufficiency (low in chronic pancreatitis).

- **Stool cultures:** To exclude infections or small intestinal bacterial overgrowth (SIBO).

c) Imaging:

- **Abdominal ultrasound:** To assess for structural abnormalities like **chronic pancreatitis** or **gallstones**.
- **CT scan or MRI:** Can be useful for evaluating structural causes, including **pancreatic abnormalities** or **small bowel disease**.

d) Specific Investigations:

- **Coeliac serology:** Testing for **anti-tissue transglutaminase (tTG) antibodies** or **anti-endomysial antibodies (EMA)** to diagnose **coeliac disease**.
- **Small bowel biopsy:** Via **endoscopy** to confirm **coeliac disease** or to evaluate for other causes of small bowel malabsorption (e.g., Crohn's disease).

4. Explanation of Investigations:

- **Faecal fat analysis:** Detects unabsorbed fat in the stool, confirming **steatorrhoea**. This is particularly elevated in conditions such as **coeliac disease**, **chronic pancreatitis**, and **small bowel disease**.
- **Coeliac serology:** Anti-tTG and EMA are highly sensitive and specific for diagnosing **coeliac disease**.
- **Faecal elastase:** A measure of **pancreatic exocrine function**. Low levels suggest **pancreatic insufficiency**, a common cause of malabsorption.

5. Diagnosis Criteria for Malabsorption:

The diagnosis of malabsorption depends on clinical features (e.g., **chronic diarrhoea**, **steatorrhoea**, **weight loss**, and **nutritional deficiencies**) combined with investigation results:

- **Coeliac disease:** Confirmed by **positive coeliac serology** (anti-tTG antibodies) and **villous atrophy** on **small bowel biopsy**.
- **Pancreatic insufficiency:** Suggested by **low faecal elastase** and confirmed by imaging showing features of **chronic pancreatitis**.
- **Small bowel bacterial overgrowth (SIBO):** Diagnosed through **hydrogen breath testing** or **small bowel aspirate** cultures.
- **Lactose intolerance:** Diagnosed with a **lactose breath test**.

6. First-Line Therapy According to Guidelines:

Management of malabsorption depends on the underlying cause and focuses on correcting nutrient deficiencies and treating the primary condition.

a) Nutritional Support:

- **Dietary modification:** Tailored to the underlying cause. For example, patients with **coeliac disease** require a strict **gluten-free diet**.
- **Pancreatic enzyme replacement:** For patients with **chronic pancreatitis** or pancreatic insufficiency, **pancreatic enzyme supplements** (e.g., **creon**) are given with meals.
- **Vitamin and mineral supplementation:** Replacement of **iron**, **vitamin B12**, **folate**, **vitamin D**, **calcium**, and **magnesium** as needed.

b) Treatment of Underlying Cause:

- **Coeliac disease:** Strict **lifelong gluten-free diet**.
- **Chronic pancreatitis:** **Pancreatic enzyme replacement** and managing complications like pain and diabetes.
- **SIBO:** Treated with a course of **antibiotics** (e.g., **rifaximin**, **metronidazole**).

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- Patients with **coeliac disease** must strictly avoid **gluten**, even in small amounts.

- Avoid **high-fat diets** in patients with **pancreatic insufficiency** unless pancreatic enzyme replacement is used.

b) Second-Line Therapy:

- **Immunosuppressive therapy** (e.g., **azathioprine**, **methotrexate**) may be used in **Crohn's disease** when conventional treatment fails.
- **Biologic agents** (e.g., **infliximab**, **adalimumab**) for moderate-to-severe Crohn's disease with malabsorption.
- **Surgical interventions:** May be needed in **Crohn's disease** or **short bowel syndrome** to manage severe complications such as strictures or fistulas.

8. Routine Monitoring and Follow-Up:

1. **Blood Tests:**
 - Regular monitoring of **vitamin levels** (e.g., vitamin B12, folate, vitamin D) and **iron levels** to detect and treat deficiencies early.
 - **Liver function tests** and **bone profile** to assess complications related to malnutrition (e.g., **osteomalacia**, **osteoporosis**).
2. **Repeat Endoscopy/Biopsy:**
 - **Coeliac disease:** Periodic assessment of symptoms and monitoring of **anti-tTG levels** to ensure compliance with a gluten-free diet.
3. **Nutritional Status:**
 - Ongoing evaluation of **weight**, **BMI**, and **nutritional intake** to ensure optimal recovery and prevent malnutrition.

9. Complications of Malabsorption:

a) Nutritional Deficiencies:

- **Iron deficiency anaemia:** Fatigue, pallor, weakness.
- **Vitamin B12 deficiency:** Neuropathy, cognitive disturbances.
- **Calcium/vitamin D deficiency:** Osteomalacia, fractures, and osteoporosis.
- **Protein deficiency:** Oedema, muscle wasting.

b) Specific Complications by Cause:

- **Coeliac disease:** Increased risk of **small bowel lymphoma**, **osteoporosis**, and **infertility** if untreated.
- **Chronic pancreatitis:** May lead to **diabetes mellitus** (due to destruction of pancreatic islet cells) and **chronic pain**.
- **SIBO:** Can cause severe **diarrhoea**, **vitamin deficiencies**, and **weight loss**.

Summary of Key Points for Malabsorption:

- **Malabsorption** is caused by a failure of the small intestine to absorb nutrients and can lead to **diarrhoea**, **weight loss**, and **nutritional deficiencies**.
- **Common causes** include **coeliac disease**, **chronic pancreatitis**, **Crohn's disease**, and **lactose intolerance**.
- Investigations include **faecal fat analysis**, **blood tests** for nutrient deficiencies, and **endoscopy** with biopsies.
- Treatment involves managing the **underlying cause**, replacing **deficient nutrients**, and modifying the **diet** (e.g., gluten-free diet for coeliac disease).
- Regular **monitoring** is necessary to ensure adequate nutrition and prevent complications such as **osteoporosis**, **anaemia**, and **neuropathy**.

171. Coeliac Disease

1. Detailed Definition of Coeliac Disease:

Coeliac disease is a chronic autoimmune disorder of the small intestine triggered by the ingestion of **gluten** (a protein found in wheat, barley, and rye) in genetically predisposed

individuals. In coeliac disease, gluten ingestion leads to an abnormal immune response that results in **inflammation** and **atrophy of the small intestinal villi**, leading to **malabsorption** of nutrients.

2. Common Presenting Complaints and Symptoms:

The clinical presentation of coeliac disease can vary widely, from **asymptomatic** cases to severe malabsorption. Symptoms may include:

a) Gastrointestinal Symptoms:

- **Chronic diarrhoea:** Often greasy, foul-smelling, and pale (steatorrhoea).
- **Abdominal pain and bloating.**
- **Flatulence.**
- **Weight loss:** Despite adequate food intake.

b) Non-Gastrointestinal Symptoms:

- **Iron deficiency anaemia:** Presenting with **fatigue, pallor, and lethargy** due to malabsorption of iron.
- **Folate or vitamin B12 deficiency:** Leading to **fatigue, neuropathy, and glossitis.**
- **Osteomalacia or osteoporosis:** Due to **calcium** and **vitamin D** malabsorption.
- **Dermatitis herpetiformis:** An intensely itchy skin rash, often found on the elbows, knees, buttocks, and scalp. This is a specific manifestation of coeliac disease.

c) Associated Conditions:

- **Infertility.**
- **Delayed puberty or growth failure** in children.
- **Aphthous mouth ulcers.**

3. First-Line Investigations:

The investigation of suspected coeliac disease includes serological tests and confirmatory biopsy.

a) Blood Tests:

- **Coeliac serology:**
 - **Anti-tissue transglutaminase (anti-tTG) antibodies:** The most sensitive test, especially **IgA anti-tTG**, is the first-line screening test.
 - **Anti-endomysial antibodies (EMA):** Highly specific for coeliac disease.
 - **Total IgA levels:** To rule out IgA deficiency, as this can cause false-negative anti-tTG results.
- **Full Blood Count (FBC):** To check for **anaemia** (iron, folate, or vitamin B12 deficiency).
- **Iron studies:** To assess for iron deficiency anaemia.
- **Vitamin B12 and Folate:** To assess for macrocytic anaemia.
- **Calcium and Vitamin D:** To check for deficiencies associated with malabsorption.

b) Endoscopy and Biopsy:

- **Upper GI endoscopy with small bowel biopsy:** The **gold standard** for diagnosing coeliac disease. Biopsy is taken from the **duodenum** or **jejunum** and shows characteristic changes:
 - **Villous atrophy.**
 - **Crypt hyperplasia.**
 - **Intraepithelial lymphocytosis.**

c) Faecal Tests:

- **Faecal fat test:** May be elevated, indicating **steatorrhoea** due to fat malabsorption.

4. Explanation of Investigations:

- **Anti-tTG antibodies:** The most **sensitive** serological marker for coeliac disease. Positive results strongly suggest the presence of coeliac disease, but a **biopsy** is required to confirm the diagnosis.
- **Duodenal biopsy:** The **gold standard** for diagnosis, showing **villous atrophy**, which confirms the presence of coeliac disease.
- **Iron studies** and **vitamin B12/folate** tests: To assess for nutritional deficiencies caused by malabsorption in coeliac disease.

5. Diagnosis Criteria for Coeliac Disease:

The diagnosis of coeliac disease is based on **positive serology** and **confirmatory biopsy** of the small intestine:

- **Positive anti-tTG antibodies** or **anti-EMA** antibodies.
- **Villous atrophy** and **crypt hyperplasia** on **small bowel biopsy**.

In cases where patients are unable or unwilling to undergo a biopsy, **genetic testing** for **HLA-DQ2** or **HLA-DQ8** can support the diagnosis, as nearly all patients with coeliac disease carry one or both of these alleles.

6. First-Line Therapy According to Guidelines:

The mainstay of treatment for coeliac disease is **lifelong adherence to a strict gluten-free diet**, which leads to the resolution of symptoms, normalisation of serology, and healing of the intestinal mucosa.

a) *Gluten-Free Diet:*

- Patients must avoid all sources of **gluten**, including foods containing **wheat, barley, and rye**. Processed foods should be checked for hidden sources of gluten.
- **Oats** are generally safe for most people but should be introduced cautiously, as some patients may also react to **avenin**, a protein found in oats.
- Referral to a **dietitian** is essential to educate the patient on maintaining a **gluten-free diet** and ensuring proper nutritional intake.

b) *Nutritional Supplementation:*

- **Iron supplementation:** For patients with iron deficiency anaemia.
- **Folic acid and vitamin B12:** To correct deficiencies, especially in the early stages of treatment.
- **Calcium and vitamin D:** Supplements may be necessary in patients with osteoporosis or osteomalacia.

7. Common Contraindications and Second-Line Therapy:

a) *Contraindications:*

- **Gluten** in any form must be avoided entirely to prevent symptom recurrence and long-term complications.

b) *Second-Line Therapy:*

- In cases where symptoms persist despite adherence to a gluten-free diet, **refractory coeliac disease** should be considered. **Immunosuppressive therapy** with corticosteroids (e.g., **prednisolone**) or immunomodulators (e.g., **azathioprine**) may be necessary.
- **Biologic agents** (e.g., **infliximab**) are rarely used but may be considered in **refractory or complicated coeliac disease**.

8. Routine Monitoring and Follow-Up:

1. **Coeliac Serology:**

- **Anti-tTG levels** should be monitored to assess compliance with the gluten-free diet. These antibodies typically normalise within **6-12 months** of strict adherence.
- 2. **Nutritional Status:**
 - Regular monitoring of **FBC, iron studies, vitamin B12, folate,** and **calcium/vitamin D** is essential to ensure adequate nutrition and resolution of deficiencies.
- 3. **Bone Health:**
 - Patients with long-standing coeliac disease or significant malabsorption should undergo a **DEXA scan** to assess for **osteoporosis**.
- 4. **Small Bowel Biopsy:**
 - Repeat biopsies are not routinely required if the patient is asymptomatic and compliant with the gluten-free diet, but they may be indicated in refractory cases.

9. Complications of Coeliac Disease:

a) Long-Term Complications:

- **Nutritional deficiencies:** Persistent malabsorption may result in **iron deficiency anaemia, osteoporosis, or B12 deficiency**.
- **Osteoporosis:** Due to chronic **vitamin D** and **calcium** malabsorption.
- **Infertility:** Particularly in untreated cases.
- **Dermatitis herpetiformis:** A skin manifestation of coeliac disease.
- **Small bowel lymphoma:** Patients with coeliac disease, particularly those who do not adhere to a gluten-free diet, are at increased risk of developing **enteropathy-associated T-cell lymphoma (EATL)**.

b) Refractory Coeliac Disease:

- **Refractory coeliac disease** is when symptoms persist or recur despite strict adherence to a gluten-free diet. This can lead to more severe complications like **small bowel lymphoma**. It requires further evaluation and possible **immunosuppressive therapy**.

Summary of Key Points for Coeliac Disease:

- **Coeliac disease** is an autoimmune disorder triggered by **gluten**, leading to **villous atrophy** and **malabsorption**.
- It presents with **diarrhoea, weight loss,** and **nutritional deficiencies** like **iron deficiency anaemia** and **osteoporosis**.
- **Anti-tTG antibodies** and **small bowel biopsy** are the key diagnostic tools.
- The cornerstone of management is a **lifelong gluten-free diet**.
- Regular **monitoring** for **nutritional deficiencies, bone health,** and **serology** is essential to ensure good long-term outcomes.
- **Complications** include **osteoporosis, small bowel lymphoma,** and **refractory coeliac disease**.

172. Helicobacter pylori

1. Detailed Definition of Helicobacter pylori:

Helicobacter pylori (H. pylori) is a **gram-negative, spiral-shaped bacterium** that colonises the **stomach lining** and is associated with various gastrointestinal conditions, including **gastritis, peptic ulcer disease,** and **gastric cancer**. *H. pylori* can survive in the highly acidic environment of the stomach by producing **urease**, which neutralises gastric acid and allows the bacteria to thrive in the mucosal lining.

2. Common Presenting Complaints and Symptoms:

Infection with *H. pylori* can be **asymptomatic**, but when symptomatic, it can lead to a variety of gastrointestinal issues:

a) *Dyspepsia (Indigestion)*:

- **Epigastric pain** or discomfort.
- **Bloating, belching, and early satiety.**
- **Nausea and vomiting.**

b) *Peptic Ulcer Disease*:

- **Gastric ulcers**: Epigastric pain that worsens with eating.
- **Duodenal ulcers**: Pain that improves with eating but worsens a few hours after meals.
- **Bleeding**: In severe cases, peptic ulcers may lead to **haematemesis** (vomiting blood) or **melaena** (black, tarry stools).

c) *Gastric Cancer*:

- **Unexplained weight loss.**
- **Persistent epigastric pain.**
- **Anaemia.**
- **Loss of appetite** and early satiety.

3. First-Line Investigations:

The diagnosis of *H. pylori* infection is made through a combination of **non-invasive** and **invasive tests**.

a) *Non-Invasive Tests*:

- **Urea breath test**: The patient ingests urea labelled with carbon-13 or carbon-14. *H. pylori* produces urease, which breaks down the urea, releasing labelled carbon dioxide, which can then be measured in the breath. This is the preferred non-invasive test in the UK for **active *H. pylori* infection**.
- **Stool antigen test**: Detects *H. pylori* antigens in stool samples. This test can be used both for initial diagnosis and to confirm eradication after treatment.
- **Serology**: Measures antibodies against *H. pylori*, but is not commonly used as it cannot distinguish between active and past infection.

b) *Invasive Tests*:

- **Endoscopy with biopsy**: Used in patients with more concerning symptoms, such as **weight loss, anaemia**, or those at risk of gastric cancer.
 - **Rapid urease test (CLO test)**: A biopsy is taken from the stomach during endoscopy and tested for urease activity. A colour change in the test indicates the presence of *H. pylori*.
 - **Histology**: The biopsy can also be examined under a microscope to confirm the presence of *H. pylori* and to assess for gastritis or malignancy.

4. Explanation of Investigations:

- **Urea breath test**: Detects the activity of **urease**, an enzyme produced by *H. pylori* to neutralise stomach acid. It is highly sensitive and specific for **active infection**.
- **Stool antigen test**: Detects ***H. pylori* antigens** in faeces and is used for both diagnosis and confirmation of eradication post-treatment.
- **Endoscopy with biopsy**: Allows for **direct visualisation** of the stomach lining, and biopsies can confirm infection, assess for ulcers, and rule out **gastric cancer**.

5. Diagnosis Criteria for *H. pylori*:

The diagnosis of *H. pylori* infection is based on the **presence of the bacterium** in the stomach, confirmed through one of the following tests:

- **Positive urea breath test.**

- **Positive stool antigen test.**
- **Positive rapid urease test** (from biopsy during endoscopy).
- **Histological identification** of *H. pylori* in biopsy specimens.

6. First-Line Therapy According to Guidelines:

The first-line treatment for *H. pylori* infection is **eradication therapy**, which involves a combination of **antibiotics** and **proton pump inhibitors (PPIs)**. The choice of antibiotics depends on local resistance patterns.

a) Triple Therapy (First-Line in the UK):

- **Proton pump inhibitor (PPI): Omeprazole 20-40 mg or lansoprazole 30 mg** twice daily for 7-14 days.
- **Clarithromycin 500 mg** twice daily for 7-14 days.
- **Amoxicillin 1 g** twice daily for 7-14 days.

If the patient is allergic to penicillin:

- **Metronidazole 400 mg** twice daily is used instead of amoxicillin.

b) Quadruple Therapy (If Initial Treatment Fails):

- **PPI** as above.
- **Bismuth subsalicylate 120 mg** four times daily.
- **Metronidazole 400 mg** three times daily.
- **Tetracycline 500 mg** four times daily.

Quadruple therapy is often used as **second-line therapy** in cases of treatment failure or resistance to clarithromycin.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Penicillin allergy:** **Amoxicillin** should be replaced with **metronidazole** in patients who are allergic to penicillin.
- **Metronidazole:** Should not be used with alcohol due to the risk of a **disulfiram-like reaction**.

b) Second-Line Therapy:

- If **triple therapy** fails, the patient should be treated with **quadruple therapy** or **sequential therapy** (a combination of different antibiotics given sequentially).
- **Antibiotic resistance testing:** In cases of multiple treatment failures, **antibiotic sensitivity testing** may be indicated to guide treatment.

8. Routine Monitoring and Follow-Up:

1. Test for eradication:

- Performed **at least 4 weeks** after the completion of treatment using either a **urea breath test** or **stool antigen test**. Testing should not be done sooner, as results can be affected by the use of PPIs and antibiotics.

2. Endoscopy:

- **Repeat endoscopy** is indicated if the patient had complications such as **peptic ulcer disease, gastric cancer, or refractory symptoms**.

3. Symptom monitoring:

- Patients should be monitored for the recurrence of symptoms, especially if they had peptic ulcers or gastritis.

9. Complications of *H. pylori* Infection:

a) Peptic Ulcer Disease:

- **Gastric and duodenal ulcers:** *H. pylori* is a major cause of peptic ulcer disease and can lead to complications such as **bleeding, perforation, and gastric outlet obstruction**.

b) Gastric Cancer:

- Long-standing *H. pylori* infection is associated with an increased risk of **gastric adenocarcinoma** and **gastric MALT lymphoma** (mucosa-associated lymphoid tissue lymphoma).

c) Chronic Gastritis:

- Chronic inflammation of the stomach lining can lead to **atrophic gastritis** and **intestinal metaplasia**, which are precursors to gastric cancer.

d) Iron Deficiency Anaemia:

- *H. pylori* infection can lead to **iron deficiency** due to chronic blood loss from ulcers and impaired iron absorption.

Summary of Key Points for *Helicobacter pylori*:

- ***H. pylori*** is a common **gram-negative bacterium** that causes **gastritis**, **peptic ulcer disease**, and is a risk factor for **gastric cancer**.
- Patients may present with **dyspepsia**, **abdominal pain**, or signs of **ulcer complications** such as **bleeding** or **perforation**.
- **Urea breath test** and **stool antigen test** are the main diagnostic tools for detecting **active infection**.
- First-line treatment is **triple therapy** with a **PPI**, **amoxicillin**, and **clarithromycin** for 7-14 days.
- Follow-up testing after treatment is crucial to ensure **eradication** and prevent complications such as **gastric cancer** and **MALT lymphoma**.

173. Infectious Colitis

1. Detailed Definition of Infectious Colitis:

Infectious colitis is inflammation of the colon caused by a **bacterial, viral, parasitic, or fungal** infection. It leads to **diarrhoea**, **abdominal pain**, and other gastrointestinal symptoms. Infectious colitis is often self-limiting but can be severe in some cases, leading to dehydration, electrolyte imbalances, and in rare cases, sepsis.

2. Common Presenting Complaints and Symptoms:

The presentation of infectious colitis can vary depending on the causative organism, but common symptoms include:

- **Diarrhoea:** Can range from mild to severe, often **bloody** in bacterial infections (e.g., **Shigella**, **Campylobacter**, **E. coli**).
- **Abdominal pain:** Typically **cramping** or **colicky** in nature.
- **Fever:** A common feature in bacterial colitis.
- **Nausea** and **vomiting**.
- **Dehydration:** Due to severe diarrhoea and vomiting.
- **Tenesmus:** Feeling of incomplete evacuation after defecation.
- **Rectal bleeding:** Can occur in more severe cases or in infections involving **Shigella** or **Entamoeba histolytica**.

3. First-Line Investigations:

a) Stool Tests:

- **Stool culture:** To identify the **bacterial pathogen** (e.g., **Salmonella**, **Shigella**, **Campylobacter**, **Clostridioides difficile**).
- **Stool microscopy:** To detect **parasites** such as **Entamoeba histolytica** or **Giardia lamblia**.

- **Clostridioides difficile toxin:** In patients who have received recent antibiotics or who are hospitalised, test for **C. difficile toxin** (especially in cases of **antibiotic-associated diarrhoea**).

b) Blood Tests:

- **Full Blood Count (FBC):** May show **leukocytosis** in bacterial infections or severe inflammation.
- **C-reactive protein (CRP):** Elevated in cases of severe inflammation or infection.
- **Urea and Electrolytes (U&E):** To check for **dehydration** and **electrolyte imbalances** due to diarrhoea and vomiting.

c) Imaging:

- **Abdominal X-ray or CT scan:** Typically used in severe cases to rule out complications like **toxic megacolon** or **bowel perforation**.

d) Endoscopy (If Indicated):

- **Flexible sigmoidoscopy or colonoscopy:** Rarely required in acute cases but may be considered in chronic or recurrent infections to rule out other causes like **inflammatory bowel disease (IBD)**.

4. Explanation of Investigations:

- **Stool culture:** Identifies the specific **bacterial organism** causing the infection, allowing for targeted antibiotic therapy.
- **C. difficile toxin:** Detects the presence of **C. difficile toxin**, which is important in patients with recent antibiotic use or hospitalisation, as **C. difficile** can lead to pseudomembranous colitis.
- **Stool microscopy:** Helps to identify **parasites**, such as **Entamoeba histolytica**, which can cause amoebic dysentery.

5. Diagnosis Criteria for Infectious Colitis:

The diagnosis of infectious colitis is made based on:

- **Clinical symptoms:** Diarrhoea, abdominal pain, fever, and possible rectal bleeding.
- **Positive stool culture or positive stool microscopy** for parasites.
- **Positive C. difficile toxin** test in suspected cases of antibiotic-associated diarrhoea.

6. First-Line Therapy According to Guidelines:

The treatment of infectious colitis depends on the causative organism:

a) Bacterial Colitis:

- **Supportive care:** Oral or IV **rehydration** is crucial to replace lost fluids and electrolytes.
- **Antibiotics:**
 - **Ciprofloxacin** 500 mg twice daily for 5-7 days for **Shigella**, **Campylobacter**, or **Salmonella** (if severe).
 - **Metronidazole** 400 mg three times daily or **vancomycin** 125 mg four times daily for 10 days in cases of **C. difficile** infection.

Note: Antibiotics should generally be avoided in **E. coli O157**

(enterohaemorrhagic E. coli), as they can increase the risk of **haemolytic uraemic syndrome (HUS)**.

b) Parasitic Colitis:

- **Metronidazole** 500 mg three times daily for 5-10 days for **Entamoeba histolytica**.
- **Tinidazole** or **nitazoxanide** may be used for **Giardia lamblia** infection.

c) Viral Colitis:

- **Supportive care:** Antiviral treatment is usually not required for viral causes of colitis, such as **norovirus** or **rotavirus**.
- **Hydration:** Oral rehydration therapy (ORT) is crucial for viral colitis.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Antibiotics:** Should be avoided in patients with **E. coli O157**

infections due to the increased risk of developing **haemolytic uraemic syndrome (HUS)**.

b) Second-Line Therapy:

- **Faecal microbiota transplantation (FMT):** May be considered in cases of **recurrent C. difficile infection**.
- **Rifaximin:** May be used as a second-line therapy for **recurrent or chronic infectious colitis**, particularly in cases of traveller's diarrhoea.

8. Routine Monitoring and Follow-Up:

1. Blood Tests:

- Regular monitoring of **electrolytes** and **renal function** in severe cases of dehydration.

2. Stool Culture:

- A repeat stool culture may be needed to confirm eradication in certain infections (e.g., **C. difficile**).

3. Symptoms:

- Close monitoring of diarrhoea and abdominal pain, as well as any signs of complications like **dehydration** or **sepsis**.

9. Complications of Infectious Colitis:

a) Dehydration:

- A common complication of severe diarrhoea, which may require **IV fluids** for rehydration.

b) Toxic Megacolon:

- Severe inflammation of the colon can lead to **toxic megacolon**, characterised by **colonic dilation** and **systemic toxicity**. This is a surgical emergency.

c) Haemolytic Uraemic Syndrome (HUS):

- A complication of **E. coli O157**

infection that leads to **acute kidney injury**, **haemolytic anaemia**, and **thrombocytopenia**.

d) Sepsis:

- Bacterial infections like **Salmonella** and **Shigella** can cause systemic infections leading to **sepsis**, especially in immunocompromised patients.

e) Chronic Diarrhoea:

- Some patients may develop **post-infectious irritable bowel syndrome (IBS)** or **chronic diarrhoea** following an episode of infectious colitis.

Summary of Key Points for Infectious Colitis:

- **Infectious colitis** refers to inflammation of the colon caused by bacterial, viral, or parasitic infections, presenting with **diarrhoea**, **abdominal pain**, and **fever**.
- Common causes include **C. difficile**, **Shigella**, **Salmonella**, **Campylobacter**, and **Entamoeba histolytica**.
- First-line investigations include **stool culture**, **stool microscopy**, and **C. difficile toxin testing**.
- Treatment is dependent on the causative organism and may include **antibiotics** (e.g., **ciprofloxacin**, **metronidazole**) or **supportive care** (rehydration and electrolyte replacement).
- Complications include **dehydration**, **toxic megacolon**, **haemolytic uraemic syndrome**, and **sepsis**.

174. Irritable Bowel Syndrome (IBS)

1. Detailed Definition of Irritable Bowel Syndrome (IBS):

Irritable bowel syndrome (IBS) is a **functional gastrointestinal disorder** characterised by recurrent **abdominal pain** associated with **changes in bowel habits** such as diarrhoea, constipation, or alternating between the two. It is a **chronic condition** with no identifiable structural cause, and symptoms are often exacerbated by stress or dietary factors. It is a diagnosis of exclusion, meaning other causes of similar symptoms must be ruled out.

2. Common Presenting Complaints and Symptoms:

Patients with IBS may present with the following symptoms, which often fluctuate over time:

- **Abdominal pain:** Typically **cramping** or **spasmodic**, often relieved by defecation.
- **Bloating:** A common and uncomfortable sensation of abdominal distension.
- **Altered bowel habits:**
 - **Diarrhoea:** Frequent, loose stools.
 - **Constipation:** Difficulty passing stools, hard stools.
 - **Mixed bowel habits:** Alternating between diarrhoea and constipation (IBS-M).
- **Mucus in stools:** Some patients report passage of mucus with stools.
- **Urgency:** Sudden need to pass stools, particularly in cases of diarrhoea-predominant IBS (IBS-D).
- **Tenesmus:** Feeling of incomplete evacuation after defecation.
- **Worsening of symptoms after eating:** Many patients report that certain foods can exacerbate their symptoms.
- **Fatigue and poor sleep:** Often associated with IBS due to chronic discomfort and pain.

3. First-Line Investigations:

IBS is a **diagnosis of exclusion**, meaning investigations are performed to rule out other potential causes of the symptoms, such as **inflammatory bowel disease (IBD)**, **coeliac disease**, and **gastrointestinal infections**.

a) Blood Tests:

- **Full Blood Count (FBC):** To exclude anaemia or underlying inflammatory conditions.
- **C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR):** To rule out inflammation, which may suggest **inflammatory bowel disease (IBD)**.
- **Coeliac serology:** Test for **anti-tissue transglutaminase (anti-tTG) antibodies** to rule out **coeliac disease**, which can present with similar symptoms to IBS.

b) Stool Tests:

- **Faecal calprotectin:** This test is useful for distinguishing IBS from **inflammatory bowel disease (IBD)**, as calprotectin is elevated in conditions with inflammation such as Crohn's disease and ulcerative colitis, but is normal in IBS.
- **Stool cultures:** To exclude bacterial infections or parasites, especially in cases with diarrhoea.

c) Additional Investigations (If Red Flags Present):

- **Flexible sigmoidoscopy or colonoscopy:** To rule out IBD or colorectal cancer in patients with alarming symptoms such as rectal bleeding, weight loss, or significant changes in bowel habits.
- **Thyroid function tests (TFTs):** To exclude hyperthyroidism (can cause diarrhoea) or hypothyroidism (can cause constipation).

4. Explanation of Investigations:

- **Faecal calprotectin:** A marker of **inflammation** in the gastrointestinal tract. Elevated levels suggest conditions like **Crohn's disease** or **ulcerative colitis**. It helps distinguish IBS (a non-inflammatory condition) from these inflammatory diseases.

- **Coeliac serology:** The presence of **anti-tTG antibodies** would suggest **coeliac disease**, which can cause similar symptoms to IBS, especially diarrhoea.

5. Diagnosis Criteria for IBS:

The **Rome IV criteria** are widely used to diagnose IBS:

- **Recurrent abdominal pain** at least 1 day per week in the last 3 months, associated with **two or more** of the following:
 1. **Related to defecation** (pain improves or worsens after bowel movement).
 2. **Change in stool frequency.**
 3. **Change in stool form** (appearance).

In addition to meeting these criteria, symptoms should have started at least **6 months** before diagnosis, and other causes of the symptoms should be excluded (e.g., **coeliac disease, IBD, infections**).

6. First-Line Therapy According to Guidelines:

Management of IBS is primarily focused on **symptom control**, as there is no cure for the condition. Treatment typically involves a combination of **dietary modifications, lifestyle changes, and pharmacological therapies.**

a) Dietary Advice:

- **Low-FODMAP diet:** Fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) can exacerbate IBS symptoms. Reducing foods high in FODMAPs (e.g., onions, garlic, beans, certain fruits) may help.
- **Avoiding trigger foods:** Identifying and avoiding specific trigger foods that worsen symptoms (e.g., caffeine, spicy foods, fatty foods, alcohol).
- **Fibre modification:** Increasing soluble fibre (e.g., oats, psyllium husk) for patients with constipation-predominant IBS (IBS-C) or reducing insoluble fibre (e.g., bran) in those with diarrhoea-predominant IBS (IBS-D).

b) Pharmacological Treatment:

- **Antispasmodics:**
 - **Mebeverine** 135 mg three times daily or **Hyoscine butylbromide (Buscopan)** 10-20 mg three times daily to relieve abdominal cramping.
- **Laxatives:** For constipation-predominant IBS (IBS-C):
 - **Polyethylene glycol (PEG)** or **ispaghula husk.**
 - Avoid stimulant laxatives like **senna.**
- **Antidiarrhoeal agents:** For diarrhoea-predominant IBS (IBS-D):
 - **Loperamide:** Start with 2 mg after each loose stool, up to a maximum of 8 mg per day.
- **Antidepressants:** Low-dose **tricyclic antidepressants (TCAs)** such as **amitriptyline** (10-30 mg at night) for patients with pain and discomfort not relieved by antispasmodics. **Selective serotonin reuptake inhibitors (SSRIs)** (e.g., **fluoxetine**) may be considered if depression is co-existing or if TCAs are not effective.

c) Psychological Therapies:

- **Cognitive-behavioural therapy (CBT):** May help patients whose symptoms are exacerbated by stress or anxiety.
- **Mindfulness and relaxation therapies:** For stress management.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Antidepressants:** TCAs may be contraindicated in patients with **cardiac conditions** or **glaucoma**. SSRIs should be used with caution in patients at risk of **gastrointestinal bleeding.**

- **Laxatives:** Avoid stimulant laxatives (e.g., senna) in long-term use due to the risk of **dependence**.

b) Second-Line Therapy:

- **Probiotics:** Some patients may benefit from daily probiotics, but the effects are individualised and may take 4 weeks to notice improvement.
- **Rifaximin:** A non-absorbable antibiotic that can be considered for **IBS-D** associated with bacterial overgrowth.
- **Linacotide:** Can be considered in **IBS-C** if other treatments fail.

8. Routine Monitoring and Follow-Up:

1. **Symptom Monitoring:**
 - Regular assessment of symptom severity and quality of life.
 - Monitor the patient's response to dietary modifications and medications.
2. **Psychological Impact:**
 - Consider regular review of mental health in patients, as IBS symptoms are closely linked to **stress** and **anxiety**.
3. **Weight Loss and Red Flags:**
 - If there are any red-flag symptoms such as **weight loss**, **rectal bleeding**, or **night-time symptoms**, further investigations are warranted to rule out organic diseases.

9. Complications of IBS:

IBS is generally considered a **benign** condition, but it can significantly impair the quality of life.

Complications include:

- **Reduced quality of life:** Persistent symptoms can lead to significant physical and emotional distress.
- **Mental health impact:** Higher rates of **anxiety** and **depression** in patients with IBS.
- **Medication side effects:** Long-term use of certain medications (e.g., laxatives, antidepressants) can lead to complications like dependency or other adverse effects.

Summary of Key Points for Irritable Bowel Syndrome (IBS):

- **IBS** is a **functional gastrointestinal disorder** characterised by **abdominal pain**, **bloating**, and **changes in bowel habits** without any identifiable structural cause.
- Diagnosis is based on **Rome IV criteria** and exclusion of other conditions like **coeliac disease** and **IBD**.

175. Functional Dyspepsia

1. Detailed Definition of Functional Dyspepsia:

Functional dyspepsia is a **chronic disorder** of sensation and movement (peristalsis) in the upper digestive tract, characterised by **epigastric pain**, **bloating**, **early satiety**, and **postprandial fullness**. Unlike other types of dyspepsia, **functional dyspepsia** does not have any identifiable structural cause on endoscopy or imaging, making it a **functional gastrointestinal disorder**.

2. Common Presenting Complaints and Symptoms:

Functional dyspepsia presents with a range of symptoms that affect the upper digestive tract:

a) Upper Abdominal Symptoms:

- **Epigastric pain:** Burning or gnawing pain, often exacerbated by eating or stress.
- **Postprandial fullness:** Feeling uncomfortably full after eating small amounts of food.
- **Early satiety:** Inability to finish a normal-sized meal due to feeling full early.
- **Bloating:** Generalised discomfort or swelling in the upper abdomen.

- **Nausea:** May be present, though vomiting is rare.

b) Symptoms Related to Eating:

- **Worsening of symptoms after meals.**
- **Belching and indigestion.**
- **Heartburn** or reflux-like symptoms in some cases.

3. First-Line Investigations:

Functional dyspepsia is a **diagnosis of exclusion**, meaning investigations are performed to rule out other structural or organic causes, such as **peptic ulcer disease, gastro-oesophageal reflux disease (GORD), gastrointestinal cancer, and gallbladder disease.**

a) Blood Tests:

- **Full Blood Count (FBC):** To check for anaemia, which could indicate bleeding from an ulcer or malignancy.
- **Liver function tests (LFTs):** To exclude hepatobiliary causes, such as gallstones or liver disease.
- **C-reactive protein (CRP) or erythrocyte sedimentation rate (ESR):** To rule out inflammation or malignancy.

b) Helicobacter pylori Testing:

- **Urea breath test or stool antigen test:** To test for **Helicobacter pylori (H. pylori)**, a common cause of upper gastrointestinal symptoms.

c) Endoscopy (Gastroscopy):

- **Upper gastrointestinal endoscopy:** Indicated if there are **red flag symptoms** (see below) to rule out structural causes such as **gastric cancer, peptic ulcers, or oesophagitis.**
 - **Biopsies** may be taken to check for **H. pylori** infection or evidence of **gastritis.**

d) Red Flag Symptoms (Requiring Immediate Endoscopy):

- **Unexplained weight loss.**
- **Dysphagia** (difficulty swallowing).
- **Persistent vomiting.**
- **Iron deficiency anaemia.**
- **GI bleeding** (melaena or haematemesis).
- **Family history of upper gastrointestinal malignancy.**

4. Explanation of Investigations:

- **Upper GI endoscopy:** The gold standard to rule out **structural abnormalities** in the stomach and oesophagus, such as ulcers or cancer.
- **H. pylori testing:** Detects **H. pylori infection**, which can cause gastritis or peptic ulcers but must be ruled out before diagnosing functional dyspepsia.

5. Diagnosis Criteria for Functional Dyspepsia:

Functional dyspepsia is diagnosed based on **Rome IV criteria**, which state the following:

- **One or more** of the following symptoms must be present for at least **3 months** with symptom onset at least **6 months** before diagnosis:
 1. **Postprandial fullness.**
 2. **Early satiety.**
 3. **Epigastric pain.**
 4. **Epigastric burning.**
- There should be **no evidence of structural disease** (including on endoscopy) to explain the symptoms.

Functional dyspepsia is often divided into two subtypes:

1. **Postprandial distress syndrome (PDS):** Predominantly characterised by **early satiety** and **postprandial fullness**.
2. **Epigastric pain syndrome (EPS):** Characterised by **epigastric pain** or **burning**.

6. First-Line Therapy According to Guidelines:

Management of functional dyspepsia is focused on **symptom relief, lifestyle modification, and dietary advice**.

a) Lifestyle and Dietary Modifications:

- **Avoid trigger foods:** Foods that can aggravate symptoms (e.g., **fatty foods, spicy foods, caffeine, alcohol, carbonated drinks**).
- **Eat smaller, more frequent meals:** Reducing the meal size may help with **postprandial fullness** and **early satiety**.
- **Weight loss:** For patients who are overweight, reducing body weight can alleviate symptoms.

b) Pharmacological Therapy:

1. **Proton pump inhibitors (PPIs):**
 - **Omeprazole 20 mg** once daily or **lansoprazole 30 mg** once daily for **4-8 weeks**.
 - Useful for patients with **epigastric pain** or **heartburn** symptoms. PPIs are effective in **acid suppression** and can help to exclude acid-related causes of dyspepsia.
2. **H. pylori eradication** (if positive):
 - **Triple therapy: PPI + clarithromycin 500 mg** twice daily + **amoxicillin 1 g** twice daily for **7-14 days**.
3. **Prokinetic agents:** For patients with **postprandial fullness** or **bloating**:
 - **Domperidone 10 mg** or **metoclopramide 10 mg** three times daily may be helpful for improving gastric motility.
4. **Antidepressants:** Low-dose **tricyclic antidepressants (TCAs)**, such as **amitriptyline 10-25 mg** at night, may be used for refractory symptoms, particularly for **epigastric pain**.

c) Psychological Therapies:

- **Cognitive-behavioural therapy (CBT):** For patients whose symptoms are linked to **stress** or **anxiety**, CBT may help reduce the impact of psychological factors on dyspepsia.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Proton pump inhibitors (PPIs):** Should be used cautiously in patients with long-term **osteoporosis** risk or **hypomagnesaemia**.
- **Prokinetic agents:** **Domperidone** and **metoclopramide** should be used with caution in older patients due to the risk of **extrapyramidal side effects** and **cardiac arrhythmias**.

b) Second-Line Therapy:

- **H2-receptor antagonists** (e.g., **ranitidine**): May be considered if PPIs are not tolerated or ineffective.
- **Buspirone:** A serotonin 5-HT_{1A} receptor agonist that may improve **gastric accommodation** and is used in some cases of functional dyspepsia.

8. Routine Monitoring and Follow-Up:

1. **Symptom Monitoring:**
 - Regular follow-up to assess **symptom control** and ensure compliance with **lifestyle changes** and **medications**.
2. **H. pylori Eradication:**

- If treated for **H. pylori**, a follow-up **urea breath test** or **stool antigen test** should be performed **4 weeks** after completing treatment to confirm eradication.

3. Review of Red Flags:

- Continuous monitoring for the development of **red flag symptoms** (e.g., weight loss, anaemia), which may necessitate further investigation.

9. Complications of Functional Dyspepsia:

Although functional dyspepsia is not life-threatening, it can significantly impact a patient's **quality of life**:

- **Chronic discomfort**: Persistent abdominal symptoms can lead to **anxiety** and **depression** in some patients.
- **Reduced quality of life**: Constant symptoms may affect daily activities, social interactions, and work.
- **Medication side effects**: Long-term use of **PPIs** or **prokinetics** may lead to side effects such as **osteoporosis**, **vitamin B12 deficiency**, and **gastrointestinal upset**.

Summary of Key Points for Functional Dyspepsia:

- **Functional dyspepsia** is a chronic condition characterised by **upper abdominal pain**, **bloating**, and **early satiety** without any identifiable structural cause.
- It is diagnosed based on **Rome IV criteria** and the exclusion of other conditions such as **peptic ulcers** and **gastro-oesophageal reflux disease (GORD)**.
- First-line treatment includes **lifestyle modifications**, **proton pump inhibitors (PPIs)**, and **prokinetic agents**.
- Long-term follow-up is important to monitor symptoms and ensure that no red flag features develop.

176. Malnutrition

1. Detailed Definition of Malnutrition:

Malnutrition refers to a state in which there is an **imbalance** between the body's nutritional requirements and the intake or absorption of nutrients. This can result in **undernutrition** (insufficient intake of calories, protein, or essential vitamins and minerals) or **overnutrition** (excessive intake, leading to conditions such as obesity). This summary focuses on **undernutrition**, which can occur due to **inadequate dietary intake**, **malabsorption**, **increased nutrient requirements**, or **increased losses**.

2. Common Presenting Complaints and Symptoms:

Malnutrition presents with a variety of **non-specific symptoms**, which may vary depending on the **severity** and **cause**. Key symptoms include:

a) General Symptoms:

- **Weight loss**: Unintentional and progressive.
- **Fatigue**: Due to reduced energy intake.
- **Muscle weakness** or **wasting**: A result of protein depletion.
- **Lethargy** and **lack of energy**.
- **Depression** and **irritability**.

b) Signs of Micronutrient Deficiencies:

- **Anaemia**: May cause **pallor**, **fatigue**, and **breathlessness** (iron, vitamin B12, or folate deficiency).
- **Dry skin**, **brittle hair**, and **hair loss**: Indicating deficiencies in **vitamin A**, **biotin**, or **essential fatty acids**.
- **Glossitis** or **angular cheilitis**: Common in vitamin B2 (riboflavin) and B12 deficiencies.
- **Peripheral oedema**: Can occur in severe protein deficiency (e.g., **kwashiorkor**).

- **Poor wound healing and frequent infections:** Reflecting deficiencies in **zinc** and **vitamin C**.

c) *Gastrointestinal Symptoms:*

- **Diarrhoea:** Due to malabsorption or chronic conditions.
- **Constipation:** Resulting from low dietary fibre intake.
- **Loss of appetite:** Common in cases of severe malnutrition or due to underlying disease processes.

3. First-Line Investigations:

The investigation of malnutrition involves both **clinical assessment** and **laboratory tests** to evaluate **nutritional status**, identify **micronutrient deficiencies**, and uncover **underlying causes**.

a) *Clinical Assessments:*

- **Body mass index (BMI):** Calculated by dividing weight (in kg) by height (in m²). A BMI of **<18.5 kg/m²** is considered underweight, and **<16 kg/m²** indicates severe malnutrition.
- **Mid-upper arm circumference (MUAC):** A quick, easy method to estimate muscle mass and fat stores.
- **Nutritional risk screening tools:**
 - **Malnutrition Universal Screening Tool (MUST):** Used widely in the UK to identify adults at risk of malnutrition. MUST considers BMI, unintentional weight loss, and acute illness.

b) *Blood Tests:*

- **Full blood count (FBC):** To check for anaemia (iron, B12, folate deficiencies) or infections.
- **Serum albumin:** Low levels indicate poor nutritional status, but also reflect **chronic illness** or **inflammation**.
- **Electrolytes:** Particularly **potassium**, **phosphate**, and **magnesium** may be deranged in malnutrition, especially after refeeding.
- **Vitamin and mineral levels:** Testing for deficiencies in **iron**, **vitamin B12**, **vitamin D**, **zinc**, **magnesium**, and **folate** may be indicated.
- **Liver function tests (LFTs):** To assess for liver involvement, as some liver diseases contribute to malnutrition.

c) *Special Tests:*

- **Coeliac serology:** For **coeliac disease**, a common cause of malabsorption leading to malnutrition.
- **Stool tests:** To evaluate for chronic diarrhoea or **steatorrhoea**, which may indicate **pancreatic insufficiency** or **small bowel malabsorption**.

4. Explanation of Investigations:

- **BMI:** A simple measure of body fat, BMI is used to categorise nutritional status. Low BMI suggests undernutrition.
- **Serum albumin:** Indicates **protein deficiency** but is also affected by inflammation and liver disease.
- **Electrolytes:** Essential in identifying **refeeding syndrome**, a life-threatening complication when malnourished patients are reintroduced to food.

5. Diagnosis Criteria for Malnutrition:

Malnutrition is diagnosed based on clinical and laboratory evidence of **insufficient nutrition** and **nutrient deficiencies**. The **MUST** tool is commonly used to screen for malnutrition:

MUST Criteria:

1. **BMI:**

- **>20 kg/m²**: Low risk.
 - **18.5–20 kg/m²**: Medium risk.
 - **<18.5 kg/m²**: High risk.
2. **Unintentional weight loss** over the past 3–6 months:
- **<5%**: Low risk.
 - **5–10%**: Medium risk.
 - **>10%**: High risk.
3. **Acute disease effect**: If the patient is acutely ill and there has been no nutritional intake for 5 days or more, this increases the risk of malnutrition.

6. First-Line Therapy According to Guidelines:

Management of malnutrition depends on the **underlying cause**, but general principles include **nutritional support** and **micronutrient repletion**.

a) Nutritional Support:

- **Oral nutritional support:**
 - **Dietary advice**: Increase **calorie** and **protein intake** through energy-dense foods.
 - **Oral nutritional supplements**: Protein, calorie, and micronutrient-rich supplements (e.g., **Ensure**, **Fortisip**).
- **Enteral feeding** (via **nasogastric tube** or **PEG tube**):
 - Indicated when patients cannot meet their nutritional needs orally.
- **Parenteral nutrition**:
 - Used when the gastrointestinal tract is non-functional (e.g., in severe **inflammatory bowel disease** or **bowel obstruction**).

b) Micronutrient Supplementation:

- **Multivitamin and mineral supplements**: Oral or IV supplements, particularly for deficiencies in **vitamin B12**, **vitamin D**, **iron**, **zinc**, **magnesium**, and **folate**.
- **Thiamine (vitamin B1)**: Supplemented in patients with severe malnutrition or chronic alcohol use to prevent **Wernicke's encephalopathy**.

c) Refeeding Syndrome:

- **Prevention**: Slow introduction of nutrients, particularly in severely malnourished patients. Close monitoring of **potassium**, **phosphate**, and **magnesium**.
- **Treatment**: Supplementation of **electrolytes** (phosphate, potassium, and magnesium) as needed, and gradual increase in caloric intake.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Parenteral nutrition**: Should be avoided in patients with a functioning gastrointestinal tract unless enteral feeding is not possible.
- **Oral nutritional supplements**: Should be used cautiously in patients with **dysphagia** or **aspiration risk**.

b) Second-Line Therapy:

- If **oral nutrition** is inadequate or not possible, move to **enteral feeding** via **nasogastric tube** or **PEG tube**.
- In cases of **severe malabsorption**, referral to a **gastroenterologist** may be necessary for further investigation and treatment.

8. Routine Monitoring and Follow-Up:

1. **Regular Weight Monitoring**:
 - Weekly or bi-weekly weight checks to assess progress.
2. **Blood Tests**:

- Regular monitoring of **electrolytes, albumin, and micronutrients** (e.g., phosphate, potassium, magnesium) during treatment.
3. **Refeeding Syndrome:**
- Close monitoring of patients at risk for refeeding syndrome with daily blood tests initially to check **electrolyte** levels.

9. Complications of Malnutrition:

- **Impaired immune function:** Leading to increased susceptibility to infections.
- **Delayed wound healing:** Poor protein intake affects tissue repair.
- **Muscle wasting:** Severe protein deficiency can lead to **sarcopenia**.
- **Anaemia:** Deficiency in **iron, B12, or folate** can lead to anaemia.
- **Osteoporosis:** Long-term vitamin D and calcium deficiency increases the risk of fractures.
- **Refeeding syndrome:** Potentially life-threatening complication of reintroducing food in severely malnourished patients, causing electrolyte imbalances (hypophosphataemia, hypokalaemia, and hypomagnesaemia).

177. Enteral and Parenteral Feeding

1. Detailed Definition of Enteral and Parenteral Feeding:

a) Enteral Feeding:

Enteral feeding refers to the **delivery of nutrients** directly into the **gastrointestinal (GI) tract**, usually via a **feeding tube**. It is indicated when patients are unable to consume enough nutrients orally but have a functioning digestive system.

Types of enteral feeding tubes include:

- **Nasogastric (NG) tube:** Inserted through the nose into the stomach.
- **Nasoduodenal (ND) or Nasojejunal (NJ) tube:** Inserted through the nose into the small intestine.
- **Percutaneous Endoscopic Gastrostomy (PEG) tube:** Inserted directly into the stomach through the abdominal wall.
- **Jejunostomy tube:** Inserted directly into the small intestine.

b) Parenteral Feeding:

Parenteral feeding (also known as **Total Parenteral Nutrition, TPN**) involves the **intravenous delivery** of nutrients, bypassing the GI tract entirely. It is indicated when the **GI tract is non-functional**, such as in severe **malabsorption, bowel obstruction**, or after certain surgeries.

Types of parenteral nutrition include:

- **Peripheral Parenteral Nutrition (PPN):** Administered via a peripheral vein, used for short-term or partial nutritional support.
- **Total Parenteral Nutrition (TPN):** Administered via a central vein (e.g., central venous catheter), used for long-term complete nutritional support.

2. Common Indications for Enteral and Parenteral Feeding:

a) Enteral Feeding:

- **Stroke:** Patients with swallowing difficulties (dysphagia).
- **Head and neck cancers:** Patients who cannot consume food orally.
- **Neurological disorders:** Such as **Parkinson's disease, motor neuron disease, or multiple sclerosis**, leading to difficulty swallowing.
- **Critically ill patients:** Who cannot meet nutritional requirements through oral intake.
- **Severe anorexia:** Where oral intake is inadequate.
- **Post-surgical feeding:** Where patients cannot resume oral feeding immediately but have a functioning GI tract.

b) Parenteral Feeding:

- **Short bowel syndrome:** When a significant portion of the small intestine is removed or non-functional.
- **Bowel obstruction:** In cases where enteral feeding is not possible.
- **Severe malabsorption:** As seen in **Crohn's disease** or after **major bowel resection**.
- **Peritonitis or ischemic bowel disease:** Conditions causing severe inflammation and dysfunction of the intestines.
- **Critical illness:** When enteral feeding is contraindicated or not feasible (e.g., in severe sepsis or multi-organ failure).

3. First-Line Investigations Before Starting Enteral or Parenteral Feeding:

Before initiating enteral or parenteral feeding, a thorough assessment is necessary to evaluate the patient's nutritional status and the best mode of feeding.

a) Clinical Assessment:

- **Nutritional risk screening:** Tools such as the **Malnutrition Universal Screening Tool (MUST)** are used to identify patients at risk of malnutrition.
- **Body weight and BMI:** To determine the degree of malnutrition or risk.
- **Dietary intake history:** To assess the adequacy of recent oral intake.

b) Blood Tests:

- **Full Blood Count (FBC):** To assess for anaemia or infection.
- **Urea and Electrolytes (U&E):** To check for electrolyte imbalances, especially potassium, sodium, and creatinine.
- **Liver function tests (LFTs):** To check for any liver abnormalities.
- **Serum albumin and prealbumin:** To evaluate protein status.
- **Glucose:** To assess baseline blood sugar levels.
- **Electrolytes:** Particularly **phosphate, potassium, and magnesium**, as patients starting feeding are at risk for **refeeding syndrome**.
- **Calcium, magnesium, and phosphate:** To assess for deficiencies, especially important before initiating **parenteral feeding**.

4. Explanation of Investigations:

- **Electrolyte monitoring:** Essential in both **enteral and parenteral feeding**, especially in malnourished patients who are at risk of **refeeding syndrome**, a condition characterised by electrolyte imbalances (particularly hypophosphatemia) upon refeeding.
- **Serum albumin:** Reflects long-term nutritional status, but may also be influenced by **acute illness or inflammation**.

5. First-Line Therapy According to Guidelines:

a) Enteral Feeding:

Enteral feeding is the preferred route of nutritional support when the GI tract is functional. The **NICE guidelines** recommend **enteral nutrition** over parenteral nutrition whenever possible.

- **Nasogastric feeding** is usually first-line for short-term feeding (< 4 weeks).
- **PEG feeding** is considered if long-term feeding is needed (> 4 weeks).
- **Nutritional content:** Tailored based on individual caloric and nutritional needs, with a focus on adequate **protein, fat, carbohydrate, vitamin, and mineral intake**.
 - **Standard enteral formulas** contain balanced nutrients.
 - **High-protein or high-calorie formulas** may be used for malnourished patients.

b) Parenteral Feeding:

Parenteral nutrition is indicated when enteral feeding is **contraindicated or impossible**. It should be administered under strict monitoring due to the risks associated with TPN.

- **Peripheral Parenteral Nutrition (PPN)** is used for short-term support.
- **Total Parenteral Nutrition (TPN)** is used for long-term or complete nutritional support, administered via a central venous catheter.
- **Nutritional content:** Parenteral nutrition formulas are tailored to the patient's needs and include **amino acids, glucose, lipids, electrolytes, trace elements, and vitamins.**

6. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **Enteral feeding** is contraindicated in cases of:
 - **Mechanical bowel obstruction.**
 - **Severe bowel ischaemia.**
 - **Bowel perforation.**
 - **Severe pancreatitis.**
- **Parenteral feeding** is contraindicated in patients with **normal gut function** where enteral feeding is possible.

b) Second-Line Therapy:

- If enteral feeding fails due to poor tolerance, **post-pyloric feeding** (via nasoduodenal or nasojejunal tube) may be considered.
- If enteral feeding is inadequate or contraindicated, **parenteral nutrition** is started, ensuring close monitoring of **blood glucose, electrolytes, and liver function.**

7. Routine Monitoring and Follow-Up:

a) Enteral Feeding Monitoring:

- **Daily weight** monitoring to assess nutritional progress.
- **Hydration status:** Monitor for signs of dehydration or overhydration.
- **Stool output:** To assess for diarrhoea or constipation, common complications of enteral feeding.
- **Tube placement:** Regular checks to ensure correct positioning of the feeding tube.
- **Serum electrolytes:** Regular monitoring of **sodium, potassium, and magnesium.**

b) Parenteral Feeding Monitoring:

- **Daily blood glucose** monitoring to prevent **hyperglycaemia** or **hypoglycaemia.**
- **Electrolytes:** Daily monitoring of **phosphate, potassium, and magnesium** to prevent or treat **refeeding syndrome.**
- **Liver function:** Weekly **LFTs** to monitor for **cholestasis** or liver injury associated with long-term TPN.
- **Catheter site monitoring:** Daily checks for signs of **infection** at the catheter insertion site.

8. Complications of Enteral and Parenteral Feeding:

a) Enteral Feeding Complications:

- **Aspiration pneumonia:** Due to reflux of feed into the lungs, particularly in patients with poor swallowing function.
- **Diarrhoea:** Common, especially with hyperosmolar formulas.
- **Constipation:** Due to insufficient fluid intake.
- **Tube dislodgement:** Especially in nasogastric feeding.
- **Electrolyte imbalances:** Especially **hyponatremia** if water intake is inadequate.

b) Parenteral Feeding Complications:

- **Infections:** Including **catheter-related bloodstream infections (CRBSI).**
- **Liver dysfunction:** **Cholestasis** and **hepatic steatosis** can occur with long-term TPN.
- **Hyperglycaemia:** Due to the high glucose content in TPN.

- **Refeeding syndrome:** Potentially fatal condition involving severe electrolyte imbalances, particularly **hypophosphataemia**.
- **Thrombosis:** Of the central venous catheter, leading to complications like **pulmonary embolism**.

178. Eating Disorders

1. Detailed Definition of Eating Disorders:

Eating disorders are a group of serious, complex psychological conditions that involve **abnormal eating behaviours** and **preoccupations with body weight, shape, and food**. The most common types of eating disorders include **anorexia nervosa**, **bulimia nervosa**, and **binge eating disorder (BED)**. These disorders can have significant physical and emotional consequences, impacting overall health, mental wellbeing, and social functioning.

2. Common Types of Eating Disorders and Symptoms:

a) *Anorexia Nervosa (AN):*

Characterised by **extreme restriction of calorie intake**, an **intense fear of gaining weight**, and a **distorted body image**.

- **Common Symptoms:**

- **Severe weight loss** or being **significantly underweight**.
- **Amenorrhoea** (loss of menstrual periods in females).
- **Bradycardia** (slow heart rate) and **hypotension**.
- **Cold intolerance, dry skin, brittle nails, and hair thinning**.
- **Hyperactivity or obsessive exercising**.
- **Fear of gaining weight** despite being underweight.
- **Preoccupation with food, dieting, and body shape**.

b) *Bulimia Nervosa (BN):*

Characterised by episodes of **binge eating** followed by **compensatory behaviours** such as **purging (vomiting, laxative use)**, **excessive exercise**, or **fasting** to prevent weight gain.

- **Common Symptoms:**

- **Binge eating** episodes with a sense of lack of control.
- **Self-induced vomiting, misuse of laxatives, or diuretics**.
- **Normal weight** or fluctuating weight (unlike the significant weight loss seen in anorexia).
- **Sore throat and dental erosion** (due to frequent vomiting).
- **Electrolyte imbalances** (e.g., hypokalaemia) leading to **muscle weakness or arrhythmias**.

c) *Binge Eating Disorder (BED):*

Characterised by recurrent episodes of **binge eating** without compensatory behaviours like purging.

- **Common Symptoms:**

- Frequent episodes of **eating large amounts of food** in a short time.
- **Feelings of shame, distress, or guilt** after binge eating.
- **Overweight or obesity** due to excessive calorie intake.
- **Lack of control** over eating habits.

3. First-Line Investigations:

Investigations are performed to assess the **physical impact** of the eating disorder and screen for **nutritional deficiencies, electrolyte imbalances**, and other complications. Key investigations include:

a) *Blood Tests:*

- **Full Blood Count (FBC):** To assess for **anaemia** and **leukopenia**, which may occur due to malnutrition.
- **Urea and Electrolytes (U&E):** To monitor **potassium**, **sodium**, and other electrolytes, particularly in patients with purging behaviour or severe restriction.
- **Liver function tests (LFTs):** Malnutrition can lead to **elevated liver enzymes**.
- **Calcium, phosphate, and magnesium:** These levels may be depleted, particularly in patients with **anorexia nervosa** or **refeeding syndrome**.
- **Blood glucose:** To check for **hypoglycaemia**.
- **Thyroid function tests (TFTs):** To rule out hypothyroidism, especially in patients with weight loss.

b) Electrocardiogram (ECG):

- To monitor for **arrhythmias**, **QT prolongation**, or **bradycardia**, especially in patients with anorexia nervosa or those at risk of **electrolyte imbalances**.

c) Bone Density Scan (DEXA):

- To assess for **osteopenia** or **osteoporosis** in patients with long-standing anorexia nervosa, as malnutrition and low oestrogen levels (in females) can lead to reduced bone density.

4. Explanation of Investigations:

- **Electrolytes (U&E):** Particularly important for assessing for **hypokalaemia**, **hyponatraemia**, or **hypophosphataemia**, which may occur in patients who purge or severely restrict their intake. **Low potassium** can lead to **life-threatening arrhythmias**.
- **Bone density scans:** Malnutrition, especially in **anorexia nervosa**, can lead to **reduced bone mass** and increase the risk of **fractures**.

5. Diagnosis Criteria for Eating Disorders:

a) Anorexia Nervosa:

- **Restrictive energy intake**, leading to **low body weight** relative to age, sex, and physical health.
- **Intense fear of gaining weight** or becoming fat, even when underweight.
- **Distorted perception of body weight** or shape, undue influence of body weight on self-evaluation, or denial of the seriousness of low body weight.

b) Bulimia Nervosa:

- **Recurrent episodes of binge eating**, characterised by eating an unusually large amount of food in a discrete period and a sense of **lack of control** during the episode.
- **Recurrent compensatory behaviours** to prevent weight gain, such as **self-induced vomiting**, **laxative misuse**, **excessive exercise**, or **fasting**.
- The binge eating and compensatory behaviours occur at least **once a week** for **3 months**.
- **Self-evaluation** is excessively influenced by body shape and weight.

c) Binge Eating Disorder:

- **Recurrent episodes of binge eating**, with associated feelings of **guilt**, **distress**, and **lack of control**.
- Binge eating episodes occur at least **once a week** for **3 months**.
- **No compensatory behaviours** (e.g., vomiting or excessive exercise) after binge eating.

6. First-Line Therapy According to Guidelines:

Treatment for eating disorders is **multidisciplinary** and involves **psychological support**, **nutritional rehabilitation**, and in some cases, **pharmacological treatment**.

a) Psychological Therapy:

- **Cognitive Behavioural Therapy (CBT):** Considered first-line for **bulimia nervosa**, **binge eating disorder**, and **anorexia nervosa**. CBT helps to modify the thoughts, behaviours, and feelings around food, weight, and body image.
- **Family-Based Therapy (FBT):** Particularly effective for adolescents with **anorexia nervosa**.
- **Interpersonal therapy (IPT):** May be helpful for **bulimia nervosa** and **binge eating disorder**.

b) Nutritional Rehabilitation:

- **Nutritional counselling:** To establish a **structured meal plan** and gradually restore normal eating patterns.
- **Inpatient treatment:** May be necessary for severely malnourished patients or those with **medical instability**, such as **bradycardia**, **electrolyte imbalances**, or **significant weight loss**.

c) Pharmacological Therapy:

- **SSRIs (Selective serotonin reuptake inhibitors):** Particularly **fluoxetine**, which is used in **bulimia nervosa** to reduce binge-purge cycles.
- **Antipsychotic medications:** Low-dose **olanzapine** may be used in **anorexia nervosa** to reduce obsessive thoughts about food and weight.
- **Topiramate** or **lisdexamfetamine:** Approved for treating **binge eating disorder** to reduce binge episodes.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

- **SSRIs:** Should be used cautiously in patients with **anorexia nervosa** as they may increase the risk of **QT prolongation** in the presence of **electrolyte imbalances**.
- **Antipsychotic medications:** Should be avoided in patients with a history of **severe cardiac disease**.

b) Second-Line Therapy:

- **Family-based therapy (FBT)** for **bulimia nervosa** if individual therapy is ineffective.
- **Hospitalisation** for nutritional stabilisation if outpatient management fails or if the patient is medically unstable.

8. Routine Monitoring and Follow-Up:

1. **Weight Monitoring:**

- Weekly weight checks in patients with **anorexia nervosa** or **severe weight loss** to track progress.

2. **Blood Tests:**

- Regular monitoring of **electrolytes**, especially in patients with **purging behaviours** or those receiving refeeding therapy.

3. **ECG Monitoring:**

- Periodic **ECG** to assess for **arrhythmias** or **QT prolongation** in patients on SSRIs or those with severe malnutrition.

4. **Bone Health:**

- **DEXA scans** to monitor for **osteoporosis** in patients with **long-term anorexia nervosa**.

9. Complications of Eating Disorders:

- **Electrolyte imbalances:** Particularly **hypokalaemia**, which can lead to **cardiac arrhythmias**.
- **Osteoporosis:** Due to prolonged malnutrition, particularly in **anorexia nervosa**.

- **Amenorrhoea:** Loss of menstrual periods in females due to malnutrition and low body fat, commonly seen in anorexia nervosa.
- **Cardiac complications:** Including **bradycardia**, **arrhythmias**, and **QT prolongation** due to malnutrition, electrolyte imbalances, and purging behaviours.
- **Gastrointestinal complications:** Such as **gastroparesis**, **constipation**, or **oesophageal damage** from repeated vomiting in bulimia nervosa.
- **Refeeding syndrome:** A potentially life-threatening condition that can occur when malnourished patients are reintroduced to nutrition, leading to rapid shifts in **electrolytes** (especially phosphate), causing complications like **arrhythmias**, **seizures**, or **heart failure**.
- **Immunosuppression:** Malnutrition weakens the immune system, making individuals more prone to **infections**.
- **Dental erosion:** Particularly seen in **bulimia nervosa** due to repeated vomiting and exposure to stomach acid.

Summary of Key Points for Eating Disorders:

- **Eating disorders** are a group of serious psychological conditions involving abnormal eating behaviours and preoccupations with body weight and food.
- The most common types are **anorexia nervosa**, **bulimia nervosa**, and **binge eating disorder**, each with distinct behaviours, such as **restriction**, **purging**, or **binge eating**.
- Diagnosis involves clinical evaluation and a range of **investigations**, including **blood tests**, **ECG**, and **bone density scans** to assess for physical complications.
- **Cognitive behavioural therapy (CBT)** and **nutritional rehabilitation** are first-line treatments, with **SSRIs** and **antipsychotics** considered in some cases.
- Regular **monitoring** of weight, electrolytes, and cardiovascular health is crucial, particularly in severe cases or during refeeding.

179. Gastric Cancer

1. Detailed Definition of Gastric Cancer:

Gastric cancer (also known as **stomach cancer**) refers to the **malignant growth of cells** originating from the lining of the stomach. It is a relatively common cancer worldwide, especially in East Asia, but its incidence has decreased in the UK over recent decades. The majority of gastric cancers are **adenocarcinomas**, which arise from the glandular cells of the stomach lining.

Gastric cancer can develop in any part of the stomach and may spread to nearby organs, lymph nodes, and distant parts of the body (metastasis), particularly the **liver**, **lungs**, and **peritoneum**.

2. Common Presenting Complaints and Symptoms:

Gastric cancer often presents late, as early-stage disease may be asymptomatic. When symptoms do occur, they may include:

Unexplained weight loss.

Persistent epigastric pain or upper abdominal discomfort.

Nausea and vomiting, sometimes with **blood** (haematemesis).

Dysphagia (difficulty swallowing), especially if the tumour is near the gastroesophageal junction.

Early satiety (feeling full after eating a small amount of food).

Melena (black tarry stools) indicating **gastrointestinal bleeding**.

Anaemia (due to chronic blood loss).

Bloating or a sensation of fullness in the upper abdomen.

Signs of **advanced disease** may include **ascites**, **palpable abdominal mass**, or **Virchow's node** (enlarged left supraclavicular lymph node).

3. First-Line Investigations:

a) Blood Tests:

Full blood count (FBC): To check for **anaemia** due to chronic blood loss.

Liver function tests (LFTs): May show abnormalities if the cancer has metastasised to the liver.

Tumour markers:

Carcinoembryonic antigen (CEA) and **CA 19-9** are sometimes elevated in gastric cancer, but these markers are not specific and are primarily used to monitor treatment response.

b) Upper Gastrointestinal Endoscopy (OGD):

Gastroscopy is the **gold standard investigation** for diagnosing gastric cancer. It allows direct visualisation of the stomach lining and the collection of **biopsies** from any suspicious lesions.

c) Imaging:

CT scan of the chest, abdomen, and pelvis: To assess the extent of the tumour and check for distant metastases (staging).

Endoscopic ultrasound (EUS): Provides detailed information on the **depth of tumour invasion** and involvement of **nearby lymph nodes**.

d) Staging:

Staging laparoscopy: May be performed to detect **peritoneal metastasis** that is not visible on imaging.

4. Explanation of Investigations:

Gastroscopy with biopsy is the primary diagnostic tool for detecting **gastric cancer**. It allows for both visualisation and histological confirmation.

CT scanning is essential for **staging** the cancer by identifying the local spread, lymph node involvement, and distant metastases, which helps determine the appropriate treatment plan.

5. Diagnosis Criteria for Gastric Cancer:

Gastric cancer is diagnosed through **histological examination** of biopsy specimens taken during **gastroscopy**. The **staging** of gastric cancer follows the **TNM classification** system, which assesses:

T: Tumour size and depth of invasion.

N: Lymph node involvement.

M: Distant metastasis.

6. First-Line Therapy According to Guidelines:

The treatment of gastric cancer depends on the **stage** of the disease, as well as the patient's overall health and fitness for surgery.

a) Early Gastric Cancer (Stage I):

Surgery is the main treatment, with the aim of **complete resection**. The preferred surgery is a **subtotal gastrectomy** (for distal tumours) or **total gastrectomy** (for proximal or large tumours), often with **D2 lymph node dissection** (removal of surrounding lymph nodes).

Endoscopic mucosal resection (EMR) or **endoscopic submucosal dissection (ESD)** may be considered in very early-stage cancers limited to the mucosa without lymph node involvement.

b) Advanced Gastric Cancer (Stages II and III):

Neoadjuvant chemotherapy (chemotherapy given before surgery) is often recommended to shrink the tumour and improve resectability.

After surgery, **adjuvant chemotherapy** (postoperative chemotherapy) may be given to reduce the risk of recurrence.

Chemoradiotherapy may be used in some cases, particularly for tumours with positive margins after resection.

c) Metastatic or Inoperable Gastric Cancer (Stage IV):

Palliative chemotherapy is the mainstay of treatment for metastatic gastric cancer.

Targeted therapies such as **trastuzumab** (for **HER2-positive** tumours) and **immune checkpoint inhibitors** like **pembrolizumab** (for **PD-L1-positive** tumours) may be used.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Surgery: Contraindicated in patients with **advanced metastasis** or those who are too frail to undergo major surgery.

Chemotherapy: Contraindicated in patients with **severe renal** or **liver dysfunction** or those with poor **performance status**.

b) Second-Line Therapy:

For patients who do not respond to first-line chemotherapy, second-line options include different chemotherapy agents or **immunotherapy** based on molecular testing (e.g., **nivolumab** for advanced gastric cancer).

Palliative care: In patients with **terminal gastric cancer**, symptom management, nutritional support, and pain relief are prioritised.

8. Routine Monitoring and Follow-Up:

Post-surgical follow-up:

Regular monitoring for **recurrence** through clinical examination and imaging, such as **CT scans** or **endoscopy**.

Nutritional support, particularly after **gastrectomy**, to monitor for **vitamin deficiencies** (e.g., **vitamin B12**, **iron**, **calcium**).

During chemotherapy:

Monitor **blood counts**, **renal** and **liver function** to assess for **chemotherapy toxicity**.

Regular imaging to assess the **response to chemotherapy**.

9. Complications of Gastric Cancer:

Metastasis: Gastric cancer commonly spreads to the **liver**, **peritoneum**, and **lymph nodes**. Metastasis to the **lungs** or **bones** may also occur.

Gastric outlet obstruction: Tumour growth can obstruct the exit of the stomach, causing **vomiting** and **malnutrition**.

Bleeding: Gastric cancer can cause **gastrointestinal bleeding**, leading to **anaemia** or acute haemorrhage.

Perforation: Advanced tumours can penetrate through the stomach wall, leading to **peritonitis**.

Summary of Key Points for Gastric Cancer:

Gastric cancer is most often diagnosed through **gastroscopy** with **biopsy**, and staging is essential for determining the appropriate treatment.

Early-stage gastric cancer is treated with **surgery** (subtotal or total gastrectomy), while **neoadjuvant chemotherapy** is often used for more advanced stages.

Metastatic gastric cancer is treated with **palliative chemotherapy** and **targeted therapies**, depending on molecular characteristics.

Follow-up includes monitoring for **recurrence** and managing complications such as **malnutrition** after gastrectomy.

180. Gastro-Oesophageal Reflux Disease (GORD) and Hiatus Hernia

1. Detailed Definition of Gastro-Oesophageal Reflux Disease (GORD):

Gastro-oesophageal reflux disease (GORD) is a chronic condition in which **stomach acid** or bile refluxes into the **oesophagus**, causing irritation and damage to the oesophageal lining. It is characterised by **heartburn** and **regurgitation**. GORD can lead to complications such as **oesophagitis**, **Barrett's oesophagus**, and even **oesophageal adenocarcinoma** in severe cases.

A **hiatus hernia** occurs when part of the stomach pushes through the **diaphragmatic hiatus** into the chest cavity. While hiatus hernias are often asymptomatic, they frequently contribute to or exacerbate GORD symptoms.

2. Common Presenting Complaints and Symptoms:

GORD Symptoms:

Heartburn: A burning sensation in the chest, usually after eating, worsened by lying down or bending over.

Regurgitation: Sour-tasting acid or food returning into the mouth.

Dysphagia: Difficulty swallowing, which may indicate oesophageal stricture or severe inflammation.

Chest pain: Sometimes mimicking angina, but related to acid reflux.

Chronic cough, hoarseness, or sore throat: These may be caused by **laryngopharyngeal reflux**.

Nocturnal symptoms: Symptoms that worsen at night due to lying flat, leading to disturbed sleep.

Hiatus Hernia Symptoms:

Often **asymptomatic**, but may contribute to or worsen GORD symptoms.

Epigastric pain or discomfort, particularly after meals.

Bloating or early satiety (feeling full after eating a small amount).

3. First-Line Investigations:

a) Clinical Assessment:

A diagnosis of GORD is often made based on **clinical symptoms**, especially if there is a clear history of **heartburn** and **regurgitation**.

b) Endoscopy (OGD):

Indicated if there are **red-flag symptoms** such as **dysphagia**, **weight loss**, **persistent vomiting**, or **suspected Barrett's oesophagus**. It can detect **oesophagitis**, **strictures**, and **hiatus hernia**.

c) 24-Hour pH Monitoring:

Measures the degree of **acid reflux** into the oesophagus. It is used to confirm the diagnosis of GORD, especially in patients with atypical symptoms or where endoscopy is normal.

d) Oesophageal Manometry:

Assesses **oesophageal motility** and **lower oesophageal sphincter (LOS) function**. It is particularly useful in patients with **dysphagia** or before considering surgery.

4. Explanation of Investigations:

Endoscopy: Visualises the **oesophageal lining** to check for inflammation (**oesophagitis**), **Barrett's oesophagus**, and other complications.

pH monitoring: Quantifies **acid reflux** episodes, confirming GORD in patients with typical and atypical symptoms.

5. Diagnosis Criteria for GORD and Hiatus Hernia:

GORD is diagnosed based on clinical symptoms, particularly **heartburn** and **regurgitation**, and may be supported by findings on **endoscopy** or **pH monitoring**.

Hiatus hernia is diagnosed on **endoscopy** or **imaging** (e.g., **barium swallow**), where the stomach is seen to protrude through the **diaphragm**.

6. First-Line Therapy According to Guidelines:

a) Lifestyle Modifications:

Weight loss: In overweight patients, weight loss can significantly reduce reflux symptoms.

Dietary changes: Avoid triggers such as **spicy foods**, **caffeine**, **chocolate**, **alcohol**, and **fatty meals**.

Meal timing: Avoid large meals and eating late at night. **Wait at least 3 hours** after eating before lying down.

Elevation of the head of the bed: Helps reduce nocturnal symptoms.

b) Pharmacological Treatment:

Proton Pump Inhibitors (PPIs):

Omeprazole (20-40 mg daily) or **Lansoprazole** (15-30 mg daily) are first-line treatments to reduce **gastric acid production**.

Mechanism of action: Inhibit the **H⁺/K⁺ ATPase** in gastric parietal cells, leading to decreased acid secretion.

Duration: Usually started as a **4-8 week course**. Long-term use may be required for **severe** or **chronic cases**.

H2 Receptor Antagonists:

Ranitidine or **famotidine** may be used if PPIs are contraindicated or not tolerated.

Mechanism of action: Block the **histamine H2 receptors** in the stomach, reducing acid production.

Antacids and Alginates:

Gaviscon or **Peptac** can provide symptomatic relief by neutralising stomach acid and forming a **protective barrier** on top of the stomach contents.

c) Surgical Treatment for Hiatus Hernia and Severe GORD:

Laparoscopic Nissen Fundoplication:

Surgical treatment of GORD and **large hiatus hernias**. The upper part of the stomach is wrapped around the lower oesophagus to **strengthen the lower oesophageal sphincter** (LOS) and prevent reflux.

Considered in patients who do not respond to medical therapy or have severe complications (e.g., **Barrett's oesophagus**, strictures).

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

PPIs: Long-term use may be associated with **osteoporosis**, **hypomagnesaemia**, and **Clostridium difficile infections**. Use with caution in patients at risk for these conditions.

Surgery: Contraindicated in patients with **severe comorbidities** or who are not fit for major surgery.

b) Second-Line Therapy:

If symptoms persist despite **PPI treatment**, consider **increasing the dose** or switching to another PPI.

Surgical treatment is considered for patients with **severe GORD** or **hiatus hernia** who fail medical therapy or cannot tolerate long-term PPIs.

8. Routine Monitoring and Follow-Up:

Response to Treatment:

Assess symptom improvement after **4-8 weeks** of PPI treatment.

Consider **endoscopy** if symptoms persist or worsen despite medical therapy.

Long-Term Monitoring:

Patients with **Barrett's oesophagus** should undergo regular **surveillance endoscopy** to monitor for **dysplasia** and early signs of cancer.

Bone Health:

For patients on long-term PPIs, consider monitoring for **osteoporosis** and checking **calcium** and **vitamin D** levels.

9. Complications of GORD and Hiatus Hernia:

Barrett's oesophagus: A condition where the normal squamous epithelium of the oesophagus is replaced by columnar epithelium. It increases the risk of **oesophageal adenocarcinoma**.

Oesophageal strictures: Narrowing of the oesophagus due to chronic inflammation, leading to **dysphagia**.

Oesophagitis: Inflammation of the oesophageal lining, which can cause **bleeding** or **ulcers**.

Aspiration pneumonia: Occurs when refluxed acid or food enters the lungs, causing infection.

Summary of Key Points for GORD and Hiatus Hernia:

GORD is characterised by **acid reflux** and **heartburn**, often associated with **hiatus hernia**.

Diagnosis is usually clinical but may require **endoscopy** or **pH monitoring** for confirmation.

First-line treatment includes **lifestyle modifications** and **PPI therapy** (e.g., omeprazole).

Surgical intervention (e.g., **Nissen fundoplication**) is considered in patients who fail medical therapy or have severe disease.

Complications include **Barrett's oesophagus**, **oesophagitis**, and **aspiration pneumonia**.

181. Peptic Ulcer Disease (PUD) and Gastritis

1. Detailed Definition of Peptic Ulcer Disease (PUD):

Peptic ulcer disease (PUD) refers to the formation of **ulcers** (open sores) in the lining of the stomach, **duodenum**, or lower oesophagus due to the corrosive action of **gastric acid** and **pepsin**. The two primary types of ulcers are:

Gastric ulcers: Occur in the stomach.

Duodenal ulcers: Occur in the first part of the small intestine (duodenum).

Gastritis refers to **inflammation** of the stomach lining, which may be acute or chronic. Unlike peptic ulcers, gastritis does not involve ulceration but can lead to erosions in severe cases.

2. Common Presenting Complaints and Symptoms:

Peptic Ulcer Disease Symptoms:

Epigastric pain: A gnawing or burning pain in the upper abdomen that may improve or worsen after eating.

Gastric ulcer pain is often **worse after eating**.

Duodenal ulcer pain is typically **relieved by eating** and may worsen several hours after a meal.

Nausea and **vomiting**.

Bloating and **belching**.

Haematemesis (vomiting blood) or **melen**a (black tarry stools) in cases of ulcer bleeding.

Weight loss: May occur in severe or chronic cases.

Gastritis Symptoms:

Epigastric discomfort or **burning**.

Nausea and **vomiting**.

Loss of appetite.

Bloating or a feeling of fullness.

In severe cases, symptoms of **upper gastrointestinal bleeding**, such as **haematemesis** or **melen**a.

3. First-Line Investigations:

a) Blood Tests:

Full blood count (FBC): To assess for **anaemia** secondary to chronic blood loss from an ulcer or gastritis.

Liver function tests (LFTs): To assess for liver-related causes of gastrointestinal symptoms.

Helicobacter pylori testing: Can be performed using:

Urea breath test.

Stool antigen test.

Serological testing (less commonly used).

b) Upper Gastrointestinal Endoscopy (OGD):

Gastroscopy is the **gold standard** for diagnosing both **PUD** and **gastritis**. It allows direct visualisation of the gastric and duodenal mucosa and the ability to take **biopsies** to confirm **Helicobacter pylori** infection or rule out malignancy.

c) Other Investigations:

Barium meal: Rarely used now, but can detect ulcers and inflammation.

Fasting serum gastrin: For patients suspected of having **Zollinger-Ellison syndrome** (a gastrin-secreting tumour).

4. Explanation of Investigations:

Upper GI endoscopy: Allows visualisation of the stomach and duodenum to identify ulcers or gastritis and take biopsies for **H. pylori** or cancer.

H. pylori testing: Detects the presence of **Helicobacter pylori**, a major cause of **PUD** and **gastritis**.

5. Diagnosis Criteria for PUD and Gastritis:

Peptic Ulcer Disease:

Gastric or duodenal ulcers identified on **endoscopy**, usually greater than **5 mm** in diameter and penetrating through the muscularis mucosae.

H. pylori infection confirmed by **urea breath test**, **stool antigen test**, or **biopsy**.

Gastritis:

Inflammation of the stomach lining seen on **endoscopy**, with or without erosion.

Diagnosis is confirmed with **biopsies** showing **inflammation**, which may be **acute** or **chronic**.

6. First-Line Therapy According to Guidelines:

a) Lifestyle Modifications:

Avoidance of irritants: Reduce the intake of **NSAIDs**, **alcohol**, **spicy foods**, and **caffeine**, all of which can exacerbate symptoms.

Smoking cessation: Smoking can delay ulcer healing and increase the risk of recurrence.

Weight loss: Recommended for overweight individuals with reflux symptoms.

b) Pharmacological Treatment:

Proton Pump Inhibitors (PPIs):

First-line therapy for both **PUD** and **gastritis**.

Examples: **Omeprazole** (20-40 mg daily) or **Lansoprazole** (15-30 mg daily).

Mechanism of action: PPIs inhibit **H⁺/K⁺ ATPase** in the gastric parietal cells, reducing gastric acid secretion, promoting ulcer healing, and reducing gastritis inflammation.

H. pylori Eradication Therapy:

For **H. pylori-positive ulcers** or gastritis, **triple therapy** is used:

PPI (e.g., omeprazole 20 mg twice daily).

Amoxicillin (1 g twice daily) and **clarithromycin** (500 mg twice daily) for 7-14 days.

If allergic to **penicillin**, **metronidazole** can be substituted for **amoxicillin**.

H2-Receptor Antagonists:

Used if PPIs are contraindicated or not tolerated.

Examples: **Ranitidine** (150 mg twice daily).

Mechanism of action: Blocks **histamine H2 receptors** in the stomach, reducing acid production.

Antacids and Alginates:

Provide **symptomatic relief** by neutralising stomach acid.

Example: **Gaviscon, Peptac**.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

PPIs: Long-term use may be associated with **osteoporosis**, **hypomagnesaemia**, and increased risk of **Clostridium difficile infection**.

H. pylori eradication therapy: Contraindicated in patients with **antibiotic allergies** (e.g., **penicillin allergy**).

b) Second-Line Therapy:

If the patient does not respond to **triple therapy**, consider **quadruple therapy**, which adds **bismuth subsalicylate** or substitutes different antibiotics based on **culture sensitivities** for **H. pylori**.

8. Routine Monitoring and Follow-Up:

Endoscopy:

Repeat **gastroscopy** after **6-8 weeks** for patients with **gastric ulcers** to ensure healing and rule out malignancy.

H. pylori Testing:

Confirm eradication with a **urea breath test** or **stool antigen test** at least 4 weeks after completion of treatment.

Long-Term PPI Use:

Monitor for complications such as **osteoporosis** or **hypomagnesaemia** in patients on long-term PPIs.

9. Complications of PUD and Gastritis:

Gastrointestinal bleeding: Ulcers can erode into blood vessels, causing **haematemesis** or **melaena**.

Perforation: Ulcers can perforate through the stomach or duodenal wall, leading to **peritonitis**.

Gastric outlet obstruction: Chronic ulcers or gastritis can cause **scarring** or **swelling**, leading to blockage of the stomach outlet.

Malignancy: Chronic **H. pylori infection** and **gastritis** can lead to **gastric cancer**.

Summary of Key Points for Peptic Ulcer Disease and Gastritis:

Peptic ulcer disease (PUD) involves the formation of ulcers in the stomach or duodenum, while **gastritis** refers to inflammation of the stomach lining.

Both conditions may present with **epigastric pain**, **nausea**, and in severe cases, **bleeding** (e.g., haematemesis, melena).

Helicobacter pylori infection is a common cause of both **PUD** and **gastritis**. **Endoscopy** and **H. pylori testing** are key investigations.

First-line treatment includes **PPIs** and **H. pylori eradication therapy** if infection is confirmed.

Complications include **bleeding**, **perforation**, and, in the case of **chronic H. pylori infection**, an increased risk of **gastric cancer**.

182. Oesophageal Cancer

1. Detailed Definition of Oesophageal Cancer:

Oesophageal cancer is a malignancy that arises in the lining of the **oesophagus**. The two main types are:

Adenocarcinoma: Typically occurs in the lower oesophagus, often linked to **Barrett's oesophagus** and **gastro-oesophageal reflux disease (GORD)**.

Squamous cell carcinoma: Usually found in the upper or mid-oesophagus and associated with **smoking**, **alcohol consumption**, and **achalasia**.

Oesophageal cancer often presents late and has a poor prognosis due to its typically advanced stage at diagnosis.

2. Common Presenting Complaints and Symptoms:

Patients with oesophageal cancer often present with the following symptoms:

Dysphagia: Progressive difficulty swallowing, first for solids and later for liquids.

Weight loss: Unintentional and significant weight loss is common.

Odynophagia: Painful swallowing, often with advanced disease.

Retrosternal pain or discomfort: Often described as a burning or aching sensation.

Hoarseness: May occur due to **involvement of the recurrent laryngeal nerve**.

Regurgitation of food or saliva, particularly in advanced disease.

Cough or aspiration: Occurs if the tumour invades the trachea.

Vomiting: Especially if there is significant obstruction.

3. First-Line Investigations:

a) Endoscopy (OGD):

Upper gastrointestinal endoscopy (OGD) is the **gold standard** investigation for diagnosing oesophageal cancer. It allows direct visualisation of the tumour and **biopsy** for histological diagnosis.

b) Imaging for Staging:

CT scan of the chest, abdomen, and pelvis: Performed to assess the **extent of the tumour**, **local invasion**, and **distant metastasis**.

Endoscopic ultrasound (EUS): Used to determine the **depth of tumour invasion** and **lymph node involvement**.

PET-CT: May be used in certain cases to assess for distant metastases.

c) Blood Tests:

Full blood count (FBC): May show **anaemia** due to chronic blood loss.

Liver function tests (LFTs): Assesses liver function, especially if **liver metastases** are suspected.

4. Explanation of Investigations:

OGD with biopsy is the primary diagnostic tool for confirming **oesophageal cancer**. Biopsies are taken to identify whether the cancer is an **adenocarcinoma** or **squamous cell carcinoma**.

CT and PET-CT scans help to stage the cancer, determining how far it has spread and whether surgery is possible.

5. Diagnosis Criteria for Oesophageal Cancer:

Oesophageal cancer is confirmed by **histological examination** of biopsies taken during an **endoscopy**. The diagnosis is classified based on:

Type of cancer: **Adenocarcinoma** or **squamous cell carcinoma**.

Staging: The **TNM staging system** is used to determine the extent of the disease:

T: Tumour size and depth of invasion.

N: Lymph node involvement.

M: Distant metastasis.

6. First-Line Therapy According to Guidelines:

a) Surgery:

Oesophagectomy is the treatment of choice for **localised oesophageal cancer** (T1-T3, N0-N1) without distant metastases.

Involves **removal of part or all of the oesophagus** and reconstruction using part of the stomach or colon.

Open or minimally invasive techniques may be used, depending on tumour location and patient fitness.

b) Neoadjuvant and Adjuvant Therapy:

Neoadjuvant chemotherapy or **chemoradiotherapy** is often given **before surgery** to shrink the tumour and improve surgical outcomes.

Adjuvant chemotherapy or **radiotherapy** may be considered after surgery, especially if there are positive lymph nodes or margins.

c) Palliative Therapy for Advanced Disease:

In patients with **inoperable or metastatic oesophageal cancer**, the main treatment goals are **symptom relief** and **palliation**:

Palliative chemotherapy or **radiotherapy** to slow tumour growth and control symptoms.

Endoscopic stent placement to relieve **dysphagia** in patients with advanced disease.

Laser therapy or **brachytherapy** may be used to reduce tumour size and improve swallowing.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Surgery is contraindicated in patients with **advanced metastases** or those who are not fit for major surgery due to severe comorbidities.

Chemotherapy may be contraindicated in patients with severe **renal** or **hepatic dysfunction**, or those with poor performance status.

b) Second-Line Therapy:

For patients with **refractory or relapsed disease** after first-line chemotherapy, second-line options include other chemotherapy agents (e.g., **taxanes**) or **immunotherapy** for selected patients with **PD-L1-positive tumours**.

8. Routine Monitoring and Follow-Up:

Post-surgical monitoring:

Regular **imaging** (CT scans) and **clinical assessments** to detect **recurrence**.

Nutritional support, especially after oesophagectomy, to ensure adequate **food intake** and monitor for **malnutrition**.

During chemotherapy or radiotherapy:

Regular monitoring of **blood counts**, **renal**, and **liver function** to assess for **treatment toxicity**.

Endoscopy may be repeated in certain cases to assess tumour response.

9. Complications of Oesophageal Cancer:

Metastasis: Oesophageal cancer can metastasise to the **lungs**, **liver**, **bones**, and **lymph nodes**.

Dysphagia and Malnutrition: Tumour growth can obstruct the oesophagus, causing severe difficulty swallowing, leading to **malnutrition** and **weight loss**.

Aspiration pneumonia: Occurs when regurgitated food or acid is inhaled into the lungs, causing infection.

Oesophageal perforation: A rare but serious complication, especially during endoscopic procedures.

Fistula formation: In advanced cases, a fistula may form between the oesophagus and the trachea, leading to recurrent chest infections and aspiration.

Summary of Key Points for Oesophageal Cancer:

Oesophageal cancer is a serious malignancy often presenting with **dysphagia**, **weight loss**, and **regurgitation**. It is most commonly diagnosed through **endoscopy with biopsy**.

Adenocarcinoma and **squamous cell carcinoma** are the two major types, with risk factors including **GORD**, **smoking**, and **alcohol consumption**.

Surgical resection (oesophagectomy) is the mainstay of treatment for early-stage disease, often preceded by **neoadjuvant chemotherapy**.

Palliative care is key in advanced cases, aiming to relieve symptoms such as **dysphagia** and improve quality of life.

Complications include **metastasis**, **dysphagia**, **malnutrition**, and **aspiration pneumonia**.

183. Achalasia

1. Detailed Definition of Achalasia:

Achalasia is a rare motility disorder of the **oesophagus** characterised by the **failure of the lower oesophageal sphincter (LOS) to relax** during swallowing and the **absence of normal peristalsis** in the oesophageal body. This results in a functional obstruction at the junction between the oesophagus and the stomach, causing difficulty in swallowing (dysphagia) and other related symptoms.

Achalasia is thought to be due to the **degeneration of the ganglion cells** in the myenteric plexus of the oesophagus, leading to impaired relaxation of the sphincter and lack of coordinated muscle contractions.

2. Common Presenting Complaints and Symptoms:

Patients with achalasia typically present with a combination of the following symptoms:

Dysphagia: Difficulty swallowing both **solids** and **liquids** (in contrast to mechanical obstructions, where liquids are initially easier to swallow).

Regurgitation: The backflow of undigested food and fluids, particularly at night.

Chest pain: A feeling of pressure or discomfort in the chest, sometimes mimicking angina.

Weight loss: Often due to difficulty eating and malnutrition.

Heartburn: Despite the absence of acid reflux, patients often report heartburn-like symptoms.

Aspiration: Especially when lying down, leading to coughing or choking.

3. First-Line Investigations:

a) Oesophageal Manometry:

Manometry is the **gold standard diagnostic test** for achalasia. It measures the pressure in the oesophagus and lower oesophageal sphincter, confirming the absence of peristalsis and the **failure of the LOS to relax**.

b) Barium Swallow:

A **barium swallow X-ray** shows characteristic findings of achalasia, including the **“bird beak” appearance**, where the lower oesophagus tapers into a narrow point before entering the stomach.

It also reveals **oesophageal dilation** due to food and fluid accumulation.

c) Upper Gastrointestinal Endoscopy (OGD):

Endoscopy is performed to rule out other causes of dysphagia, such as **oesophageal cancer** or **strictures**. While it does not diagnose achalasia, it can exclude a **malignancy** (pseudoachalasia), which may mimic the symptoms.

d) Chest X-ray:

May show a **widened mediastinum** or a **fluid level** in the oesophagus, indicating food stasis due to obstruction.

4. Explanation of Investigations:

Manometry: Measures the strength and pattern of oesophageal muscle contractions and the function of the LOS, confirming the absence of peristalsis and high-pressure LOS.

Barium swallow: Provides a visual of the oesophageal shape, confirming the **narrowing at the LOS** and **dilation** above.

Endoscopy: Ensures there is no other structural abnormality, such as **tumours** or **strictures**, contributing to the symptoms.

5. Diagnosis Criteria for Achalasia:

Achalasia is diagnosed based on a combination of:

Oesophageal manometry showing:

Incomplete relaxation of the LOS.

Absence of peristalsis in the oesophagus.

Barium swallow revealing the classic “**bird beak**” narrowing.

Exclusion of other causes via **endoscopy**.

6. First-Line Therapy According to Guidelines:

a) Lifestyle Modifications:

Dietary adjustments: Patients should eat **small, frequent meals**, avoid eating before bed, and elevate the head of the bed to reduce regurgitation.

b) Pharmacological Therapy:

Nitrates (e.g., **isosorbide dinitrate**) or **calcium channel blockers** (e.g., **nifedipine**) can reduce the pressure in the LOS, although they are generally only used for short-term relief.

Mechanism of action: Both drugs relax smooth muscle, including the LOS.

c) Endoscopic and Surgical Treatments:

Pneumatic Dilatation:

Involves **inflating a balloon** inside the lower oesophagus to stretch the LOS. This treatment is effective in many patients but may require repeated procedures.

Risk: A small risk of **oesophageal perforation** exists.

Botulinum Toxin Injection:

Botulinum toxin (Botox) is injected into the LOS to **paralyse** the sphincter muscles, reducing their pressure and allowing easier passage of food.

Mechanism of action: Botox inhibits the release of acetylcholine, reducing sphincter contraction.

Usually used in elderly or frail patients who are not candidates for surgery, but the effects are often temporary (lasting 6–12 months).

Heller’s Myotomy:

Surgical myotomy is considered the definitive treatment. In this procedure, the **muscles of the LOS** are cut to allow food to pass into the stomach.

Laparoscopic Heller's myotomy is the most common surgical approach.

It is often combined with a **partial fundoplication** (wrapping part of the stomach around the oesophagus) to reduce the risk of post-surgical **acid reflux**.

Peroral Endoscopic Myotomy (POEM):

A newer, less invasive endoscopic approach to **Heller's myotomy**.

Involves creating a tunnel in the oesophageal wall endoscopically and cutting the LOS muscles.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Surgical interventions (e.g., Heller's myotomy) are contraindicated in patients who are not fit for surgery due to severe **comorbidities**.

Pneumatic dilatation is contraindicated in patients at high risk of **oesophageal perforation**.

b) Second-Line Therapy:

In cases where **pneumatic dilatation** or **Botox injections** fail, patients may require surgical **Heller's myotomy** or **POEM**.

Botulinum toxin injections can be repeated if necessary, especially in patients unfit for surgery.

8. Routine Monitoring and Follow-Up:

Post-treatment monitoring:

Patients treated with **pneumatic dilatation** or **myotomy** should be regularly reviewed to assess for symptom recurrence.

Endoscopic surveillance may be required for patients with longstanding achalasia due to the risk of developing **oesophageal cancer**.

Monitor for complications:

Reflux symptoms post-surgery should be monitored, as **Heller's myotomy** increases the risk of **gastro-oesophageal reflux disease (GORD)**.

Periodic **endoscopic evaluation** for **Barrett's oesophagus** or other complications in long-standing achalasia cases.

9. Complications of Achalasia:

Oesophageal perforation: A risk associated with **pneumatic dilatation** and other treatments.

Gastro-oesophageal reflux: Common after **Heller's myotomy** and may lead to **Barrett's oesophagus**.

Aspiration pneumonia: Due to regurgitation of food and fluids, particularly during sleep.

Oesophageal cancer: Patients with long-standing achalasia are at increased risk of developing **oesophageal squamous cell carcinoma**.

Summary of Key Points for Achalasia:

Achalasia is characterised by **impaired relaxation of the lower oesophageal sphincter** and the **absence of oesophageal peristalsis**, causing dysphagia and regurgitation.

Oesophageal manometry is the **gold standard** diagnostic test, supported by **barium swallow** and **endoscopy**.

First-line treatments include **pneumatic dilatation**, **Botox injections**, and **Heller's myotomy**.

Patients with achalasia are at increased risk of developing **oesophageal cancer**, particularly **squamous cell carcinoma**, requiring long-term monitoring.

184. Eosinophilic Oesophagitis (EoE)

1. Detailed Definition of Eosinophilic Oesophagitis (EoE):

Eosinophilic oesophagitis (EoE) is a **chronic, immune/antigen-mediated disease** of the oesophagus characterised by **inflammation** and **eosinophil infiltration** of the oesophageal mucosa. EoE leads to symptoms of **oesophageal dysfunction**, including **dysphagia** and **food impaction**. The condition is primarily driven by **allergic responses** to food antigens and environmental allergens.

2. Common Presenting Complaints and Symptoms:

The presentation of EoE can vary depending on age but commonly includes:

Dysphagia: Difficulty swallowing, particularly with **solid foods**.

Food impaction: Food getting stuck in the oesophagus, often requiring emergency intervention.

Chest pain: Non-cardiac chest pain, which may be mistaken for **GORD**.

Heartburn: Reflux-like symptoms that are often unresponsive to proton pump inhibitors (PPIs).

Abdominal pain: Particularly in children.

Failure to thrive or poor feeding: Common presentations in children.

In chronic cases, **fibrosis** of the oesophagus can lead to **strictures** and worsening of dysphagia.

3. First-Line Investigations:

a) Upper Gastrointestinal Endoscopy (OGD):

The **gold standard** for diagnosing EoE. Endoscopy reveals **oesophageal rings, linear furrows, white plaques, or exudates**.

Biopsies from multiple areas of the oesophagus are required for histological confirmation, showing **infiltration of eosinophils** (≥ 15 eosinophils per high-power field is diagnostic).

b) Histology:

Biopsy samples are stained and examined to identify **eosinophil infiltration**. A count of ≥ 15 eosinophils per high-power field (HPF) is diagnostic.

c) pH Monitoring and Manometry:

pH monitoring may be performed to rule out **gastro-oesophageal reflux disease (GORD)**, which can mimic EoE.

Oesophageal manometry is often normal but can be useful if motility disorders are suspected.

d) Allergy Testing:

Skin prick tests and **specific IgE testing** may be used to identify potential food allergens, as many cases of EoE are linked to **food allergies** (e.g., to milk, wheat, soy, eggs, peanuts, and shellfish).

4. Explanation of Investigations:

Endoscopy with biopsy: Confirms the diagnosis by visualising eosinophil infiltration in the oesophageal mucosa. The presence of eosinophils in the oesophagus is pathognomonic for EoE.

pH monitoring: Excludes GORD, especially when symptoms overlap.

Allergy testing: Helps identify potential **dietary triggers** to guide **elimination diets**.

5. Diagnosis Criteria for Eosinophilic Oesophagitis:

The diagnosis of EoE is confirmed based on the following criteria:

Symptoms of oesophageal dysfunction, such as **dysphagia** or **food impaction**.

Histological evidence of eosinophil infiltration (≥ 15 eosinophils per high-power field) from oesophageal biopsy.

Exclusion of other causes of oesophageal eosinophilia, particularly **GORD**.

6. First-Line Therapy According to Guidelines:

a) Dietary Management:

Elimination diets: Identifying and removing potential food allergens from the diet is the first line of treatment for many patients. The most common approaches include:

6-food elimination diet: Excludes **milk, soy, eggs, wheat, peanuts/tree nuts**, and **seafood**.

Elemental diet: Consists of amino acid-based formulas, which is highly effective but difficult to maintain.

Directed elimination: Based on results from **allergy testing**.

b) Pharmacological Treatment:

Proton Pump Inhibitors (PPIs):

PPIs (e.g., **omeprazole, lansoprazole**) are often used as first-line therapy for EoE. They help reduce inflammation in some patients, even in the absence of acid reflux.

Mechanism of action: PPIs inhibit the **H⁺/K⁺ ATPase** in gastric parietal cells, reducing acid secretion and, in some cases, eosinophilic inflammation.

Topical Corticosteroids:

Swallowed topical corticosteroids (e.g., **fluticasone** or **budesonide**) are used to treat eosinophilic inflammation.

Mechanism of action: Reduces eosinophilic infiltration and inflammation in the oesophagus.

Administration: Inhalers are used, but the medication is swallowed rather than inhaled, allowing it to coat the oesophagus.

c) Endoscopic Dilatation:

Endoscopic dilatation is considered in patients with **severe strictures** or narrowing of the oesophagus. This is a mechanical solution to improve swallowing but does not treat the underlying inflammation.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Topical corticosteroids: Long-term use may lead to **oesophageal candidiasis**.

Dietary elimination: May be challenging to maintain and can lead to **nutritional deficiencies** if not properly supervised.

b) Second-Line Therapy:

Systemic corticosteroids: Reserved for severe or refractory cases but are not commonly used due to the risk of systemic side effects.

Biologic therapies: Such as **monoclonal antibodies** targeting **IL-5** or **IL-13** (key cytokines in eosinophilic activation) are under investigation but not routinely used yet.

8. Routine Monitoring and Follow-Up:

Endoscopy and Biopsies:

Regular follow-up with **repeat endoscopy** and biopsies is necessary to monitor for **eosinophilic infiltration** and assess treatment response.

Symptom Tracking:

Patients should be regularly assessed for symptoms of **dysphagia**, **food impaction**, and **weight loss**.

Dietary Monitoring:

Ensure that patients on elimination diets are maintaining adequate **nutrition** and avoiding potential allergens.

9. Complications of Eosinophilic Oesophagitis:

Oesophageal strictures: Chronic inflammation can lead to fibrosis and **narrowing** of the oesophagus, worsening dysphagia.

Food impaction: In severe cases, food can become stuck in the oesophagus, requiring **endoscopic removal**.

Perforation: Rarely, endoscopic dilatation can result in perforation of the oesophagus.

Malnutrition: Particularly in children, due to difficulty eating and restrictive diets.

Summary of Key Points for Eosinophilic Oesophagitis:

Eosinophilic oesophagitis (EoE) is a chronic inflammatory disease of the oesophagus caused by **eosinophil infiltration**, leading to **dysphagia** and **food impaction**.

Endoscopy with biopsy is the gold standard for diagnosis, with ≥ 15 eosinophils per high-power field confirming EoE.

First-line treatment includes **dietary management**, particularly **elimination diets**, and **swallowed topical corticosteroids** to reduce eosinophilic inflammation.

Complications include **oesophageal strictures**, **food impaction**, and the potential need for **endoscopic dilatation**.

Regular **endoscopic monitoring** and **allergy testing** are key to managing symptoms and preventing complications.

185. Gallstones and Biliary Colic

1. Detailed Definition of Gallstones and Biliary Colic:

Gallstones (cholelithiasis) are **solid particles** that form in the **gallbladder** from cholesterol, bile salts, and bilirubin. They can range in size from microscopic crystals to large stones and can be composed of:

Cholesterol stones: The most common type, caused by an imbalance in bile components.

Pigment stones: Formed from excess bilirubin, often related to haemolysis or liver disease.

Biliary colic is the term used to describe the **pain** that occurs when a gallstone temporarily blocks the **cystic duct**. This obstruction prevents the gallbladder from emptying properly, leading to increased pressure and pain. The term "colic" is somewhat misleading, as the pain is typically **constant** rather than intermittent.

2. Common Presenting Complaints and Symptoms:

Symptoms of gallstones and biliary colic include:

Right upper quadrant (RUQ) or epigastric pain: Often described as severe, constant pain that can last from 30 minutes to several hours. The pain may radiate to the **right shoulder** or **back**.

Pain after eating fatty foods: Often triggered by meals high in fat.

Nausea and vomiting.

Dyspepsia, bloating, and belching.

No fever or signs of systemic infection, distinguishing biliary colic from cholecystitis or cholangitis.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs): May show elevated **bilirubin**, **alkaline phosphatase (ALP)**, and **gamma-glutamyl transferase (GGT)** if there is bile duct obstruction.

Full blood count (FBC): May be normal in uncomplicated biliary colic but is useful for ruling out infection (e.g., in cholecystitis).

Amylase/lipase: Should be measured to exclude **pancreatitis** if the clinical presentation suggests it.

b) Imaging:

Ultrasound scan:

The **first-line investigation** for diagnosing **gallstones**.

High sensitivity for detecting stones in the gallbladder and may show gallbladder wall thickening or bile duct dilation.

Magnetic Resonance Cholangiopancreatography (MRCP):

Used to detect stones in the **common bile duct** (choledocholithiasis), especially when ultrasound results are unclear, or there is suspicion of bile duct obstruction.

Endoscopic Retrograde Cholangiopancreatography (ERCP):

Primarily used for **therapeutic purposes** to remove stones from the **common bile duct**. It is typically reserved for confirmed choledocholithiasis.

4. Explanation of Investigations:

Ultrasound: The primary diagnostic tool for detecting **gallstones** and assessing the **gallbladder and biliary tree**. It helps visualise stones, wall thickening, and duct dilation.

MRCP: A non-invasive imaging technique that visualises the **biliary ducts** and detects any stones or strictures in the bile ducts.

ERCP: Used for both **diagnosing** and **removing stones** in the common bile duct.

5. Diagnosis Criteria for Gallstones and Biliary Colic:

Gallstones are diagnosed based on:

Ultrasound findings of stones in the gallbladder or bile ducts.

Biliary colic is diagnosed clinically by:

Sudden onset of RUQ or epigastric pain that is usually triggered by fatty foods.

Absence of fever or systemic signs of infection.

Ultrasound confirmation of **gallstones** without evidence of gallbladder inflammation (distinguishing it from cholecystitis).

6. First-Line Therapy According to Guidelines:

a) Pain Management:

Nonsteroidal anti-inflammatory drugs (NSAIDs) (e.g., **ibuprofen, diclofenac**) are the **first-line** treatment for pain relief. NSAIDs reduce inflammation and relieve pain.

Opioid analgesics (e.g., **morphine, codeine**) may be used in severe cases, although they may increase the risk of **spasm of the sphincter of Oddi**.

b) Dietary Advice:

Patients are advised to **avoid fatty meals**, which can trigger gallbladder contraction and biliary colic.

c) Definitive Treatment:

Elective laparoscopic cholecystectomy (removal of the gallbladder) is the definitive treatment for symptomatic gallstones to prevent recurrence of biliary colic and complications such as **acute cholecystitis** or **choledocholithiasis**.

Laparoscopic cholecystectomy is preferred due to quicker recovery and less post-operative pain compared to open surgery.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Surgery may be contraindicated in patients who are **unfit for surgery** due to severe comorbidities or advanced age.

NSAIDs are contraindicated in patients with **peptic ulcer disease**, **renal impairment**, or **NSAID sensitivity**.

b) Second-Line Therapy:

In patients who cannot undergo surgery, **ursodeoxycholic acid** may be used to **dissolve cholesterol stones**, although this is generally a slow and less effective treatment.

ERCP is indicated for patients with confirmed **common bile duct stones** to both diagnose and remove the stones.

8. Routine Monitoring and Follow-Up:

Post-surgical monitoring:

After **laparoscopic cholecystectomy**, most patients do not require long-term follow-up unless there are complications.

Monitoring for complications:

In patients with gallstones who do not undergo surgery, regular monitoring for signs of complications such as **acute cholecystitis** or **cholangitis** is important.

9. Complications of Gallstones and Biliary Colic:

Acute cholecystitis: Inflammation of the gallbladder, often with fever, RUQ pain, and a positive **Murphy's sign**.

Choledocholithiasis: Gallstones that obstruct the common bile duct, leading to **jaundice** and potentially **cholangitis**.

Cholangitis: A severe infection of the biliary tree, presenting with **Charcot's triad** (fever, RUQ pain, and jaundice).

Gallstone pancreatitis: Occurs if a gallstone blocks the **pancreatic duct**, causing inflammation of the pancreas.

Gallbladder perforation: Rare but serious, leading to **peritonitis**.

Summary of Key Points for Gallstones and Biliary Colic:

Gallstones form in the gallbladder and can cause **biliary colic**, characterised by RUQ or epigastric pain, often triggered by **fatty meals**.

Ultrasound is the primary diagnostic tool for detecting gallstones.

First-line treatment includes **pain management** with **NSAIDs** and **dietary modifications**.

Laparoscopic cholecystectomy is the definitive treatment to prevent recurrent symptoms and complications.

Complications of untreated gallstones include **acute cholecystitis**, **choledocholithiasis**, and **gallstone pancreatitis**.

186. Acute Pancreatitis

1. Detailed Definition of Acute Pancreatitis:

Acute pancreatitis is a **sudden inflammation** of the pancreas that can range from mild, self-limiting symptoms to a severe, life-threatening condition. It is often triggered by the premature activation of digestive enzymes within the pancreas, leading to **pancreatic autodigestion**, inflammation, and local or systemic complications. The two most common causes of acute pancreatitis are **gallstones** and **alcohol consumption**.

2. Common Presenting Complaints and Symptoms:

Patients with acute pancreatitis typically present with:

Severe epigastric or upper abdominal pain: Often **radiating to the back**, described as a constant, dull ache. The pain is typically worsened by eating and lying supine and is partially relieved by sitting forward.

Nausea and vomiting.

Abdominal tenderness and distension.

Fever.

Tachycardia.

Hypotension: In severe cases, due to systemic inflammatory response.

Additional signs in severe cases include:

Cullen's sign: Periumbilical bruising.

Grey-Turner's sign: Flank bruising, indicating retroperitoneal haemorrhage.

3. First-Line Investigations:

a) Blood Tests:

Serum amylase or lipase:

Amylase or **lipase** levels more than three times the upper limit of normal are highly suggestive of acute pancreatitis.

Lipase is more specific for pancreatitis than amylase.

Liver function tests (LFTs): Raised **bilirubin**, **ALP**, or **ALT** may suggest **gallstone pancreatitis**.

Full blood count (FBC): Raised **white cell count** is common, indicating an inflammatory response.

Urea and electrolytes: Used to monitor **kidney function** and detect dehydration.

C-reactive protein (CRP): Elevated CRP levels are a marker of **inflammation** and may correlate with the severity of the pancreatitis.

Calcium: Hypocalcaemia can occur in severe cases.

Arterial blood gases (ABGs): To assess **oxygenation** and detect any underlying metabolic disturbances, such as **metabolic acidosis**.

b) Imaging:

Abdominal Ultrasound:

Often used first to detect **gallstones** and assess the biliary tree for obstruction, which may have caused the pancreatitis.

CT scan (contrast-enhanced):

The **gold standard** imaging modality for assessing the severity of pancreatitis and detecting complications such as **necrosis**, **pseudocysts**, or **abscesses**.

A CT scan is usually reserved for patients who have severe pancreatitis or fail to improve after 48–72 hours.

MRCP (Magnetic Resonance Cholangiopancreatography):

Used to evaluate the **biliary and pancreatic ducts** for obstruction or stones.

4. Explanation of Investigations:

Amylase/lipase: Elevated levels confirm the diagnosis of pancreatitis, with lipase being more specific.

Ultrasound: Identifies **gallstones** or biliary ductal dilatation, which are common causes of pancreatitis.

CT scan: Provides detailed imaging to assess the pancreas and surrounding organs for **complications** like necrosis or fluid collections.

5. Diagnosis Criteria for Acute Pancreatitis:

Acute pancreatitis is diagnosed if **two out of three** of the following criteria are met:

Typical abdominal pain consistent with pancreatitis (severe, epigastric, and radiating to the back).

Serum amylase or lipase greater than three times the upper limit of normal.

Characteristic findings on imaging, such as inflammation of the pancreas on **CT scan** or **ultrasound**.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

Intravenous fluid resuscitation: Aggressive IV fluids (e.g., **0.9% sodium chloride**) to prevent hypovolaemia, which is crucial in the first 24–48 hours.

Pain management: Typically with **opioids** (e.g., **morphine, pethidine**).

Nutritional support:

Early enteral feeding is recommended once the patient is stable, as it reduces the risk of infections and improves outcomes.

Nasojejunal feeding may be used if the patient cannot tolerate oral intake.

b) Antibiotics:

Routine antibiotics are not recommended unless there is evidence of **infection**, such as infected pancreatic necrosis or cholangitis.

c) Treating Underlying Cause:

Gallstone pancreatitis: If gallstones are the cause, **ERCP** may be required to remove stones from the bile duct, particularly in cases of **biliary obstruction** or cholangitis.

Cholecystectomy: Gallbladder removal (cholecystectomy) should be performed after recovery to prevent recurrence in cases of gallstone pancreatitis.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

NSAIDs may be contraindicated due to **renal impairment** or **peptic ulcer disease**, commonly exacerbated by pancreatitis.

b) Second-Line Therapy:

For patients with **severe pancreatitis**, consider admission to a **high-dependency unit (HDU)** or **intensive care unit (ICU)** for close monitoring.

Endoscopic or surgical intervention may be required for complications such as **pancreatic necrosis, pseudocysts, or abscesses**.

8. Routine Monitoring and Follow-Up:

Daily monitoring of vital signs: Including heart rate, respiratory rate, and urine output to assess for signs of worsening pancreatitis or systemic complications.

Frequent blood tests:

Monitoring **electrolytes, renal function, and blood gases** is crucial, especially in severe cases.

CRP levels can be checked serially to assess the inflammatory response and disease progression.

Imaging follow-up: Repeat imaging, such as a **CT scan**, may be required if the patient is not improving clinically after initial treatment to assess for complications like necrosis.

9. Complications of Acute Pancreatitis:

Necrotising pancreatitis: Pancreatic tissue death, which increases the risk of infection and sepsis.

Pseudocysts: Fluid collections that can develop weeks after an acute episode.

Acute respiratory distress syndrome (ARDS): Due to systemic inflammation affecting the lungs.

Renal failure: Often due to severe hypovolaemia or systemic inflammatory response.

Hypocalcaemia: Can occur in severe pancreatitis, leading to tetany or arrhythmias.

Chronic pancreatitis: Long-term inflammation and damage to the pancreas, leading to permanent scarring and digestive issues.

Pancreatic abscesses: Infected fluid collections requiring drainage.

Summary of Key Points for Acute Pancreatitis:

Acute pancreatitis is a sudden inflammation of the pancreas, commonly caused by **gallstones** or **alcohol**.

Patients present with **severe epigastric pain**, often radiating to the back, accompanied by nausea and vomiting.

Diagnosis is based on elevated **amylase or lipase** levels and imaging (ultrasound or CT).

Supportive care with **IV fluids**, **pain relief**, and **early enteral feeding** is the mainstay of treatment.

Complications include **necrosis**, **pseudocysts**, **respiratory failure**, and **renal failure**.

ERCP and **cholecystectomy** are key interventions in gallstone-induced pancreatitis to prevent recurrence.

187. Chronic pancreatitis

1. Detailed Definition of Chronic Pancreatitis:

Chronic pancreatitis is a long-term, progressive inflammatory condition of the pancreas that leads to **irreversible damage**, **fibrosis**, and loss of both exocrine and endocrine function. It is characterised by persistent inflammation, pain, and structural changes in the pancreas, including calcification and ductal irregularities. Chronic pancreatitis often results in **pancreatic insufficiency**, leading to **malabsorption**, **steatorrhoea**, and **diabetes**.

2. Common Presenting Complaints and Symptoms:

Patients with chronic pancreatitis typically present with:

Chronic abdominal pain: Persistent or recurrent **epigastric pain** that can radiate to the back. The pain may be worse after meals and can be severe and disabling.

Steatorrhoea: Fatty, oily stools due to pancreatic exocrine insufficiency, resulting in malabsorption of fats.

Weight loss: Due to malabsorption and poor dietary intake, often associated with pain after eating.

Diabetes mellitus: Late in the disease process, as the pancreas loses its endocrine function.

Nausea and vomiting: Common during episodes of exacerbation.

3. First-Line Investigations:

a) Blood Tests:

Serum amylase and lipase: These are often normal or only mildly elevated in chronic pancreatitis, in contrast to acute pancreatitis.

Liver function tests (LFTs): To assess for any associated liver or biliary tract disease.

Fasting blood glucose: To check for the development of diabetes.

Faecal elastase test: A marker of **pancreatic exocrine insufficiency**. Levels $<200 \mu\text{g/g}$ in the stool suggest pancreatic enzyme deficiency.

b) Imaging:

Abdominal Ultrasound:

May show **pancreatic calcifications**, ductal dilation, and atrophy, which are suggestive of chronic pancreatitis.

CT scan of the abdomen:

Provides a more detailed view of the **pancreas** and can show **calcifications**, ductal dilations, and structural changes.

Magnetic Resonance Cholangiopancreatography (MRCP):

A non-invasive imaging technique used to visualise the **pancreatic ducts** and detect ductal strictures, irregularities, or obstructions.

Endoscopic Ultrasound (EUS):

Can be used to assess pancreatic structure, detect small ductal changes, and obtain tissue samples if necessary.

4. Explanation of Investigations:

Faecal elastase test: Measures the levels of elastase, an enzyme produced by the pancreas. Low levels indicate **pancreatic insufficiency**.

Imaging: Both **ultrasound** and **CT** scans can reveal structural changes in the pancreas such as **calcifications**, **ductal dilation**, and **fibrosis**, which are hallmark features of chronic pancreatitis.

5. Diagnosis Criteria for Chronic Pancreatitis:

The diagnosis of chronic pancreatitis is made based on:

Clinical symptoms: Chronic or recurrent epigastric pain, steatorrhoea, and weight loss.

Imaging findings: Evidence of pancreatic calcification, ductal irregularities, or pancreatic atrophy on **CT**, **MRCP**, or **ultrasound**.

Pancreatic exocrine insufficiency: Confirmed by a **low faecal elastase** test, which indicates insufficient pancreatic enzyme production.

Impaired glucose tolerance or **diabetes:** Suggestive of **endocrine insufficiency** in the late stages of the disease.

6. First-Line Therapy According to Guidelines:

a) Pain Management:

Paracetamol or **NSAIDs** are typically first-line treatments for pain management.

Opioids: Used for more severe pain but should be prescribed cautiously due to the risk of dependency and tolerance.

Pregabalin or **gabapentin:** These can be used for neuropathic pain, which may occur due to pancreatic nerve damage.

b) Nutritional Support:

Pancreatic enzyme replacement therapy (PERT):

Patients with exocrine insufficiency should receive **pancreatic enzyme supplements** (e.g., **Creon**) with meals to aid digestion and improve nutrient absorption.

The standard starting dose is **25,000 to 40,000 units** of lipase per meal, adjusted based on response.

Vitamin supplementation: Fat-soluble vitamins (A, D, E, K) should be supplemented if malabsorption is present.

c) Management of Diabetes:

Insulin therapy: For patients who develop diabetes due to pancreatic damage (termed **Type 3c diabetes**).

d) Alcohol and Smoking Cessation:

Alcohol abstinence: Essential in all patients with chronic pancreatitis, as alcohol is a major cause and exacerbator of the condition.

Smoking cessation: Smoking is also a risk factor for the progression of chronic pancreatitis and should be strongly discouraged.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

NSAIDs may be contraindicated in patients with **peptic ulcers** or **renal impairment**.

Opioids should be used cautiously to avoid dependency and are not recommended as first-line therapy for long-term pain management.

b) Second-Line Therapy:

Endoscopic treatment: For patients with **obstructive pancreatitis** due to strictures or stones in the pancreatic duct, endoscopic techniques can be used to dilate strictures or remove stones.

Surgical options: Reserved for patients with severe, intractable pain or complications such as pancreatic ductal obstruction. Surgery may involve **pancreatic duct drainage** (e.g., **Puestow procedure**) or partial **pancreatic resection**.

8. Routine Monitoring and Follow-Up:

Regular blood tests:

Blood glucose levels should be monitored to check for the development of diabetes.

LFTs and **serum albumin** to monitor liver function and nutritional status.

Follow-up imaging:

Regular imaging may be required to monitor for complications such as **pancreatic pseudocysts**, **ductal strictures**, or **pancreatic cancer**.

Nutritional monitoring:

Regular assessment for malabsorption and nutrient deficiencies, particularly fat-soluble vitamins.

9. Complications of Chronic Pancreatitis:

Pancreatic insufficiency: Leads to malabsorption, steatorrhoea, and weight loss due to the loss of digestive enzyme production.

Diabetes mellitus: Often occurs as a result of pancreatic endocrine damage in later stages.

Pancreatic pseudocysts: Fluid-filled sacs that can develop on the pancreas, sometimes causing pain or infection.

Pancreatic cancer: Patients with chronic pancreatitis have an increased risk of developing pancreatic cancer.

Biliary obstruction: Occurs when fibrosis compresses the common bile duct, leading to **jaundice**.

Summary of Key Points for Chronic Pancreatitis:

Chronic pancreatitis is a long-term inflammatory condition of the pancreas that leads to **irreversible damage** and loss of both **exocrine** and **endocrine** function.

The primary symptoms are **chronic epigastric pain**, **steatorrhoea**, **malabsorption**, and **weight loss**. Diabetes may develop in the later stages.

Imaging (ultrasound, CT, or MRCP) is used to diagnose structural changes in the pancreas, such as **calcifications** and ductal irregularities.

Pancreatic enzyme replacement therapy (PERT) and **pain management** are key components of treatment.

Complications include pancreatic insufficiency, diabetes, pseudocysts, and an increased risk of **pancreatic cancer**.

188. Pancreatic Cancer

1. Detailed Definition of Pancreatic Cancer:

Pancreatic cancer is a **malignant tumour** originating from the **pancreas**, an organ responsible for producing digestive enzymes and hormones such as insulin. The majority of pancreatic cancers are **adenocarcinomas**, which arise from the **exocrine cells** of the pancreas, accounting for over 90% of cases. Pancreatic cancer is often asymptomatic in the early stages and has a **poor prognosis** due to late presentation.

2. Common Presenting Complaints and Symptoms:

Pancreatic cancer often presents late due to its **non-specific symptoms**, which include:

Painless jaundice: Caused by bile duct obstruction due to a tumour in the head of the pancreas.

Weight loss: Unexplained, progressive weight loss is common.

Epigastric or upper abdominal pain: The pain may **radiate to the back** and is often worsened by lying supine or after eating.

Dark urine and pale stools: Caused by obstruction of the bile duct, leading to reduced bilirubin excretion.

Pruritus: Itching due to the buildup of bile salts in the skin.

New-onset diabetes: Particularly in older adults without risk factors.

Nausea, vomiting, and anorexia: Due to tumour mass effects or gastric outlet obstruction in advanced cases.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated **bilirubin**, **alkaline phosphatase (ALP)**, and **gamma-glutamyl transferase (GGT)** indicate biliary obstruction.

Tumour markers:

CA 19-9: A marker that may be elevated in pancreatic cancer but is not specific, as it can also be raised in benign conditions like cholangitis or pancreatitis.

Full blood count (FBC): May show anaemia or other paraneoplastic features.

b) Imaging:

Abdominal Ultrasound:

First-line imaging to assess **biliary ductal dilatation** and **obstructive jaundice** caused by a pancreatic mass.

Contrast-enhanced CT scan:

The **gold standard** for diagnosing pancreatic cancer. A CT scan can identify the **tumour**, assess its size, and evaluate for **metastasis**.

Endoscopic Ultrasound (EUS):

Useful for diagnosing small tumours not visible on a CT scan and for obtaining **biopsies** to confirm the diagnosis.

Magnetic Resonance Cholangiopancreatography (MRCP):

Non-invasive imaging used to evaluate the **biliary and pancreatic ducts**, often employed if **obstruction** is suspected.

Endoscopic Retrograde Cholangiopancreatography (ERCP):

Can be used to **relieve bile duct obstruction** by placing a stent, but it is less commonly used as a diagnostic tool.

4. Explanation of Investigations:

CA 19-9: A tumour marker that can be elevated in pancreatic cancer. However, it is not diagnostic, as levels can also be raised in benign biliary disease. It is useful for **monitoring treatment response** and detecting **recurrence**.

CT scan: Provides detailed imaging of the **pancreatic tumour**, its extent, and any metastasis to surrounding structures.

EUS: Allows for better visualisation of small tumours and enables **fine-needle aspiration (FNA)** for biopsy to confirm the diagnosis histologically.

5. Diagnosis Criteria for Pancreatic Cancer:

Pancreatic cancer is diagnosed based on:

Imaging findings: A mass seen on **CT scan, MRI, or EUS**.

Histological confirmation: A biopsy obtained via **EUS** or **ERCP** showing adenocarcinoma or other pancreatic malignancies.

Elevated tumour markers (CA 19-9) may support the diagnosis, although they are not specific.

6. First-Line Therapy According to Guidelines:

a) Surgical Management:

Curative surgery:

Pancreaticoduodenectomy (Whipple procedure): The primary curative treatment for patients with **resectable** tumours in the **head of the pancreas**. It involves removing the head of the pancreas, the duodenum, part of the stomach, and the bile duct.

Distal pancreatectomy: Used for tumours in the **tail of the pancreas**.

Only 10-20% of patients are suitable for curative surgery due to the late presentation of the disease.

b) Palliative Care:

Biliary stenting: For patients with **biliary obstruction** causing jaundice. Stents can be placed during **ERCP** to relieve obstruction.

Pain management: Pain control is crucial in advanced disease, often using **opioids**.

Chemotherapy: Palliative chemotherapy with agents like **gemcitabine** or **FOLFIRINOX** (combination of fluorouracil, leucovorin, irinotecan, and oxaliplatin) is used to prolong survival and manage symptoms in patients with **unresectable** pancreatic cancer.

Radiotherapy: May be considered in some patients to relieve pain or control tumour growth, but it is not routinely used.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Surgery: Patients with **metastatic disease** or **locally advanced unresectable tumours** are generally not candidates for curative surgery.

b) Second-Line Therapy:

Palliative chemotherapy: Used for patients who are not surgical candidates. Second-line options include different chemotherapy regimens, depending on the patient's performance status and response to first-line treatments.

Endoscopic or percutaneous drainage: In patients with inoperable tumours causing biliary obstruction, **percutaneous transhepatic biliary drainage (PTBD)** may be necessary if ERCP stenting is not feasible.

8. Routine Monitoring and Follow-Up:

Tumour markers (CA 19-9): Regular monitoring to assess treatment response and detect recurrence.

CT scans: Routine imaging every 3–6 months in patients undergoing treatment to monitor the tumour's size and assess for metastasis.

Palliative follow-up: Regular assessment of **symptom control**, including pain, nutrition, and management of biliary obstruction or gastric outlet obstruction.

9. Complications of Pancreatic Cancer:

Biliary obstruction: Leading to **jaundice**, **pruritus**, and **cholestatic liver injury**.

Gastric outlet obstruction: Occurs in advanced tumours, causing vomiting and feeding difficulties.

Malnutrition: Due to poor absorption, anorexia, and tumour-related cachexia.

Diabetes mellitus: Occurs due to pancreatic insufficiency.

Metastasis: Common sites include the **liver**, **peritoneum**, and **lungs**.

Summary of Key Points for Pancreatic Cancer:

Pancreatic cancer is a highly aggressive cancer with a poor prognosis due to late presentation.

Common symptoms include **painless jaundice**, **weight loss**, and **epigastric pain** radiating to the back.

Imaging (CT scan, EUS) and biopsy are crucial for diagnosis. **CA 19-9** is used to monitor disease progression but is not diagnostic.

Surgery (e.g., Whipple procedure) is the only potential cure, but most patients present too late for curative resection.

Palliative care, including **biliary stenting**, **chemotherapy**, and **pain management**, is key to managing symptoms and improving quality of life in advanced disease.

189. Acute Hepatic Failure

1. Detailed Definition of Acute Hepatic Failure:

Acute hepatic failure (also known as **acute liver failure**) is a life-threatening condition characterised by the **rapid deterioration** of liver function, leading to **coagulopathy** (impaired blood clotting) and **hepatic encephalopathy** (brain dysfunction due to liver failure) in patients without pre-existing liver disease. The decline in liver function typically occurs within **days to weeks** and can result in multi-organ failure.

The most common causes include **paracetamol (acetaminophen) overdose**, **viral hepatitis**, and **drug-induced liver injury**.

2. Common Presenting Complaints and Symptoms:

Symptoms of acute hepatic failure include:

Jaundice: Yellowing of the skin and eyes due to hyperbilirubinemia.

Fatigue and malaise.

Confusion, drowsiness, or altered mental state: Due to **hepatic encephalopathy**, ranging from mild confusion to deep coma.

Nausea and vomiting.

Abdominal pain: Typically in the upper right quadrant (RUQ).

Pruritus: Itching due to bile salt deposition.

Bleeding: Tendency for easy bruising, nosebleeds, and bleeding gums due to coagulopathy.

Ascites: Accumulation of fluid in the abdomen in some cases.

Oliguria or anuria: Reduced or absent urine output, indicating renal dysfunction (hepatorenal syndrome).

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

ALT and **AST** are usually markedly elevated.

Bilirubin: Raised, indicating impaired liver function and bile metabolism.

Alkaline phosphatase (ALP) and **gamma-glutamyl transferase (GGT):** May also be elevated.

Prothrombin time (PT) or International Normalised Ratio (INR):

Prolonged **INR** (greater than 1.5) is a hallmark of **acute hepatic failure**, reflecting impaired synthesis of clotting factors.

Ammonia levels: Elevated in hepatic encephalopathy due to impaired detoxification by the liver.

Urea and electrolytes: Monitor renal function and assess for electrolyte imbalances.

Serum albumin: Low, reflecting reduced liver synthetic function.

Arterial blood gases (ABG): To detect metabolic disturbances such as **lactic acidosis**.

Viral serology: To check for causes like **hepatitis A, B, C, D, and E**.

Paracetamol levels: Important in suspected paracetamol overdose.

b) Imaging:

Abdominal Ultrasound:

Used to assess liver size, check for biliary obstruction, and rule out liver masses or cirrhosis.

CT scan or MRI of the abdomen:

Sometimes required to exclude other causes of liver dysfunction or to assess for complications such as liver necrosis.

Liver biopsy:

Rarely performed in acute hepatic failure due to the risk of bleeding, but may be considered in select cases to determine the underlying cause if the diagnosis remains unclear.

4. Explanation of Investigations:

LFTs: Elevation of **AST/ALT** suggests hepatocellular damage, while raised **bilirubin** indicates impaired bile excretion.

INR/PT: The liver produces clotting factors, so a prolonged **INR** is a key indicator of liver dysfunction.

Ammonia: High levels cause encephalopathy, as the liver is unable to detoxify ammonia.

Ultrasound: Useful to rule out biliary obstruction and assess liver size, helping to differentiate acute liver failure from chronic liver disease.

5. Diagnosis Criteria for Acute Hepatic Failure:

The diagnosis of **acute hepatic failure** is based on:

Acute onset of liver dysfunction with evidence of:

Coagulopathy (**INR > 1.5**).

Development of **hepatic encephalopathy**.

Absence of pre-existing cirrhosis or chronic liver disease.

Evidence of hepatocellular injury on blood tests (e.g., elevated transaminases) and imaging.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

Fluid resuscitation: Intravenous fluids to maintain blood pressure and renal perfusion.

Management of hypoglycaemia: Liver failure often leads to hypoglycaemia due to impaired gluconeogenesis. Regular blood glucose monitoring and **IV glucose** should be administered as needed.

Nutritional support: **Enteral feeding** is preferred to maintain nutrition.

b) Specific Treatments:

Paracetamol overdose: Administer **N-acetylcysteine (NAC)**, which replenishes glutathione and prevents further liver damage. NAC is effective if given early but can still be beneficial later.

Hepatic encephalopathy: Manage with **lactulose** to reduce ammonia absorption, and **rifaximin** to reduce ammonia-producing bacteria in the gut.

Infection management: Prophylactic or therapeutic antibiotics if bacterial infection is suspected, as patients with acute liver failure are prone to infections.

c) Definitive Treatment:

Liver transplantation is the definitive treatment for patients with **acute hepatic failure** who are at risk of liver failure progression and death. Early referral to a transplant centre is crucial.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

NSAIDs should be avoided as they may worsen renal function and gastrointestinal bleeding.

b) Second-Line Therapy:

If **N-acetylcysteine** does not improve liver function, particularly in paracetamol overdose, liver transplantation is the next option.

In severe hepatic encephalopathy, **intubation and ventilation** may be required to protect the airway.

8. Routine Monitoring and Follow-Up:

Daily monitoring of LFTs, INR, and electrolytes:

Frequent checks of liver function and clotting parameters.

Close monitoring for encephalopathy progression:

Regular neurological assessments are critical to detect the worsening of hepatic encephalopathy.

Fluid balance and renal function:

Monitor for **hepatorenal syndrome** with frequent blood pressure and urine output checks.

9. Complications of Acute Hepatic Failure:

Cerebral oedema: A serious complication of hepatic encephalopathy that can lead to brain herniation.

Sepsis: Patients with acute hepatic failure are at increased risk of bacterial and fungal infections.

Acute renal failure (hepatorenal syndrome): Due to circulatory collapse and reduced renal perfusion.

Coagulopathy and bleeding: Due to decreased synthesis of clotting factors, leading to an increased risk of gastrointestinal and intracranial bleeding.

Hypoglycaemia: Due to impaired hepatic glucose production.

Multi-organ failure: In severe cases, liver failure can lead to failure of other organs, such as the kidneys, lungs, and heart.

Summary of Key Points for Acute Hepatic Failure:

Acute hepatic failure is characterised by **rapid liver dysfunction**, leading to **coagulopathy** and **hepatic encephalopathy**.

Paracetamol overdose and **viral hepatitis** are the most common causes.

Diagnosis is confirmed by clinical presentation, blood tests (elevated **ALT**, **bilirubin**, and **INR > 1.5**), and imaging.

Management includes **N-acetylcysteine** for paracetamol overdose, **supportive care**, **management of hepatic encephalopathy**, and **early consideration of liver transplantation**.

Complications include **cerebral oedema**, **renal failure**, **sepsis**, and **coagulopathy**, necessitating close monitoring and timely intervention.

190. Acute Hepatitis

1. Detailed Definition of Acute Hepatitis:

Acute hepatitis is the **rapid onset of liver inflammation**, usually caused by viral infections, toxins, or drug-induced injury. The condition is marked by **hepatocellular injury** and can range from mild, self-limiting disease to severe, fulminant liver failure. Acute hepatitis typically lasts for less than six months and may resolve spontaneously or progress to chronic hepatitis in some cases.

2. Common Presenting Complaints and Symptoms:

Patients with acute hepatitis may present with:

Jaundice: Yellowing of the skin and eyes due to elevated bilirubin levels.

Fatigue and malaise: A common early symptom due to systemic inflammation.

Loss of appetite and nausea.

Abdominal pain: Typically in the right upper quadrant (RUQ), due to liver inflammation.

Dark urine: Due to increased bilirubin excretion.

Pale stools: Caused by reduced bile excretion into the gut.

Fever: Seen in infectious hepatitis (e.g., viral hepatitis).

Pruritus: Itching due to bile salt deposition in the skin.

Arthralgia and myalgia: May be present, particularly in **viral hepatitis** (e.g., hepatitis B).

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated aminotransferases (ALT and AST): These enzymes are markers of hepatocellular injury. ALT is often higher than AST in viral hepatitis.

Bilirubin: Raised, leading to jaundice.

Alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT): These may be mildly elevated, indicating bile duct involvement.

Prothrombin time (PT)/INR: Prolonged in severe cases, indicating impaired liver function.

Viral serology:

Hepatitis A IgM: Positive in acute hepatitis A infection.

Hepatitis B surface antigen (HBsAg) and hepatitis B core antibody (anti-HBc IgM): Positive in acute hepatitis B infection.

Hepatitis C antibody and PCR: Used to detect hepatitis C infection.

Hepatitis E IgM: Used to diagnose hepatitis E infection.

Full blood count (FBC): To check for anaemia or thrombocytopenia.

Urea and electrolytes: To assess renal function, as acute hepatitis can sometimes be associated with renal impairment.

b) Imaging:

Abdominal Ultrasound:

Used to assess liver size and exclude biliary obstruction or gallstones that could cause secondary liver inflammation.

CT or MRI of the liver:

Rarely needed in acute hepatitis but can help assess liver structure or rule out other causes of liver disease if the diagnosis is uncertain.

4. Explanation of Investigations:

LFTs: Elevated **ALT/AST** suggests **hepatocellular injury**. Elevated **bilirubin** leads to jaundice, and prolonged **INR** indicates liver dysfunction.

Viral serology: Used to identify the specific viral cause of acute hepatitis, such as **hepatitis A, B, C, D, or E**.

Ultrasound: Helps exclude **biliary obstruction** and assesses liver size and structure.

5. Diagnosis Criteria for Acute Hepatitis:

The diagnosis of acute hepatitis is based on:

Clinical symptoms: Jaundice, fatigue, nausea, and right upper quadrant pain.

Laboratory findings:

Elevated **ALT** and **AST** levels (often greater than 10 times the upper limit of normal).

Bilirubin elevation causing jaundice.

Positive viral serology if caused by a viral infection (e.g., **hepatitis A, B, or C**).

Imaging: Used to exclude other causes, such as biliary obstruction.

6. First-Line Therapy According to Guidelines:

a) Supportive Care:

Rest and hydration: Encourage adequate rest and oral hydration.

Nutritional support: Patients may need dietary adjustments, particularly if nausea and anorexia are present.

Avoid alcohol and hepatotoxic medications: Patients should avoid any substances that could further stress the liver.

Antiemetics: For patients experiencing significant nausea and vomiting.

b) Specific Treatment:

Hepatitis A and E: No specific antiviral therapy is available; treatment is supportive.

Hepatitis B: Antiviral agents (e.g., tenofovir, entecavir) may be used in patients with severe acute hepatitis B or those at high risk of progression to chronic infection.

Hepatitis C: In some cases, **direct-acting antivirals (DAAs)** may be initiated if acute infection is diagnosed early.

Paracetamol overdose: Treated with **N-acetylcysteine (NAC)**, which replenishes glutathione and reduces liver damage.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

NSAIDs: Should be avoided as they can worsen liver dysfunction and increase the risk of gastrointestinal bleeding in patients with liver disease.

b) Second-Line Therapy:

For severe cases of acute hepatitis leading to **acute liver failure**, patients may require referral to a **liver transplant centre** for evaluation for possible **liver transplantation**.

8. Routine Monitoring and Follow-Up:

Frequent blood tests:

LFTs, **bilirubin**, and **INR** should be monitored regularly to assess liver function.

Renal function should be checked to assess for potential hepatorenal syndrome.

Monitor for progression to chronic hepatitis:

In cases of **hepatitis B** or **C**, follow-up serology is required to assess for viral clearance or chronic infection.

Encephalopathy monitoring:

Patients with signs of confusion or altered mental status should be closely monitored for **hepatic encephalopathy**.

9. Complications of Acute Hepatitis:

Acute liver failure: Characterised by **coagulopathy** and **hepatic encephalopathy**. This is a rare but serious complication.

Hepatorenal syndrome: Acute kidney injury secondary to liver failure.

Chronic hepatitis: Some cases of acute viral hepatitis (particularly **hepatitis B** and **hepatitis C**) can progress to chronic infection and liver disease.

Cirrhosis: Chronic liver damage can eventually lead to cirrhosis in cases of ongoing liver inflammation.

Portal hypertension: Due to long-term liver injury.

Summary of Key Points for Acute Hepatitis:

Acute hepatitis is a sudden inflammation of the liver, often caused by **viral infections, toxins, or drugs**.

Common symptoms include **jaundice, fatigue, nausea, and RUQ pain**.

Diagnosis is confirmed by **elevated ALT/AST, bilirubin, and positive viral serology**.

Treatment is largely **supportive**, with specific antiviral therapy for **hepatitis B and C** in some cases.

Complications include **acute liver failure, hepatorenal syndrome**, and the progression to **chronic hepatitis or cirrhosis**.

191. Alcoholic Hepatitis

1. Detailed Definition of Alcoholic Hepatitis:

Alcoholic hepatitis is an acute inflammation of the liver caused by excessive alcohol consumption. It is characterised by **hepatocellular injury, necrosis, and inflammation**, which may result in liver failure. Alcoholic hepatitis is part of a spectrum of **alcohol-related liver disease (ARLD)**, ranging from fatty liver to cirrhosis. Severe alcoholic hepatitis has a high mortality rate, and continued alcohol consumption exacerbates the condition.

2. Common Presenting Complaints and Symptoms:

Patients with alcoholic hepatitis often present with:

Jaundice: Yellowing of the skin and eyes, due to impaired bilirubin metabolism.

Right upper quadrant (RUQ) pain: Due to liver inflammation.

Hepatomegaly: Enlarged liver, which can be palpable.

Anorexia and weight loss: Due to the liver's impaired metabolic function.

Nausea and vomiting.

Fatigue and malaise.

Fever: Low-grade fever may be present in moderate to severe cases.

Ascites: Accumulation of fluid in the abdomen due to portal hypertension and hypoalbuminaemia.

Signs of encephalopathy: Confusion, disorientation, or drowsiness, due to the buildup of toxins that the liver cannot clear (hepatic encephalopathy).

Spider naevi, palmar erythema, and peripheral oedema in more advanced cases.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

ALT/AST ratio: In alcoholic hepatitis, **AST** is usually greater than **ALT**, typically with a ratio of **2:1** or more.

Bilirubin: Raised, reflecting liver dysfunction and jaundice.

Alkaline phosphatase (ALP) and **gamma-glutamyl transferase (GGT):** Often raised, indicating cholestasis or biliary involvement.

Prothrombin time (PT)/INR: Prolonged, indicating impaired synthesis of clotting factors by the liver.

Serum albumin: Low in severe cases, reflecting reduced synthetic function of the liver.

Full blood count (FBC):

Leukocytosis: Raised white cell count, often present in alcoholic hepatitis.

Anaemia: Due to gastrointestinal bleeding or bone marrow suppression.

Thrombocytopaenia: Low platelet count may suggest cirrhosis or alcohol-related bone marrow suppression.

Urea and electrolytes: To assess renal function and electrolyte disturbances.

Serum creatinine: Assessed for potential kidney dysfunction, especially in hepatorenal syndrome.

Serum ammonia: Elevated in hepatic encephalopathy.

b) Imaging:

Abdominal Ultrasound:

Used to assess liver size and structure, check for **ascites**, and rule out biliary obstruction or cirrhosis.

CT or MRI of the abdomen:

Can provide more detailed imaging to assess for complications such as **hepatic abscess**, **portal vein thrombosis**, or **malignancy**.

c) Special Scoring Systems:

Maddrey Discriminant Function (DF): A tool used to assess the severity of alcoholic hepatitis and guide treatment decisions (e.g., corticosteroid therapy).

DF > 32 suggests severe alcoholic hepatitis and warrants consideration for corticosteroids.

Glasgow Alcoholic Hepatitis Score (GAHS): Used to predict the prognosis of patients with alcoholic hepatitis.

4. Explanation of Investigations:

AST/ALT ratio: A ratio of **AST > ALT** (typically > 2:1) is characteristic of alcoholic liver disease.

Bilirubin: Elevated levels indicate impaired bile metabolism, leading to jaundice.

Maddrey Discriminant Function (DF): A score that helps determine the severity of alcoholic hepatitis. It is calculated using prothrombin time and serum bilirubin levels.

5. Diagnosis Criteria for Alcoholic Hepatitis:

The diagnosis of alcoholic hepatitis is based on:

Clinical features: History of heavy alcohol consumption, jaundice, fever, and RUQ pain.

Laboratory findings:

AST > ALT with a ratio > 2:1.

Elevated bilirubin and **prolonged INR**.

Imaging: Ultrasound or CT scan to rule out other causes of liver disease and assess liver structure.

Exclusion of other causes: Viral hepatitis, autoimmune liver disease, and drug-induced liver injury should be excluded.

6. First-Line Therapy According to Guidelines:

a) Abstinence from Alcohol:

Absolute alcohol cessation: The most important step in managing alcoholic hepatitis. Continued alcohol consumption leads to progression of liver damage.

b) Medical Treatment:

Nutritional support:

Patients are often malnourished, and adequate caloric intake (35-40 kcal/kg/day) with sufficient protein (1.2-1.5 g/kg/day) is essential.

Enteral feeding should be considered for patients with poor oral intake.

Corticosteroids (e.g., **prednisolone 40 mg daily** for 28 days):

Indicated in patients with severe alcoholic hepatitis (e.g., **Maddrey DF > 32**).

Reduces inflammation and improves survival in some patients.

Pentoxifylline:

May be considered if corticosteroids are contraindicated, particularly in patients with renal impairment. It reduces the risk of hepatorenal syndrome.

c) Management of Complications:

Hepatic encephalopathy: Treated with **lactulose** to reduce ammonia absorption and **rifaximin** to reduce gut bacteria that produce ammonia.

Ascites: Managed with **diuretics** (e.g., **spironolactone**, **furosemide**) and **paracentesis** if large-volume ascites is present.

Infection: Patients are at increased risk of **spontaneous bacterial peritonitis** (SBP) and other infections, which should be treated with **antibiotics**.

d) Liver Transplantation:

Liver transplantation is the definitive treatment for patients with end-stage liver disease due to alcoholic hepatitis, though strict criteria for abstinence are often required.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Corticosteroids should be avoided in patients with active infections, gastrointestinal bleeding, or renal failure.

b) Second-Line Therapy:

Pentoxifylline: Used as an alternative to corticosteroids in patients with contraindications or intolerance.

N-acetylcysteine (NAC): May be used alongside corticosteroids in severe cases to reduce oxidative stress and inflammation.

8. Routine Monitoring and Follow-Up:

Frequent LFTs: Monitor liver enzymes, bilirubin, and INR to assess improvement or progression of liver function.

Nutritional status: Regular assessment of nutritional intake and supplementation as needed.

Monitor for complications:

Renal function and **electrolytes** to detect hepatorenal syndrome.

Encephalopathy should be monitored closely with regular neurological assessments.

Regular **ultrasound** to monitor for **ascites** and other complications.

9. Complications of Alcoholic Hepatitis:

Acute liver failure: Severe alcoholic hepatitis can lead to fulminant liver failure.

Portal hypertension: Due to scarring and fibrosis, which may result in ascites, varices, and splenomegaly.

Hepatorenal syndrome: Renal failure secondary to advanced liver disease.

Hepatic encephalopathy: Due to the buildup of toxins, particularly ammonia.

Gastrointestinal bleeding: From **oesophageal varices** or **peptic ulcers** due to portal hypertension or alcohol-induced gastric damage.

Cirrhosis: Chronic alcohol consumption often leads to cirrhosis and liver failure.

Summary of Key Points for Alcoholic Hepatitis:

Alcoholic hepatitis is an acute inflammatory condition of the liver caused by excessive alcohol consumption, with a poor prognosis if alcohol intake continues.

Common symptoms include **jaundice**, **RUQ pain**, **fever**, and **fatigue**.

Diagnosis is based on **clinical history**, **LFTs** (AST/ALT ratio > 2:1), and exclusion of other causes.

Treatment includes **alcohol abstinence**, **nutritional support**, and **corticosteroids** or **pentoxifylline** in severe cases.

Complications include **acute liver failure**, **hepatorenal syndrome**, and progression to **cirrhosis**.

192. Cirrhosis

1. Detailed Definition of Cirrhosis:

Cirrhosis is the **end-stage of chronic liver disease**, characterised by **irreversible scarring (fibrosis)** of the liver and **regenerative nodules**. The liver's normal structure and function are disrupted, leading to progressive **hepatic dysfunction** and **portal hypertension**. Cirrhosis can result from a variety of chronic liver conditions, including **alcoholic liver disease**, **viral hepatitis**, and **non-alcoholic fatty liver disease (NAFLD)**.

2. Common Presenting Complaints and Symptoms:

Cirrhosis may present with a range of symptoms, particularly in advanced stages:

Fatigue and **weakness**: Common, non-specific symptoms.

Jaundice: Yellowing of the skin and eyes, due to impaired bilirubin metabolism.

Pruritus: Itching caused by bile salt deposition in the skin.

Ascites: Fluid accumulation in the abdomen due to portal hypertension and hypoalbuminaemia.

Peripheral oedema: Swelling in the legs and ankles.

Spider naevi and **palmar erythema**: Caused by hyperoestrogenism due to impaired liver metabolism.

Hepatomegaly or **splenomegaly**: Enlarged liver and spleen.

Easy bruising and **bleeding**: Due to reduced synthesis of clotting factors.

Encephalopathy: Confusion, personality changes, and drowsiness due to hepatic encephalopathy from ammonia buildup.

Caput medusae: Enlarged veins visible on the abdomen due to portal hypertension.

Gastrointestinal bleeding: From oesophageal varices or gastric varices due to portal hypertension.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated bilirubin: Due to impaired conjugation and excretion.

Low albumin: Reflecting impaired liver synthetic function.

Elevated alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT): Indicative of cholestasis or biliary involvement.

Prothrombin time (PT)/INR: Prolonged due to impaired production of clotting factors.

AST/ALT ratio: In advanced cirrhosis, both AST and ALT may be elevated, with AST often higher than ALT.

Full blood count (FBC):

Thrombocytopaenia: Due to splenic sequestration in portal hypertension.

Anaemia: May be due to gastrointestinal bleeding or bone marrow suppression.

Urea and electrolytes: To assess renal function and detect complications such as hepatorenal syndrome.

Ammonia levels: Elevated in hepatic encephalopathy.

b) Imaging:

Abdominal Ultrasound:

First-line imaging for assessing liver size, texture, presence of **ascites**, and spleen size.

May reveal a **nodular liver** indicative of cirrhosis.

FibroScan (Transient elastography):

A non-invasive test used to assess liver stiffness and fibrosis. High scores suggest advanced fibrosis or cirrhosis.

CT or MRI:

Used to assess the liver for masses (e.g., **hepatocellular carcinoma**) and detailed structural changes in the liver.

Endoscopy:

Performed to detect **oesophageal varices**, a complication of portal hypertension.

c) Special Tests:

Liver biopsy:

Although not routinely performed, a biopsy can confirm cirrhosis by showing **fibrosis** and **regenerative nodules**.

4. Explanation of Investigations:

LFTs: Elevated **bilirubin** and **AST/ALT** indicate hepatocellular damage, while low **albumin** and prolonged **INR** reflect liver dysfunction.

FibroScan: Measures liver stiffness, with higher values indicating significant fibrosis or cirrhosis.

Endoscopy: Used to screen for **varices**, a common complication of cirrhosis and portal hypertension.

5. Diagnosis Criteria for Cirrhosis:

Cirrhosis is diagnosed based on:

Clinical features: Signs such as **jaundice**, **ascites**, **hepatic encephalopathy**, and **spider naevi**.

Laboratory findings: Elevated **LFTs**, **low albumin**, **prolonged INR**, and **thrombocytopenia**.

Imaging: Ultrasound or **FibroScan** revealing a **nodular liver** and signs of portal hypertension.

Liver biopsy: If needed, confirms the presence of **fibrosis** and **regenerative nodules**.

6. First-Line Therapy According to Guidelines:

a) Management of the Underlying Cause:

Alcohol cessation: Crucial in alcoholic cirrhosis. Abstaining from alcohol may prevent further liver damage.

Antiviral therapy: For patients with cirrhosis due to **viral hepatitis** (e.g., hepatitis B or C).

Weight loss: In patients with cirrhosis secondary to **NAFLD**.

b) Management of Complications:

Ascites: Managed with:

Salt restriction: Sodium intake < 2g/day.

Diuretics: **Spironolactone** (first-line) and **furosemide** for fluid retention.

Paracentesis: Therapeutic removal of ascitic fluid in cases of **tense ascites**.

Hepatic encephalopathy: Treated with **lactulose** to reduce ammonia absorption and **rifaximin** to reduce gut bacteria that produce ammonia.

Oesophageal varices:

Endoscopic variceal ligation (EVL) for large varices.

Non-selective beta-blockers (e.g., **propranolol**) to reduce portal pressure and prevent bleeding.

Spontaneous bacterial peritonitis (SBP):

Prophylactic **antibiotics** (e.g., **ciprofloxacin**) for patients with low protein ascites or a history of SBP.

Hepatorenal syndrome:

Managed with **terlipressin** and **albumin**. Renal replacement therapy (e.g., dialysis) may be required.

c) Liver Transplantation:

Liver transplantation is the definitive treatment for patients with **decompensated cirrhosis** or those at risk of liver failure.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

NSAIDs should be avoided as they may worsen renal function and cause gastrointestinal bleeding in cirrhotic patients.

b) Second-Line Therapy:

Terlipressin: For treating **hepatorenal syndrome** and controlling variceal bleeding.

TIPS (Transjugular intrahepatic portosystemic shunt): A second-line option for patients with **refractory ascites** or recurrent variceal bleeding. It reduces portal pressure by creating a shunt between the portal and hepatic veins.

8. Routine Monitoring and Follow-Up:

Frequent blood tests:

Regular monitoring of **LFTs**, **INR**, and **albumin** to assess liver function.

Renal function should also be monitored closely to detect hepatorenal syndrome.

Abdominal Ultrasound and AFP levels:

Regular screening every 6 months for **hepatocellular carcinoma** in patients with cirrhosis.

Endoscopic surveillance:

Regular screening for **oesophageal varices** every 2-3 years in patients with cirrhosis.

9. Complications of Cirrhosis:

Hepatic encephalopathy: Confusion, drowsiness, and personality changes due to ammonia buildup.

Ascites: Fluid accumulation in the peritoneal cavity, leading to abdominal distension.

Oesophageal varices: Dilated veins in the oesophagus that can rupture and cause life-threatening bleeding.

Spontaneous bacterial peritonitis (SBP): Infection of ascitic fluid without an obvious source of infection.

Hepatocellular carcinoma (HCC): Cirrhosis is a major risk factor for developing HCC.

Portal hypertension: Increased pressure in the portal venous system, leading to ascites, varices, and splenomegaly.

Hepatorenal syndrome: A type of kidney failure that occurs in advanced cirrhosis.

193. Non-Alcoholic Fatty Liver Disease (NAFLD)

1. Detailed Definition of NAFLD:

Non-Alcoholic Fatty Liver Disease (NAFLD) is a spectrum of liver disorders characterised by the accumulation of fat in the liver (**steatosis**) without significant alcohol consumption (typically defined as < 20g of alcohol per day). NAFLD ranges from **simple steatosis** (fat accumulation without inflammation or damage) to **non-alcoholic steatohepatitis (NASH)**, which involves inflammation and can progress to **fibrosis**, **cirrhosis**, and even **hepatocellular carcinoma (HCC)**.

2. Common Presenting Complaints and Symptoms:

Many patients with NAFLD are **asymptomatic** and the condition is often discovered incidentally during investigations for other health issues. When symptoms do occur, they may include:

Fatigue: A common non-specific symptom.

Mild right upper quadrant (RUQ) pain or discomfort: Due to liver enlargement.

Hepatomegaly: Enlarged liver, sometimes palpable on physical examination.

Jaundice: Rare in early stages but can occur in advanced disease.

Weight gain or obesity: Often associated with metabolic syndrome (obesity, type 2 diabetes, hypertension, and dyslipidaemia).

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated ALT and AST: These liver enzymes are often mildly elevated, with **ALT** usually higher than **AST** (opposite of alcoholic liver disease).

Bilirubin, ALP, and GGT: Usually normal or mildly elevated.

Fasting blood glucose/HbA1c: To screen for **diabetes** or **pre-diabetes**, which are common in patients with NAFLD.

Lipid profile: To assess for **hyperlipidaemia**.

Serum albumin and INR: Assessed in more advanced stages to evaluate liver synthetic function.

b) Imaging:

Abdominal Ultrasound:

First-line imaging to assess for **hepatic steatosis**. Ultrasound may show a **hyperechoic ("bright") liver**, which is suggestive of fat deposition.

Transient Elastography (FibroScan):

Used to assess liver **stiffness**, which correlates with the degree of **fibrosis**. It is a non-invasive way to evaluate for progression to **fibrosis** or **cirrhosis**.

MRI or CT Scan:

These may be used for a more detailed assessment of liver fat content and fibrosis but are generally not first-line investigations.

Liver Biopsy (Rare):

Performed in cases where the diagnosis is uncertain or to assess the degree of **inflammation** and **fibrosis** in suspected NASH.

4. Explanation of Investigations:

LFTs: Elevated **ALT** and **AST** suggest liver inflammation, but levels may be normal in mild cases. Other LFT abnormalities are rare unless the disease progresses to cirrhosis.

FibroScan: Measures liver stiffness to evaluate the degree of fibrosis, with higher scores indicating significant fibrosis or cirrhosis.

Ultrasound: Helps confirm fat accumulation in the liver and exclude other causes such as gallstones or tumours.

5. Diagnosis Criteria for NAFLD:

The diagnosis of NAFLD is based on:

Evidence of hepatic steatosis on imaging (e.g., ultrasound or MRI).

Exclusion of significant alcohol intake (< 20g/day for women, < 30g/day for men).

Exclusion of other causes of liver disease (e.g., viral hepatitis, autoimmune liver disease, and drug-induced liver injury).

Metabolic risk factors: Most patients have associated conditions like **obesity**, **type 2 diabetes**, **hypertension**, or **dyslipidaemia**.

6. First-Line Therapy According to Guidelines:

a) Lifestyle Modifications:

Weight loss:

A gradual weight loss of **7-10%** is associated with significant improvement in liver histology, including reductions in fat, inflammation, and fibrosis.

Weight loss should be achieved through **dietary changes** and **increased physical activity**.

Dietary changes:

A **Mediterranean-style diet** (high in fruits, vegetables, whole grains, and healthy fats like olive oil) is recommended.

Reduce intake of **saturated fats**, **trans fats**, and **simple carbohydrates**.

Physical activity:

Aim for **150 minutes of moderate exercise per week** to improve insulin sensitivity and reduce liver fat.

b) Pharmacological Therapy:

Currently, there are no medications specifically licensed to treat NAFLD. However, treatment is aimed at controlling associated conditions, such as:

Metformin: Used in patients with **type 2 diabetes** to improve insulin sensitivity, but not specifically indicated for NAFLD.

Pioglitazone: A PPAR- γ agonist used to treat NASH in patients with diabetes.

Vitamin E (800 IU/day): May be considered in **non-diabetic** patients with NASH to reduce inflammation, but long-term safety concerns exist.

Statins: Used to manage dyslipidaemia but have no direct effect on liver histology in NAFLD.

GLP-1 agonists (e.g., liraglutide): May be used in patients with **type 2 diabetes** to help with weight loss and improve liver histology.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Vitamin E: Not recommended in patients with **diabetes** due to potential long-term risks (e.g., prostate cancer in men).

b) Second-Line Therapy:

Bariatric surgery: Considered for patients with **morbid obesity** (BMI > 40 kg/m²) or **BMI > 35 kg/m²** with comorbid conditions such as type 2 diabetes. Bariatric surgery can lead to significant weight loss and improvement in NAFLD.

Liver transplantation: In rare cases, for patients with NAFLD who progress to end-stage liver disease or hepatocellular carcinoma.

8. Routine Monitoring and Follow-Up:

Regular monitoring of liver function:

Patients should have **LFTs** checked every 6-12 months, especially if they have diabetes or other risk factors.

Imaging and FibroScan:

FibroScan can be repeated periodically (every 1-2 years) to monitor for progression to fibrosis or cirrhosis.

Monitoring for complications:

Screen for the development of **type 2 diabetes**, **hypertension**, and **dyslipidaemia** in patients with NAFLD.

9. Complications of NAFLD:

Non-Alcoholic Steatohepatitis (NASH): Inflammation and fibrosis that can progress to cirrhosis and liver failure.

Cirrhosis: The final stage of liver fibrosis, which can lead to **portal hypertension**, **ascites**, and **hepatic encephalopathy**.

Hepatocellular carcinoma (HCC): Patients with NASH cirrhosis are at increased risk of developing liver cancer.

Cardiovascular disease: NAFLD is strongly associated with an increased risk of **myocardial infarction**, **stroke**, and **cardiovascular death**.

Summary of Key Points for NAFLD:

NAFLD is characterised by fat accumulation in the liver in the absence of significant alcohol intake, often associated with **obesity**, **diabetes**, and **metabolic syndrome**.

Diagnosis is based on **imaging**, **exclusion of alcohol**, and exclusion of other liver diseases.

First-line treatment includes **lifestyle modification** with weight loss, diet, and exercise.

Complications include progression to **NASH**, **cirrhosis**, and **hepatocellular carcinoma**.

Patients should be regularly monitored for liver function and progression to **fibrosis** or **cirrhosis** using **LFTs**, **FibroScan**, and **imaging**.

194. Viral Hepatitis

1. Detailed Definition of Viral Hepatitis:

Viral hepatitis refers to **inflammation of the liver** caused by specific hepatotropic viruses. The most common forms of viral hepatitis are caused by **hepatitis A, B, C, D, and E viruses**. These viruses can lead to acute or chronic liver disease, with varying degrees of liver inflammation, fibrosis, and, in some cases, cirrhosis and liver cancer. Hepatitis can also be caused by other systemic viruses like **Epstein-Barr virus (EBV)** or **cytomegalovirus (CMV)**, but these are less common.

2. Common Presenting Complaints and Symptoms:

The presentation of viral hepatitis can vary from **asymptomatic** to **severe fulminant liver failure**, depending on the type and stage of infection. Typical symptoms include:

Acute Hepatitis:

Jaundice: Yellowing of the skin and eyes due to hyperbilirubinaemia.

Fatigue and malaise: Common early symptoms.

Anorexia, nausea, and vomiting: Gastrointestinal upset.

Abdominal pain: Typically in the right upper quadrant (RUQ), due to liver inflammation.

Dark urine and pale stools: Due to cholestasis and impaired bile excretion.

Low-grade fever: Particularly common in hepatitis A and E.

Chronic Hepatitis (Hepatitis B or C):

Many patients are **asymptomatic** until late in the disease.

Symptoms of **chronic liver disease**, such as **fatigue, weakness, easy bruising**, and **ascites** (fluid accumulation in the abdomen), can occur with advanced liver damage.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated ALT and AST: Indicate hepatocellular injury, with ALT often more elevated than AST.

Elevated bilirubin: May lead to jaundice in more severe cases.

Alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT): May be elevated if there is cholestasis.

Prothrombin time (PT)/INR: Prolonged in severe or chronic liver disease.

Viral serology:

Hepatitis A IgM: Indicates acute hepatitis A infection.

Hepatitis B serology:

HBsAg (hepatitis B surface antigen): Indicates current infection (acute or chronic).

Anti-HBc IgM: Indicates acute or recent infection.

Anti-HBc IgG: Indicates past or chronic infection.

HBeAg (hepatitis B e antigen): Indicates active viral replication.

Anti-HBs (hepatitis B surface antibody): Indicates recovery or successful vaccination.

Hepatitis C antibody and PCR: Detects past or current hepatitis C infection. A **positive PCR** confirms active infection.

Hepatitis D antibody: Only present in co-infection with hepatitis B.

Hepatitis E IgM: Confirms acute hepatitis E infection.

Full blood count (FBC): May reveal **thrombocytopaenia** or **leukopaenia** in severe cases.

Urea and electrolytes: To assess renal function and rule out complications such as hepatorenal syndrome.

b) Imaging:

Abdominal Ultrasound:

Used to assess liver size and structure, detect complications like **ascites**, and exclude biliary obstruction.

Transient Elastography (FibroScan):

May be used in chronic hepatitis to assess **liver stiffness**, which correlates with fibrosis.

c) Special Tests:

Hepatitis B and C viral load: Quantitative PCR to assess viral replication and guide treatment.

Liver biopsy: Rarely performed in acute hepatitis but may be used in chronic hepatitis to assess the degree of inflammation and fibrosis.

4. Explanation of Investigations:

LFTs: Elevated **ALT/AST** indicates hepatocellular damage, while elevated **bilirubin** causes jaundice. **ALP and GGT** suggest cholestasis.

Viral serology: Determines the type of viral hepatitis, whether the infection is acute or chronic, and if the patient is contagious.

FibroScan: Used in chronic hepatitis to evaluate liver fibrosis and the risk of progression to cirrhosis.

5. Diagnosis Criteria for Viral Hepatitis:

Diagnosis is made based on:

Clinical features: Jaundice, fatigue, RUQ pain, dark urine, and pale stools.

Laboratory findings:

Elevated ALT/AST and bilirubin.

Viral serology specific to the hepatitis virus.

Imaging: Ultrasound to assess liver size, exclude other causes, and check for complications.

Liver biopsy: In chronic hepatitis, a biopsy can help assess inflammation and fibrosis.

6. First-Line Therapy According to Guidelines:

a) Supportive Care for Acute Viral Hepatitis:

Rest and hydration: Encourage adequate oral hydration and rest.

Nutritional support: Balanced nutrition, with avoidance of alcohol.

Avoid hepatotoxic drugs: Such as NSAIDs and paracetamol in excessive doses.

b) Specific Antiviral Therapy:

Hepatitis A and E: No specific antiviral therapy is available; treatment is supportive. Both viruses are usually self-limiting.

Hepatitis B:

Acute hepatitis B: Supportive care is usually sufficient.

Chronic hepatitis B: Antiviral therapy is recommended to suppress viral replication and prevent progression to cirrhosis or hepatocellular carcinoma. First-line drugs include **tenofovir** and **entecavir**.

Hepatitis C:

Direct-acting antivirals (DAAs) are used for **chronic hepatitis C**. These drugs (e.g., **sofosbuvir**, **ledipasvir**) have high cure rates and are usually well-tolerated.

Hepatitis D: Treatment focuses on **controlling hepatitis B**, as hepatitis D requires hepatitis B to replicate. **Interferon therapy** is sometimes used.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Corticosteroids are contraindicated in viral hepatitis as they may worsen the course of the disease.

b) Second-Line Therapy:

For patients with chronic **hepatitis B** or **C** not responding to standard antiviral therapy, newer DAAs or a combination of drugs may be used.

Liver transplantation may be necessary in patients with **fulminant hepatic failure** or end-stage liver disease due to chronic viral hepatitis.

8. Routine Monitoring and Follow-Up:

Liver function tests: Regular monitoring of ALT, AST, and bilirubin to assess liver function.

Viral load testing: Periodic **PCR testing** to monitor viral replication in chronic hepatitis B or C.

Ultrasound and FibroScan: Monitoring for the development of fibrosis or cirrhosis.

Hepatocellular carcinoma (HCC) screening: In patients with chronic hepatitis B or C and cirrhosis, **ultrasound** and **alpha-fetoprotein (AFP)** levels should be monitored every 6 months for early detection of HCC.

9. Complications of Viral Hepatitis:

Fulminant hepatitis: Rare but life-threatening, characterised by severe liver failure and encephalopathy.

Chronic hepatitis: Prolonged inflammation can lead to **fibrosis**, **cirrhosis**, and eventually **liver failure**.

Hepatocellular carcinoma (HCC): Chronic hepatitis B and C increase the risk of liver cancer.

Portal hypertension: Caused by cirrhosis, leading to ascites, varices, and splenomegaly.

Extrahepatic manifestations: Particularly in hepatitis B and C, such as **glomerulonephritis**, **vasculitis**, and **cryoglobulinaemia**.

Summary of Key Points for Viral Hepatitis:

Viral hepatitis is liver inflammation caused by specific hepatotropic viruses (hepatitis A, B, C, D, and E).

Common symptoms include jaundice, fatigue, RUQ pain, and dark urine.

Diagnosis is based on **clinical presentation**, **LFTs**, and **viral serology**.

Antiviral therapy is essential for **chronic hepatitis B and C** to prevent progression to cirrhosis and liver cancer.

Complications include **fulminant liver failure**, **cirrhosis**, and **hepatocellular carcinoma**.

195. Autoimmune Hepatitis

1. Detailed Definition of Autoimmune Hepatitis:

Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease characterized by **immune-mediated destruction of hepatocytes**. It occurs when the body's immune system mistakenly attacks the liver, leading to inflammation, fibrosis, and potentially cirrhosis if left untreated. AIH is often associated with other **autoimmune disorders** such as **rheumatoid arthritis**, **type 1 diabetes**, and **thyroid disease**. The disease can present at any age but typically affects **women more than men** (70-80% of cases).

2. Common Presenting Complaints and Symptoms:

The presentation of autoimmune hepatitis can range from **asymptomatic** to **severe liver failure**. Common symptoms include:

Fatigue: The most common symptom.

Jaundice: Yellowing of the skin and eyes, caused by elevated bilirubin levels.

Right upper quadrant (RUQ) pain: Due to liver inflammation.

Pruritus: Itching, secondary to cholestasis.

Arthralgia: Joint pain, particularly in the small joints of the hands and wrists.

Fever: Low-grade fever can occur.

Hepatomegaly: Enlarged liver, palpable on examination.

Nausea and vomiting.

Menstrual irregularities: Common in women, possibly due to hormonal changes related to liver dysfunction.

Signs of chronic liver disease: Including spider naevi, palmar erythema, and ascites in more advanced cases.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated ALT and AST: Indicative of hepatocellular injury, often > 3-4 times the upper limit of normal.

Bilirubin: Raised in more severe cases, leading to jaundice.

Alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT): May be mildly elevated, though typically less so than in cholestatic liver diseases.

Albumin: Low in advanced disease due to impaired synthetic function.

Prothrombin time (PT)/INR: Prolonged in severe or advanced disease due to impaired production of clotting factors.

Autoantibody tests:

Antinuclear antibodies (ANA): Positive in up to 80% of cases.

Smooth muscle antibodies (SMA): Present in about 70-80% of patients.

Liver/kidney microsomal antibody type 1 (anti-LKM1): Found in around 10% of cases, especially in type 2 AIH.

Anti-soluble liver antigen/liver-pancreas antigen (anti-SLA/LP): May also be present.

Immunoglobulins:

Serum IgG: Elevated in more than 85% of patients with AIH.

Full blood count (FBC): May reveal **anaemia**, **thrombocytopaenia**, or **leucopaenia**, often seen in advanced disease or cirrhosis.

b) Imaging:

Abdominal Ultrasound:

Performed to assess **liver size**, **texture**, and exclude other causes of liver disease such as biliary obstruction or cirrhosis.

Liver FibroScan:

Non-invasive method of assessing **liver stiffness**, used to evaluate for **fibrosis** or **cirrhosis**.

c) Special Tests:

Liver biopsy:

Gold standard for diagnosing autoimmune hepatitis. It reveals **interface hepatitis**, **plasma cell infiltrates**, and varying degrees of fibrosis.

Used to confirm diagnosis, assess disease severity, and monitor response to treatment.

4. Explanation of Investigations:

Autoantibodies: The presence of **ANA**, **SMA**, and **anti-LKM1** supports the diagnosis of autoimmune hepatitis.

Serum IgG: Elevated IgG levels are a hallmark of AIH, suggesting immune activation.

Liver biopsy: Provides definitive histological evidence of inflammation and fibrosis, essential for confirming the diagnosis and guiding treatment.

5. Diagnosis Criteria for Autoimmune Hepatitis:

The diagnosis of AIH is based on:

Clinical features: Fatigue, jaundice, RUQ pain, and signs of chronic liver disease.

Laboratory findings:

Elevated **ALT/AST**, **bilirubin**, and **IgG**.

Positive **autoantibodies** (ANA, SMA, anti-LKM1).

Liver biopsy: Histological confirmation of **interface hepatitis**, **plasma cell infiltration**, and **fibrosis**.

The **International Autoimmune Hepatitis Group (IAIHG)** scoring system can be used to confirm the diagnosis. It incorporates clinical, serological, and histological findings.

6. First-Line Therapy According to Guidelines:

The goal of treatment is to **suppress the immune system**, reduce liver inflammation, and prevent progression to cirrhosis.

a) Corticosteroids:

Prednisolone:

First-line treatment for AIH, typically starting at **30-40 mg/day**, and gradually tapering over weeks to months based on clinical response and LFTs.

It reduces inflammation by inhibiting immune cell activation.

b) Immunosuppressants:

Azathioprine:

Usually added as a **steroid-sparing agent** (50-150 mg/day), allowing for lower doses of corticosteroids and minimising side effects.

Mechanism: Azathioprine suppresses T-cell activation and proliferation, helping to control the autoimmune response.

c) Combination Therapy:

A combination of **prednisolone** and **azathioprine** is often initiated early in treatment to achieve remission while reducing steroid dependency.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Corticosteroids should be used with caution in patients with poorly controlled diabetes, osteoporosis, or infections due to the risk of exacerbating these conditions.

b) Second-Line Therapy:

Mycophenolate mofetil, cyclosporine, or tacrolimus may be used if patients are **intolerant to azathioprine** or **resistant to standard therapy**.

Liver transplantation: Considered in patients with **end-stage liver disease** or **acute liver failure** due to AIH, or those who fail to respond to medical treatment.

8. Routine Monitoring and Follow-Up:

Liver function tests: Regular monitoring of **ALT, AST, bilirubin**, and **albumin** to assess response to treatment.

Autoantibody titres: Can be monitored over time, but they do not always correlate directly with disease activity.

Bone density scans: Long-term corticosteroid use increases the risk of **osteoporosis**; therefore, regular bone density assessments are recommended.

Immunosuppressant monitoring: Regular **FBC** and **liver tests** to monitor for side effects of **azathioprine** or second-line immunosuppressants.

9. Complications of Autoimmune Hepatitis:

Cirrhosis: AIH can progress to cirrhosis if left untreated or if treatment fails.

Hepatocellular carcinoma (HCC): Patients with cirrhosis due to AIH are at increased risk for developing liver cancer.

Osteoporosis: Long-term corticosteroid use increases the risk of bone loss and fractures.

Portal hypertension: Secondary to cirrhosis, leading to complications such as ascites, varices, and splenomegaly.

Drug toxicity: From long-term immunosuppressive therapy, leading to bone marrow suppression or increased infection risk.

Summary of Key Points for Autoimmune Hepatitis:

Autoimmune hepatitis (AIH) is an immune-mediated chronic liver disease that can progress to cirrhosis if left untreated.

Common symptoms include fatigue, jaundice, RUQ pain, and signs of chronic liver disease.

Diagnosis is based on **autoantibody positivity**, **elevated IgG**, and **liver biopsy** showing interface hepatitis and plasma cell infiltrates.

First-line treatment is **prednisolone** combined with **azathioprine** to reduce liver inflammation and prevent disease progression.

Complications include progression to **cirrhosis**, **hepatocellular carcinoma**, and the side effects of long-term immunosuppressive therapy.

196. Drug-Induced Hepatitis

1. Detailed Definition of Drug-Induced Hepatitis:

Drug-induced hepatitis refers to **liver inflammation** caused by a reaction to certain medications, toxins, or herbal supplements. It is a subset of **drug-induced liver injury (DILI)** and can range from mild, asymptomatic liver enzyme elevations to severe **acute liver failure**. Drug-induced hepatitis is a **reversible condition** if recognised early and the offending drug is discontinued, but it can lead to **chronic liver disease** or death if not managed promptly.

2. Common Presenting Complaints and Symptoms:

The presentation of drug-induced hepatitis can vary, depending on the severity and duration of the injury. Symptoms can range from **asymptomatic** elevations in liver enzymes to **acute liver failure**. Common symptoms include:

Fatigue and malaise: Nonspecific symptoms.

Jaundice: Yellowing of the skin and eyes due to elevated bilirubin levels.

Nausea, vomiting, and anorexia: Common GI symptoms.

Right upper quadrant (RUQ) pain: Caused by liver inflammation.

Dark urine and pale stools: Associated with cholestasis.

Fever: In some cases, especially if the injury is immune-mediated.

Pruritus: Itching, due to bile salt retention.

In severe cases:

Ascites: Fluid accumulation in the abdomen.

Hepatic encephalopathy: Confusion and altered mental status due to liver failure.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

Elevated ALT and AST: Suggest hepatocellular damage, often with ALT levels higher than AST.

Bilirubin: Elevated in more severe cases, causing jaundice.

Alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT): Elevated if there is cholestasis.

Albumin: Decreased in chronic or severe liver injury.

Prothrombin time (PT)/INR: Prolonged in severe cases due to impaired synthesis of clotting factors.

Full blood count (FBC):

May show **eosinophilia** in cases of hypersensitivity reactions or **thrombocytopenia** in severe liver disease.

Urea and electrolytes:

To assess renal function and detect complications like hepatorenal syndrome.

Serum drug levels:

For some drugs (e.g., **paracetamol, valproate**), serum levels can be measured to assess toxicity.

b) Imaging:

Abdominal Ultrasound:

Performed to assess **liver size**, exclude **biliary obstruction**, and check for complications such as **ascites** or **hepatic masses**.

c) Special Tests:

Liver biopsy:

Rarely performed but can be helpful in unclear cases to assess the pattern of liver injury (e.g., **hepatocellular**, **cholestatic**, or **mixed**).

Histology: May show **hepatocyte necrosis**, **inflammation**, or **steatosis** depending on the drug involved.

4. Explanation of Investigations:

LFTs: Elevated **ALT** and **AST** suggest hepatocellular injury, while elevated **ALP** and **GGT** indicate cholestasis. **Bilirubin** may be raised in cases of cholestatic or hepatocellular injury.

Liver biopsy: Used when the diagnosis is unclear or to confirm drug-induced liver injury when other causes have been excluded.

5. Diagnosis Criteria for Drug-Induced Hepatitis:

The diagnosis of drug-induced hepatitis is made based on:

History: A detailed history of drug use is essential. Common medications associated with drug-induced hepatitis include:

Paracetamol (acetaminophen): The most common cause of drug-induced liver injury, particularly in overdose.

Antibiotics: E.g., **amoxicillin-clavulanate**, **isoniazid**, **rifampicin**, **tetracyclines**.

Nonsteroidal anti-inflammatory drugs (NSAIDs): E.g., **diclofenac**, **ibuprofen**.

Antiepileptic drugs: E.g., **valproate**, **phenytoin**, **carbamazepine**.

Statins, **methotrexate**, **anabolic steroids**, and **herbal supplements** (e.g., **green tea extract**, **kava**).

Laboratory findings:

Elevated **ALT/AST** (hepatocellular injury), **ALP/GGT** (cholestatic injury), or both (mixed injury).

Serum drug levels for certain drugs (e.g., paracetamol) can confirm overdose or toxicity.

Exclusion of other causes:

Rule out **viral hepatitis** (e.g., hepatitis A, B, C, E), **alcoholic liver disease**, and **autoimmune hepatitis**.

Negative serology and history of alcohol intake help to exclude other causes.

Liver biopsy: Rarely required but can confirm the diagnosis when other investigations are inconclusive.

6. First-Line Therapy According to Guidelines:

a) Immediate Discontinuation of the Offending Drug:

Stop the drug that is causing liver injury as soon as drug-induced hepatitis is suspected.

b) Supportive Therapy:

Fluid replacement: To maintain hydration and prevent renal dysfunction, particularly in severe cases of liver injury.

Nutritional support: Balanced nutrition is essential, especially in cases of chronic liver damage.

Monitoring: Regular monitoring of **LFTs, renal function, and INR** to assess for liver recovery.

c) Specific Antidotes:

Paracetamol overdose:

Administer **N-acetylcysteine (NAC)** as soon as possible, even in late-presenting cases, to prevent or reduce liver damage.

Valproate toxicity:

Consider **carnitine** administration in cases of valproate-induced liver injury.

Steroids:

In cases of severe drug-induced liver injury with hypersensitivity reactions (e.g., eosinophilia, rash), **corticosteroids** may be used.

d) Liver Transplantation:

In cases of **acute liver failure** due to drug-induced hepatitis, liver transplantation may be the only life-saving option.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Re-challenging with the offending drug should be avoided, as this can lead to severe, often fatal, liver injury.

b) Second-Line Therapy:

In cases where the cause of liver injury is unclear, **other medications** with a lower risk of hepatotoxicity should be considered for the treatment of the patient's underlying condition.

8. Routine Monitoring and Follow-Up:

Liver function tests:

Regular monitoring of **ALT, AST, bilirubin, and INR** is essential to assess recovery after stopping the drug.

Serial blood tests:

For drugs like **methotrexate** or **isoniazid**, regular monitoring of **LFTs** during treatment is critical to detect early liver injury.

Imaging:

Ultrasound or **FibroScan** may be needed to assess for **fibrosis** or **cirrhosis** in chronic or severe cases of drug-induced hepatitis.

9. Complications of Drug-Induced Hepatitis:

Acute liver failure: May result in hepatic encephalopathy, coagulopathy, and multi-organ failure, requiring urgent liver transplantation.

Chronic hepatitis: Some cases of drug-induced hepatitis can progress to chronic liver disease and cirrhosis if the drug is not stopped promptly.

Cirrhosis: Long-term damage from chronic drug-induced hepatitis can lead to cirrhosis.

Portal hypertension: Secondary to cirrhosis, leading to ascites, varices, and splenomegaly.

Summary of Key Points for Drug-Induced Hepatitis:

Drug-induced hepatitis is caused by medications, toxins, or supplements that damage the liver.

Common presenting symptoms include **fatigue**, **jaundice**, **RUQ pain**, and **nausea**.

Diagnosis is based on a detailed **drug history**, elevated **LFTs**, and exclusion of other causes of liver disease.

First-line treatment is the immediate discontinuation of the offending drug, along with supportive care.

Antidotes (e.g., **N-acetylcysteine** for paracetamol overdose) should be used where applicable.

Complications include progression to **acute liver failure**, **chronic hepatitis**, and **cirrhosis**.

197. Ascites

1. Detailed Definition of Ascites:

Ascites refers to the abnormal accumulation of fluid in the **peritoneal cavity**, often due to **portal hypertension** secondary to **chronic liver disease** (e.g., cirrhosis). It can also be caused by other conditions such as **heart failure**, **malignancy**, **nephrotic syndrome**, and **infections** like **tuberculosis**. Ascites is the most common complication of **cirrhosis** and indicates advanced liver disease.

2. Common Presenting Complaints and Symptoms:

Patients with ascites may present with a range of symptoms, depending on the underlying cause and the amount of fluid accumulation:

Abdominal distension: The most common symptom due to fluid buildup.

Weight gain: Unintentional, due to fluid retention.

Shortness of breath: Resulting from pressure on the diaphragm, particularly in severe ascites.

Early satiety: Feeling full quickly due to increased abdominal pressure.

Discomfort or pain: As the abdomen becomes stretched.

Bloating and indigestion.

Peripheral oedema: Swelling of the legs and ankles may accompany ascites.

Signs of underlying liver disease: Jaundice, spider naevi, palmar erythema, and encephalopathy in patients with cirrhosis.

3. First-Line Investigations:

a) Blood Tests:

Liver function tests (LFTs):

To assess the underlying cause, particularly liver disease.

Elevated **ALT**, **AST**, **bilirubin**, and **ALP** may indicate liver dysfunction.

Serum albumin: Usually low in cirrhosis and nephrotic syndrome, leading to hypoalbuminaemia.

Prothrombin time (PT)/INR: Prolonged in severe liver disease due to impaired production of clotting factors.

Urea and electrolytes (U&Es): To assess renal function and detect hyponatraemia, which is common in cirrhosis.

Serum creatinine: To check for renal impairment, which may suggest hepatorenal syndrome in cirrhosis.

b) Imaging:

Abdominal Ultrasound:

The first-line imaging modality to confirm the presence of ascites and assess liver size, structure, and other possible causes, such as **hepatic tumours** or **portal vein thrombosis**.

It can detect small amounts of fluid and provide guidance for **paracentesis**.

c) Special Tests:

Diagnostic Paracentesis:

Gold standard for determining the cause of ascites. A sample of ascitic fluid is obtained and tested for:

Appearance: Cloudy fluid suggests infection (e.g., spontaneous bacterial peritonitis).

White cell count: A polymorphonuclear leukocyte count > 250 cells/ μL suggests spontaneous bacterial peritonitis (SBP).

Serum-ascites albumin gradient (SAAG): Helps to differentiate causes of ascites:

High SAAG (> 1.1 g/dL): Indicates portal hypertension (e.g., cirrhosis, heart failure).

Low SAAG (< 1.1 g/dL): Suggests non-portal hypertension causes (e.g., malignancy, nephrotic syndrome, tuberculosis).

Culture and sensitivity: To identify bacterial infection.

Cytology: To check for malignant cells in suspected malignant ascites.

Protein: Low protein in cirrhotic ascites (< 2.5 g/dL) and higher in cardiac ascites or malignancy (> 2.5 g/dL).

CT Scan:

Used to evaluate underlying causes like **abdominal malignancies, portal vein thrombosis, or pancreatic diseases.**

4. Explanation of Investigations:

SAAG (Serum-Ascites Albumin Gradient): This test is key to identifying whether ascites is due to portal hypertension. A gradient > 1.1 g/dL suggests portal hypertension as seen in cirrhosis, while a gradient < 1.1 g/dL suggests other causes such as peritoneal carcinomatosis or nephrotic syndrome.

Ultrasound: Helps confirm fluid accumulation and evaluate liver size and structure.

Paracentesis: Essential for diagnosing infection (e.g., SBP) and ruling out malignant or tuberculous ascites.

5. Diagnosis Criteria for Ascites:

Diagnosis is based on:

Clinical features: Abdominal distension, weight gain, and discomfort.

Ultrasound confirmation: Showing free fluid in the peritoneal cavity.

Paracentesis:

SAAG > 1.1 g/dL indicates **portal hypertension.**

Polymorphonuclear count > 250 cells/ μL indicates **spontaneous bacterial peritonitis (SBP).**

6. First-Line Therapy According to Guidelines:

a) Management of Cirrhotic Ascites:

Salt restriction:

A low-sodium diet (typically < **2g/day**) is recommended to reduce fluid accumulation.

Diuretics:

Spironolactone: First-line diuretic, starting at 100 mg/day, titrated up to a maximum of 400 mg/day. It works by antagonising aldosterone, which helps reduce sodium and water retention.

Furosemide: Often added to spironolactone, starting at 40 mg/day, titrated up to 160 mg/day, to further enhance diuresis.

Paracentesis:

Therapeutic paracentesis is indicated for **tense ascites** or symptomatic relief in patients with large-volume ascites.

Albumin infusion is recommended when more than **5 litres** of ascitic fluid are removed to prevent **post-paracentesis circulatory dysfunction** (8 g/L of fluid removed).

b) Treat Underlying Cause:

Cirrhosis: If due to cirrhosis, management focuses on treating underlying liver disease (e.g., alcohol abstinence, antiviral therapy for hepatitis B/C).

Heart failure: Treat the underlying cardiac cause with diuretics, ACE inhibitors, or beta-blockers.

Malignancy: In cases of malignant ascites, chemotherapy or surgery may be indicated.

Nephrotic syndrome: Treat with diuretics and manage the underlying kidney disease.

7. Common Contraindications and Second-Line Therapy:**a) Contraindications:**

Diuretics are contraindicated in patients with **hepatorenal syndrome** or those who develop **electrolyte imbalances** (e.g., severe hyponatraemia or hyperkalaemia).

b) Second-Line Therapy:**Transjugular Intrahepatic Portosystemic Shunt (TIPS):**

Considered in patients with **refractory ascites** who do not respond to diuretics or frequent paracentesis.

TIPS decreases portal pressure by creating a shunt between the portal and systemic circulation.

Liver transplantation:

The definitive treatment for **refractory ascites** in patients with **end-stage liver disease**.

8. Routine Monitoring and Follow-Up:

Regular monitoring of electrolytes and renal function:

Urea and electrolytes should be monitored regularly during diuretic therapy to prevent electrolyte imbalances and renal impairment.

Weight and abdominal girth:

Daily weight monitoring and abdominal girth measurement to assess response to diuretics and fluid management.

Surveillance for complications:

Monitor for the development of **spontaneous bacterial peritonitis (SBP)**, which requires prompt treatment with antibiotics (e.g., **intravenous cefotaxime**).

9. Complications of Ascites:

Spontaneous bacterial peritonitis (SBP): A life-threatening complication of ascites, especially in cirrhotic patients, caused by infection of the ascitic fluid. It presents with fever, abdominal pain, and altered mental status.

Hepatorenal syndrome: Progressive renal failure in patients with advanced liver disease and ascites.

Respiratory compromise: Due to large-volume ascites compressing the diaphragm.

Malnutrition: Patients with ascites often have poor nutritional intake due to early satiety.

Umbilical hernia: Increased intra-abdominal pressure from ascites may lead to hernia formation.

Summary of Key Points for Ascites:

Ascites is the accumulation of fluid in the peritoneal cavity, most commonly due to **cirrhosis** and **portal hypertension**.

Common symptoms include abdominal distension, discomfort, and weight gain.

Diagnosis is confirmed by **ultrasound** and **paracentesis**, with SAAG used to differentiate causes.

198. Haemochromatosis

1. Detailed Definition of Haemochromatosis:

Haemochromatosis is a genetic disorder characterised by excessive absorption and accumulation of **iron** in various organs, primarily the **liver, heart, pancreas, and joints**. This leads to **organ damage** due to iron toxicity. **Hereditary haemochromatosis (HH)** is the most common form and is usually caused by mutations in the **HFE gene**. The disorder is more common in people of **Northern European descent**, with an onset typically in **middle age**.

2. Common Presenting Complaints and Symptoms:

Symptoms of haemochromatosis vary depending on the degree of iron overload and the organs affected. Early-stage haemochromatosis can be asymptomatic or present with non-specific symptoms. Common symptoms include:

Fatigue and lethargy: The most common early symptom.

Joint pain: Particularly affecting the **knuckles, wrists, knees, and ankles** (often the **second and third metacarpophalangeal joints**).

Bronze skin pigmentation: Due to increased melanin production and iron deposition ("**bronze diabetes**").

Diabetes mellitus: Iron deposition in the pancreas can lead to **diabetes** (hence the term "bronze diabetes").

Liver disease: Ranging from **hepatomegaly** to **cirrhosis** in advanced cases.

Loss of libido and impotence: Due to hypogonadism and pituitary iron deposition.

Cardiomyopathy: Manifesting as **heart failure** or **arrhythmias** in severe iron overload.

Abdominal pain: Commonly in the upper right quadrant due to liver involvement.

3. First-Line Investigations:

a) Blood Tests:

Serum Ferritin:

Elevated ferritin is the most sensitive test for iron overload. However, it is also an acute-phase reactant and can be elevated in **inflammation, infection, or malignancy**.

Transferrin saturation:

The ratio of **serum iron** to **total iron-binding capacity (TIBC)**. A transferrin saturation of **>45%** is highly suggestive of haemochromatosis.

Liver function tests (LFTs):

To assess liver damage, with **elevated ALT and AST** indicating hepatocellular injury. **Elevated bilirubin** and **albumin** levels may suggest advanced liver disease or cirrhosis.

Genetic testing:

HFE gene mutation analysis is the definitive test for hereditary haemochromatosis. The **C282Y** mutation is the most common, and individuals who are **homozygous** for this mutation are at the highest risk of developing haemochromatosis.

H63D mutation is less commonly associated with significant iron overload.

b) Imaging:

Abdominal Ultrasound:

Used to assess liver size and texture, and to detect **cirrhosis** or **hepatocellular carcinoma (HCC)**.

MRI:

Liver MRI is a sensitive, non-invasive method to quantify **iron overload** in the liver and assess for iron deposition in other organs such as the heart.

c) Special Tests:

Liver Biopsy:

Rarely required but may be used to confirm the diagnosis and assess the degree of fibrosis or cirrhosis in unclear cases. **Liver biopsy** is indicated when there is uncertainty about the degree of liver involvement, or if ferritin levels are >1,000 ng/mL.

Perl's stain can be used to detect **iron deposits** within hepatocytes.

4. Explanation of Investigations:

Serum ferritin: A marker of iron stores in the body. High levels indicate iron overload but can be falsely elevated in conditions like inflammation or infection.

Transferrin saturation: Measures the percentage of transferrin that is saturated with iron. Elevated levels (>45%) are highly suggestive of iron overload in haemochromatosis.

Genetic testing: Confirms the diagnosis by identifying mutations in the **HFE gene**, particularly **C282Y homozygosity**.

5. Diagnosis Criteria for Haemochromatosis:

The diagnosis of hereditary haemochromatosis is made based on:

Clinical features: Fatigue, joint pain, bronze skin pigmentation, and signs of liver or heart disease.

Laboratory findings:

Elevated ferritin and **transferrin saturation >45%**.

Genetic testing showing **C282Y homozygosity** or **compound heterozygosity** for C282Y/H63D.

Liver biopsy or **MRI:** To assess iron deposition in the liver, particularly in unclear cases or when the diagnosis is not confirmed through genetic testing.

6. First-Line Therapy According to Guidelines:

a) Phlebotomy (Venesection):

First-line treatment for reducing iron levels in hereditary haemochromatosis.

Weekly phlebotomy is performed, with each session typically removing **500 mL of blood** (equivalent to 200-250 mg of iron).

The aim is to reduce serum **ferritin to <50 µg/L** and **transferrin saturation <50%**.

Maintenance phlebotomy (every 2-3 months) is usually required once iron levels are controlled.

b) Iron Chelation Therapy:

Deferasirox or **deferoxamine** may be used in patients who are **unable to tolerate phlebotomy**, such as those with anaemia or heart failure.

These drugs bind to excess iron, allowing it to be excreted in urine or faeces.

c) Lifestyle Modifications:

Avoid alcohol: Alcohol consumption can accelerate liver damage in haemochromatosis.

Avoid iron supplements and **vitamin C supplements:** Vitamin C increases iron absorption and can worsen iron overload.

Healthy diet: Avoid excessive intake of red meat, which is rich in haem iron.

7. Common Contraindications and Second-Line Therapy:

a) Contraindications:

Phlebotomy is contraindicated in patients with **severe anaemia** or conditions such as **heart failure**, where reducing blood volume may cause further decompensation.

b) Second-Line Therapy:

Iron chelation therapy is used when phlebotomy is not possible. **Deferasirox** and **deferoxamine** bind iron and promote its excretion.

Liver transplantation may be indicated in patients who develop **end-stage liver disease** or **hepatocellular carcinoma** due to iron overload.

8. Routine Monitoring and Follow-Up:

Regular monitoring of ferritin and transferrin saturation:

Ferritin levels should be checked every **3-4 months** during phlebotomy treatment, and **every 6-12 months** once maintenance phlebotomy is established.

Liver function tests:

LFTs should be monitored regularly, particularly in patients with cirrhosis, to assess for liver damage and monitor for the development of complications such as **hepatocellular carcinoma (HCC)**.

Ultrasound and MRI:

Liver ultrasound and **AFP (alpha-fetoprotein)** should be monitored every **6-12 months** in patients with cirrhosis for early detection of HCC.

9. Complications of Haemochromatosis:

Cirrhosis: Chronic liver damage due to iron overload can lead to fibrosis and cirrhosis.

Hepatocellular carcinoma (HCC): Patients with cirrhosis due to haemochromatosis are at increased risk for developing liver cancer.

Diabetes mellitus: Iron deposition in the pancreas can lead to diabetes ("**bronze diabetes**").

Heart disease: Iron accumulation in the myocardium can cause **cardiomyopathy**, leading to heart failure and arrhythmias.

Arthropathy: Joint pain, particularly in the hands and wrists, is common in haemochromatosis.

Hypogonadism: Iron overload in the pituitary gland can lead to **hypogonadism**, resulting in reduced libido and erectile dysfunction.

Summary of Key Points for Haemochromatosis:

Haemochromatosis is a genetic disorder characterised by excessive iron absorption and accumulation in organs such as the liver, heart, and pancreas.

Common symptoms include fatigue, joint pain, bronze skin pigmentation, diabetes, and signs of liver disease.

Diagnosis is based on **elevated serum ferritin**, **transferrin saturation >45%**, and **genetic testing** showing mutations in the **HFE gene**.

199. Hepatocellular Carcinoma (HCC) and Liver Metastasis

1. Detailed Definition

Hepatocellular Carcinoma (HCC):

Hepatocellular carcinoma (HCC) is the most common type of **primary liver cancer**, arising from **hepatocytes**. It is most often associated with **chronic liver disease** and **cirrhosis**, particularly in patients with **hepatitis B**, **hepatitis C**, **alcoholic liver disease**, or **non-alcoholic fatty liver disease (NAFLD)**. HCC has a poor prognosis if diagnosed late, making **early detection** critical.

Liver Metastasis:

Liver metastasis refers to **secondary cancer** that has spread to the liver from another **primary tumour** located elsewhere in the body. Common primary sources of liver metastasis include **colorectal cancer**, **breast cancer**, **lung cancer**, **pancreatic cancer**, and **melanoma**. The liver is a common site for metastasis due to its rich blood supply and dual circulation from the **hepatic artery** and **portal vein**.

2. Common Presenting Complaints and Symptoms

Hepatocellular Carcinoma (HCC):

Weight loss and **anorexia**: Unintentional weight loss is common in advanced disease.

Abdominal pain: Particularly in the **right upper quadrant (RUQ)**, due to liver enlargement or tumour growth.

Jaundice: Caused by tumour-induced bile duct obstruction or advanced liver disease.

Ascites: Fluid accumulation in the abdomen, often due to cirrhosis or portal hypertension.

Fatigue: Often associated with liver dysfunction and general cancer-related fatigue.

Hepatomegaly: The liver may feel enlarged on palpation due to the tumour.

Fever: Occasionally seen in HCC.

Signs of chronic liver disease: Spider naevi, palmar erythema, and splenomegaly.

Liver Metastasis:

Abdominal discomfort or pain: Generally diffuse and can worsen as the liver enlarges.

Weight loss and fatigue: Common in metastatic cancer.

Hepatomegaly: The liver may be enlarged on physical examination.

Jaundice: Less common than in HCC, but can occur if large metastases obstruct bile ducts.

Ascites: Due to liver involvement or portal hypertension.

3. First-Line Investigations

a) Blood Tests:

Liver function tests (LFTs):

Elevated **ALT**, **AST**, and **bilirubin** suggest liver involvement.

ALP and **GGT** are often raised, particularly in cholestasis or bile duct involvement.

Alpha-fetoprotein (AFP):

A tumour marker commonly elevated in HCC, though it may also be elevated in other liver diseases or some metastatic cancers.

CEA and CA 19-9:

Useful for assessing primary tumours such as colorectal or pancreatic cancer with liver metastasis.

b) Imaging:

Ultrasound:

Initial imaging modality to assess for liver masses.

Can guide **biopsy** if necessary.

Triphasic CT Scan or MRI:

Gold standard for assessing liver lesions and determining the extent of tumour invasion in HCC and liver metastasis.

Arterial-phase enhancement on CT is characteristic of HCC.

Helps differentiate **benign** from **malignant** liver lesions and detect metastases.

PET-CT Scan:

Used for detecting metastatic disease, staging cancers, and assessing for extra-hepatic metastasis.

c) Special Tests:

Liver biopsy:

Rarely required for HCC if imaging findings are characteristic and AFP levels are elevated. However, biopsy is often performed to confirm the diagnosis in cases of **liver metastasis**.

4. Explanation of Investigations

AFP: Elevated in up to 70% of patients with HCC. However, not all cases of HCC show elevated AFP, so imaging is crucial.

Liver biopsy: Provides a histopathological diagnosis of HCC or liver metastasis and helps confirm the primary tumour in cases of metastasis.

Triphasic CT or MRI: The contrast phases highlight arterial and venous blood flow, helping to characterise HCC and liver metastases based on their vascularity.

5. Diagnosis Criteria

Hepatocellular Carcinoma (HCC):

Imaging findings:

Arterial enhancement and **venous washout** on **triphasic CT** or **MRI** are characteristic of HCC.

AFP levels:

AFP > **400 ng/mL** is strongly suggestive of HCC, especially in the context of liver disease.

Biopsy:

Liver biopsy is not always necessary if imaging and AFP levels are conclusive. However, biopsy can be done to confirm atypical cases.

Liver Metastasis:

Imaging findings:

Multiple lesions on **CT** or **MRI**, often hypovascular (unless from primary cancers like renal cell carcinoma or neuroendocrine tumours).

Histology:

Biopsy of the liver lesion to confirm metastasis and determine the primary tumour source if not known.

Tumour markers:

Tumour markers (e.g., **CEA**, **CA 19-9**) help identify the primary tumour in cases of liver metastasis from colorectal or pancreatic cancer.

6. First-Line Therapy According to Guidelines

a) Hepatocellular Carcinoma (HCC):

Surgical resection:

Curative option for early-stage HCC (Barcelona Clinic Liver Cancer [BCLC] stage A).

Liver transplantation is an option for patients with early-stage HCC who are not surgical candidates.

Ablation therapies:

Radiofrequency ablation (RFA) or **microwave ablation** are used for small tumours (<3 cm), particularly for patients who are not surgical candidates.

Transarterial chemoembolisation (TACE):

Used for **intermediate-stage HCC** or as a bridge to surgery or transplantation.

Involves delivering chemotherapy directly into the hepatic artery feeding the tumour, combined with embolic agents to block blood flow.

Systemic therapy:

Sorafenib (a tyrosine kinase inhibitor) is used in **advanced HCC** (BCLC stage C) and unresectable cases.

Atezolizumab + bevacizumab: An immunotherapy regimen showing promising results in advanced HCC.

b) Liver Metastasis:

Surgical resection:

Hepatic resection can be curative in select patients with limited liver metastasis, particularly from **colorectal cancer**.

Systemic chemotherapy:

For metastatic disease, chemotherapy is often required, tailored to the primary cancer (e.g., **FOLFOX** or **FOLFIRI** for colorectal cancer).

Radiofrequency ablation (RFA):

Used for local control in patients who are not candidates for surgical resection.

Targeted therapy and immunotherapy:

Depending on the primary cancer, therapies such as **targeted therapies** (e.g., **bevacizumab** for colorectal cancer) or **checkpoint inhibitors** (e.g., pembrolizumab for melanoma) may be used.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery is contraindicated in patients with **poor liver function**, advanced cirrhosis, or significant extrahepatic disease.

TACE is not recommended in patients with **decompensated liver disease** (e.g., Child-Pugh class C).

b) Second-Line Therapy:

Second-line systemic therapies for HCC include **lenvatinib**, **regorafenib**, or **cabozantinib** if sorafenib or immunotherapy fails.

Systemic chemotherapy for liver metastasis may be adjusted depending on tumour response or progression.

8. Routine Monitoring and Follow-Up

Surveillance imaging:

For patients with cirrhosis or known risk factors for HCC, **ultrasound** every **6 months** with or without **AFP** is recommended to detect early-stage HCC.

Follow-up imaging:

After treatment for HCC or liver metastasis, regular **CT** or **MRI** scans are used to monitor for recurrence or progression.

AFP and LFT monitoring:

Serial measurements of **AFP** and **LFTs** help assess response to treatment and detect recurrence in patients with HCC.

9. Complications

Hepatocellular Carcinoma (HCC):

Portal vein thrombosis: Tumour invasion of the portal vein leading to increased portal hypertension.

Hepatic encephalopathy: Due to liver failure in advanced disease.

Metastasis: Most commonly to the lungs, bones, and adrenal glands.

Liver Metastasis:

Obstructive jaundice: Due to large metastases blocking the bile ducts.

Hepatic failure: Occurs when a large proportion of the liver is involved in metastatic disease.

Summary of Key Points

Hepatocellular carcinoma (HCC) is a primary liver cancer associated with chronic liver disease and cirrhosis, whereas **liver metastasis** is secondary cancer from another primary site.

Common symptoms include abdominal pain, weight loss, and jaundice.

Diagnosis is based on **imaging** (CT/MRI), **tumour markers** (e.g., AFP for HCC), and sometimes biopsy.

First-line treatments include **surgical resection**, **ablation**, **TACE**, and **systemic therapies** for HCC. For liver metastasis, systemic chemotherapy and resection may be curative.

200. Metastatic Disease

1. Detailed Definition of Metastatic Disease

Metastatic disease refers to the spread of **cancer** from its site of origin (**primary tumour**) to distant organs or tissues, forming **secondary tumours**. The process of metastasis involves **cancer cells detaching** from the primary tumour, entering the bloodstream or lymphatic system, and establishing new tumours in organs such as the **lungs**, **liver**, **bones**, and **brain**. Metastatic disease is often a sign of **advanced cancer** and is associated with a poorer prognosis compared to localised cancer.

2. Common Presenting Complaints and Symptoms

The symptoms of metastatic disease depend on the location of the metastasis and the extent of tumour spread:

Common Symptoms by Site:

Liver metastasis:

Abdominal pain and **hepatomegaly**.

Jaundice due to bile duct obstruction.

Weight loss, **fatigue**, and **anorexia**.

Ascites due to portal hypertension.

Lung metastasis:

Cough, **dyspnoea**, and **haemoptysis** (coughing up blood).

Pleural effusion causing chest discomfort or difficulty breathing.

Bone metastasis:

Bone pain, commonly in the spine, ribs, and pelvis.

Pathological fractures from weakened bones.

Hypercalcaemia, presenting with confusion, constipation, and nausea.

Brain metastasis:

Headaches, seizures, and neurological deficits (e.g., weakness, sensory changes).

Cognitive impairment or personality changes.

Lymphatic metastasis:

Painless lymphadenopathy (enlarged lymph nodes).

Lymphoedema due to obstruction of lymphatic drainage.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

To detect **anaemia, thrombocytopenia, or leukocytosis**, which may suggest bone marrow involvement.

Liver function tests (LFTs):

Abnormal **ALT, AST, and bilirubin** levels may suggest **liver metastasis**.

Calcium levels:

Elevated in **bone metastasis** due to tumour-induced **hypercalcaemia**.

Tumour markers:

CEA (Carcinoembryonic antigen) for colorectal cancer.

CA 19-9 for pancreatic cancer.

CA 15-3 for breast cancer.

PSA (Prostate-specific antigen) for prostate cancer.

b) Imaging:

CT Scan:

CT chest, abdomen, and pelvis is the first-line imaging modality to assess for metastatic spread to the lungs, liver, and other abdominal organs.

MRI:

Best for detecting **brain metastasis** and assessing **spinal cord compression** from bone metastasis.

PET-CT Scan:

Combines metabolic and anatomical imaging to detect **occult metastasis** and assess the full extent of disease.

Bone Scan:

To detect **bone metastasis** in patients presenting with bone pain or elevated calcium levels.

c) Special Tests:

Biopsy of metastatic lesion:

In cases where the primary tumour is unknown, a biopsy of the metastatic lesion can confirm the diagnosis and help identify the primary site through histopathological examination and **immunohistochemical staining**.

4. Explanation of Investigations

CT Scan: Provides a detailed image of the chest, abdomen, and pelvis, helping detect secondary tumours in the lungs, liver, and other abdominal organs.

PET-CT: Detects metabolically active cells, useful for identifying metastases that may not be seen on a CT scan alone.

Bone Scan: Uses a radioactive tracer to identify areas of increased bone metabolism, characteristic of bone metastasis.

5. Diagnosis Criteria for Metastatic Disease

The diagnosis of metastatic disease is made based on:

Clinical symptoms: Such as bone pain, neurological signs, or unexplained weight loss.

Imaging findings: Confirming the presence of distant metastases on CT, MRI, or PET-CT scans.

Histological confirmation:

Biopsy of a metastatic lesion can confirm the presence of cancer cells and identify the primary tumour type if it is unknown.

6. First-Line Therapy According to Guidelines

a) General Principles of Management:

Systemic therapy:

Chemotherapy: Used for cancers like colorectal, breast, and lung cancer with known sensitivity to cytotoxic agents.

Targeted therapy: Based on molecular profiling of the tumour (e.g., **HER2-targeted therapy** for HER2-positive breast cancer, **EGFR inhibitors** for non-small cell lung cancer).

Immunotherapy: Checkpoint inhibitors (e.g., **pembrolizumab**) are used in some cancers (e.g., melanoma, lung cancer) to stimulate the immune system to attack the cancer.

Radiotherapy:

Palliative radiotherapy: Used to relieve symptoms such as bone pain or spinal cord compression.

Whole-brain radiotherapy: Used to manage brain metastasis and reduce neurological symptoms.

Surgical intervention:

Surgical resection: May be considered for **solitary liver** or **lung metastases**, particularly in colorectal cancer.

Orthopaedic surgery: To stabilise bones at risk of pathological fracture due to bone metastasis.

b) Site-Specific Therapies:

Liver metastasis:

Resection or **radiofrequency ablation (RFA)** for isolated liver metastases, especially from colorectal cancer.

Transarterial chemoembolisation (TACE) for palliative control of inoperable liver metastasis.

Bone metastasis:

Bisphosphonates (e.g., **zoledronic acid**) or **denosumab** to reduce bone resorption and decrease the risk of fractures.

Radiotherapy for local control and pain relief.

Brain metastasis:

Stereotactic radiosurgery (SRS) for localised brain metastases.

Corticosteroids to reduce cerebral oedema and alleviate neurological symptoms.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery is generally contraindicated in patients with **multiple metastatic sites** or **poor performance status**, as it may not improve survival.

Chemotherapy may be contraindicated in patients with **severe organ dysfunction** or **frailty**.

b) Second-Line Therapy:

Second-line chemotherapy (e.g., **irinotecan** for colorectal cancer or **docetaxel** for prostate cancer) may be considered in patients who progress on first-line therapy.

Immunotherapy and **targeted therapies** may be used in **advanced or refractory cases** based on tumour molecular profiling.

8. Routine Monitoring and Follow-Up

Regular imaging:

CT scans or **MRI** every 3-6 months to assess response to therapy and monitor for disease progression.

Blood tests:

Monitor **tumour markers** (e.g., CEA for colorectal cancer) and routine blood counts to assess for treatment-related complications (e.g., myelosuppression).

Symptom management:

Patients should be regularly evaluated for symptoms of pain, weight loss, or new neurological deficits that may indicate progression of metastatic disease.

9. Complications of Metastatic Disease

Pathological fractures: From bone metastasis, leading to disability and requiring surgical intervention.

Spinal cord compression: Can occur with vertebral metastasis, presenting as back pain, weakness, and sensory loss, requiring urgent treatment with corticosteroids and radiotherapy.

Hypercalcaemia: Common in bone metastasis, presenting with confusion, nausea, and constipation, requiring prompt treatment with intravenous fluids and bisphosphonates.

Hepatic failure: Due to extensive liver metastasis leading to jaundice, coagulopathy, and encephalopathy.

Seizures and neurological deficits: From brain metastasis, often requiring steroids and anticonvulsants.

Summary of Key Points for Metastatic Disease

Metastatic disease refers to the spread of cancer from the primary tumour to distant organs, commonly affecting the liver, lungs, bones, and brain.

Common symptoms include weight loss, abdominal pain, bone pain, neurological deficits, and jaundice, depending on the site of metastasis.

Diagnosis is based on **imaging (CT, MRI, PET-CT)**, tumour markers, and **biopsy**.

First-line therapies include **systemic chemotherapy, targeted therapy, immunotherapy, radiotherapy**, and **surgical intervention** for selected cases.

Monitoring involves regular imaging, blood tests, and symptom management to assess disease progression and response to therapy.

201. Appendicitis

1. Detailed Definition of Appendicitis

Appendicitis is the acute inflammation of the **vermiform appendix**, a small, tube-like structure attached to the cecum. It is one of the most common causes of acute abdominal pain and requires urgent surgical intervention to prevent complications such as **perforation** or **peritonitis**. The inflammation is typically due to obstruction of the appendiceal lumen by **faecaliths**, **lymphoid hyperplasia**, or **foreign bodies**.

2. Common Presenting Complaints and Symptoms

Patients with appendicitis typically present with a **progressive onset** of abdominal pain. The classical symptoms include:

Abdominal pain:

Initially vague and **periumbilical**, then localises to the **right iliac fossa (RIF)** as the inflammation progresses.

Nausea and vomiting:

Often follow the onset of abdominal pain.

Loss of appetite (anorexia):

Common early symptom in most cases.

Low-grade fever:

Mild elevation in body temperature, although high fever may indicate complications like perforation or abscess formation.

Rebound tenderness and **guarding** in the right lower quadrant (RIF).

Rovsing's sign:

Pain in the RIF when palpating the left lower quadrant.

McBurney's point tenderness:

Located one-third of the distance from the anterior superior iliac spine to the umbilicus, often tender in appendicitis.

Obturator sign and **psoas sign:**

These manoeuvres elicit pain and indicate possible retrocaecal appendicitis.

3. First-Line Investigations

a) Blood Tests:

Full blood count (FBC):

Leukocytosis with a **neutrophil predominance** is commonly seen in appendicitis, indicating infection or inflammation.

C-reactive protein (CRP):

Elevated in response to inflammation.

b) Imaging:

Ultrasound (USS):

Commonly used first-line, especially in children and pregnant women. It can identify an **enlarged, non-compressible appendix** and assess for complications such as abscess or perforation.

CT Scan:

CT abdomen and pelvis is the gold standard imaging modality in adults, with high sensitivity and specificity for diagnosing appendicitis.

It can detect appendiceal enlargement, wall thickening, periappendiceal fat stranding, and free fluid indicating perforation.

MRI:

Occasionally used in pregnant patients where radiation from CT should be avoided.

c) Special Tests:

Urinalysis:

Used to rule out **urinary tract infection** (UTI) or renal pathology, which can mimic appendicitis.

4. Explanation of Investigations

Full blood count (FBC): Elevated white blood cell count (leukocytosis) and neutrophilia are common in appendicitis, indicating bacterial infection and inflammation.

Ultrasound: Non-invasive and radiation-free, ultrasound can visualise an inflamed appendix and assess for abscess formation, particularly useful in children and pregnant women.

CT scan: Provides detailed images of the appendix and surrounding structures, making it the gold standard for appendicitis diagnosis in adults.

5. Diagnosis Criteria for Appendicitis

The diagnosis of appendicitis is **clinical**, supported by **imaging** and **blood tests**:

Clinical features: Progressive abdominal pain, nausea, vomiting, loss of appetite, and tenderness at McBurney's point.

Blood tests: Elevated white blood cell count and CRP.

Imaging: Ultrasound or CT findings of an inflamed appendix or associated complications such as abscess or perforation.

6. First-Line Therapy According to Guidelines

The first-line treatment for appendicitis is **surgical**:

a) Surgical Intervention:

Appendectomy:

Laparoscopic appendectomy is the preferred method due to reduced postoperative pain, shorter hospital stay, and faster recovery compared to open surgery.

Open appendectomy is still used in complicated cases or where laparoscopic equipment is unavailable.

b) Antibiotics:

Pre-operative antibiotics:

Intravenous antibiotics, such as **cefuroxime** and **metronidazole**, are typically administered before surgery to reduce the risk of postoperative infection.

Non-operative management:

In selected cases (e.g., patients with a **contained appendiceal abscess** or those who are not surgical candidates), **antibiotic therapy** may be used to manage uncomplicated appendicitis. However, this is less common.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery may be delayed or contraindicated in patients with significant comorbidities that increase surgical risk. In these cases, **non-operative management** with antibiotics may be considered.

b) Second-Line Therapy:

Antibiotic-only treatment:

In cases where surgery is contraindicated, or patients refuse surgery, antibiotics alone (e.g., **piperacillin-tazobactam**) may be used, although there is a higher risk of recurrence.

Drainage of abscess:

For patients presenting with a **perforated appendix** or an appendiceal **abscess**, surgical drainage or percutaneous drainage of the abscess may be required, followed by interval appendectomy.

8. Routine Monitoring and Follow-Up

Postoperative monitoring:

Patients should be monitored for signs of **infection**, **bleeding**, or **bowel injury** after appendectomy.

Monitor for **fever**, **tachycardia**, or increasing abdominal pain, which could suggest postoperative complications such as abscess formation or wound infection.

Follow-up:

A routine follow-up appointment after surgery is important to assess **wound healing** and ensure there are no complications.

9. Complications of Appendicitis

Perforation: Occurs in approximately 20% of cases if not treated promptly, leading to **peritonitis** and increased morbidity.

Abscess formation: Occurs when a perforated appendix is walled off by surrounding structures, leading to a localised abscess.

Peritonitis: Generalised infection of the abdominal cavity due to a ruptured appendix, leading to severe infection and septic shock if untreated.

Sepsis: In cases of delayed treatment or perforation, patients may develop **sepsis**, requiring urgent medical intervention.

Adhesions: Postoperative adhesions can occur, leading to future bowel obstruction.

Summary of Key Points for Appendicitis

Appendicitis is the acute inflammation of the appendix, usually caused by luminal obstruction, leading to right lower quadrant abdominal pain.

Common symptoms include nausea, vomiting, fever, and localised tenderness at **McBurney's point**.

Diagnosis is supported by **blood tests** (elevated WBC, CRP) and **imaging** (ultrasound or CT).

First-line treatment is **laparoscopic appendectomy**, with pre-operative antibiotics to reduce the risk of infection.

Complications include **perforation**, **abscess formation**, and **peritonitis** if untreated.

202. Cholecystitis

1. Detailed Definition of Cholecystitis

Cholecystitis is the inflammation of the **gallbladder**, usually resulting from **obstruction** of the cystic duct by a **gallstone** (calculous cholecystitis). This leads to gallbladder distention, bacterial infection, and inflammation. Less commonly, it can occur without gallstones (acalculous cholecystitis), particularly in critically ill patients. If untreated, cholecystitis can progress to **gallbladder perforation**, **empyema**, or **peritonitis**.

2. Common Presenting Complaints and Symptoms

The symptoms of acute cholecystitis typically develop after eating fatty meals and include:

Right upper quadrant (RUQ) abdominal pain:

Often **severe**, persistent, and may radiate to the **right shoulder** or **back**.

Fever:

Often present, indicating inflammation or infection of the gallbladder.

Nausea and vomiting:

Common in the acute phase of the illness.

Murphy's sign:

Pain on deep inspiration when the RUQ is palpated, indicative of gallbladder inflammation.

Jaundice:

Occurs less commonly but may be present if there is obstruction of the common bile duct.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Leukocytosis is usually present, indicating infection or inflammation.

Liver function tests (LFTs):

Mildly elevated **ALT**, **AST**, **ALP**, and **bilirubin** levels may indicate bile duct involvement.

C-reactive protein (CRP):

Elevated, reflecting the inflammatory process.

b) Imaging:

Ultrasound:

First-line imaging for suspected cholecystitis. Ultrasound can detect:

Gallstones.

Thickening of the gallbladder wall (>3mm).

Pericholecystic fluid (fluid around the gallbladder).

Sonographic Murphy's sign: Tenderness over the gallbladder during ultrasound probe palpation.

CT Scan:

May be used if ultrasound is inconclusive or if complications such as **gallbladder perforation** or **abscess** are suspected.

Magnetic Resonance Cholangiopancreatography (MRCP):

Used in cases where there is suspicion of **common bile duct stones** (choledocholithiasis), which may require further intervention.

c) Special Tests:

HIDA (Hepatobiliary Iminodiacetic Acid) Scan:

A nuclear medicine test used when the diagnosis is unclear. It assesses gallbladder function and can confirm **cystic duct obstruction**.

4. Explanation of Investigations

Ultrasound: Non-invasive and widely available, it is the first-choice imaging modality for visualising gallstones and signs of gallbladder inflammation.

HIDA scan: Used when the diagnosis is uncertain, particularly in cases where the ultrasound is normal but clinical suspicion remains high. It assesses bile flow and can confirm obstruction.

LFTs: Elevated liver enzymes and bilirubin may indicate involvement of the bile ducts, either due to stone obstruction or cholangitis.

5. Diagnosis Criteria for Cholecystitis

The diagnosis of acute cholecystitis is made based on:

Clinical features: RUQ pain, fever, nausea, and a positive Murphy's sign.

Blood tests: Leukocytosis and elevated inflammatory markers.

Imaging: Ultrasound findings of gallstones, gallbladder wall thickening, pericholecystic fluid, and a positive sonographic Murphy's sign.

6. First-Line Therapy According to Guidelines

a) Non-Surgical Management:

Supportive care:

Intravenous fluids: To maintain hydration and correct electrolyte imbalances.

Nil by mouth (NPO): To rest the gallbladder and reduce further irritation.

Analgesia:

NSAIDs (e.g., **ibuprofen** or **diclofenac**) for pain control.

Opioids (e.g., **morphine**) may be required in severe cases.

Antibiotics:

Antibiotics should be started if there is evidence of infection, especially in severe cases.

First-line antibiotics include **cefuroxime** or **piperacillin-tazobactam**, often combined with **metronidazole** to cover anaerobic organisms.

b) Surgical Management:

Laparoscopic Cholecystectomy:

Gold standard for treating acute calculous cholecystitis.

Surgery is usually performed **early (within 24-72 hours)** after diagnosis to prevent complications such as perforation or abscess formation.

Percutaneous Cholecystostomy:

May be performed as a temporising measure in patients who are **poor surgical candidates** (e.g., critically ill patients) to drain the gallbladder and relieve the obstruction.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery may be contraindicated in patients with significant comorbidities or poor surgical risk. In such cases, non-surgical management and **percutaneous cholecystostomy** may be required.

b) Second-Line Therapy:

Antibiotic therapy:

In patients who are not immediate surgical candidates, antibiotics can help control infection and inflammation.

Consider broadening antibiotic coverage if there is no improvement or if sepsis develops.

8. Routine Monitoring and Follow-Up

Postoperative monitoring:

Monitor for signs of **infection**, **bile leaks**, or other surgical complications.

Follow-up imaging:

If the gallbladder is not removed, repeat **ultrasound** or **HIDA scan** may be needed to assess for resolution of inflammation or to check for recurrence.

LFT monitoring:

Regular monitoring of liver function tests to ensure there is no ongoing obstruction or bile duct injury.

9. Complications of Cholecystitis

Gallbladder perforation: Untreated cholecystitis can lead to rupture of the gallbladder, resulting in peritonitis and sepsis.

Pericholecystic abscess: A walled-off collection of pus around the gallbladder may occur, often requiring drainage.

Biliary peritonitis: Perforation of the gallbladder or bile duct can lead to bile leakage into the abdominal cavity, causing peritonitis.

Empyema: Collection of pus within the gallbladder due to infection.

Cholangitis: Infection of the bile ducts, presenting with **Charcot's triad** (fever, jaundice, and RUQ pain) and requiring urgent treatment.

Chronic cholecystitis: Recurrent episodes of acute inflammation can lead to chronic scarring and dysfunction of the gallbladder, often requiring elective cholecystectomy.

Summary of Key Points for Cholecystitis

Cholecystitis is the inflammation of the gallbladder, most often caused by gallstones blocking the cystic duct.

Symptoms include RUQ pain, nausea, vomiting, fever, and a positive **Murphy's sign**.

Diagnosis is confirmed by **blood tests** showing elevated WBC and CRP, and **imaging** (ultrasound showing gallstones and an inflamed gallbladder).

First-line treatment is **laparoscopic cholecystectomy**, with antibiotics used to control infection.

Complications of untreated cholecystitis include **gallbladder perforation**, **peritonitis**, and **abscess formation**.

203. Acute Cholangitis

1. Detailed Definition of Acute Cholangitis

Acute cholangitis, also known as **ascending cholangitis**, is an infection of the **bile ducts**, typically caused by **biliary obstruction** (e.g., gallstones, strictures, or tumours) that allows bacteria from the gastrointestinal tract to ascend into the biliary system. It is a serious and potentially life-threatening condition requiring urgent medical intervention.

2. Common Presenting Complaints and Symptoms

The classic clinical presentation of acute cholangitis is known as **Charcot's triad**, which includes:

Fever with rigors: A hallmark of infection.

Right upper quadrant (RUQ) abdominal pain.

Jaundice: Occurs due to biliary obstruction leading to the accumulation of bilirubin.

Reynolds' pentad is an extension of Charcot's triad and includes two additional features, suggesting severe disease or sepsis:

Hypotension.

Confusion or altered mental status.

Other symptoms include:

Nausea and vomiting.

Fatigue.

Pruritus: Due to bile salt deposition in the skin.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Leukocytosis with neutrophilia, indicating infection.

Liver function tests (LFTs):

Elevated **bilirubin**, **alkaline phosphatase (ALP)**, and **gamma-glutamyl transferase (GGT)**, consistent with cholestasis.

Elevated **AST** and **ALT** may indicate associated liver inflammation.

C-reactive protein (CRP):

Elevated, reflecting the inflammatory response.

Blood cultures:

Should be taken to identify the causative organism and guide antibiotic therapy.

b) Imaging:

Ultrasound:

First-line imaging to assess for **biliary obstruction**. Ultrasound can identify **bile duct dilatation**, **gallstones**, and signs of infection such as **thickening of the bile duct walls**.

Magnetic Resonance Cholangiopancreatography (MRCP):

Non-invasive and provides excellent imaging of the bile ducts to detect stones, strictures, or tumours causing obstruction.

Endoscopic Retrograde Cholangiopancreatography (ERCP):

Used for both **diagnosis** and **treatment** of biliary obstruction. ERCP can visualise the bile ducts, remove stones, and place stents if needed.

CT Scan:

Sometimes used to identify complications like **abscesses, perforation, or pancreatitis**.

4. Explanation of Investigations

Liver function tests: Elevated bilirubin and ALP are indicative of biliary obstruction. AST and ALT may be elevated if liver damage is present.

Ultrasound: Provides a non-invasive way to assess the gallbladder, bile ducts, and liver. It can detect biliary obstruction and complications such as gallstones or bile duct dilation.

MRCP: Provides detailed images of the bile ducts and is used if ultrasound is inconclusive or if more precise imaging is needed without invasive procedures.

ERCP: Allows direct visualisation of the bile ducts and also facilitates therapeutic intervention, such as stone removal or stent placement to relieve obstruction.

5. Diagnosis Criteria for Acute Cholangitis

The diagnosis of acute cholangitis is based on **clinical features, blood tests, and imaging findings**, following the **Tokyo Guidelines (TG18)**:

Tokyo Guidelines (TG18) Criteria:

Systemic inflammation:

Fever and/or **shaking chills**.

Elevated **white blood cell count** or other markers of inflammation (e.g., CRP).

Cholestasis:

Jaundice, or abnormal liver function tests (ALP, GGT, AST, ALT, bilirubin).

Imaging:

Biliary dilatation or evidence of the underlying aetiology (e.g., stones, strictures, or tumours).

Definitive diagnosis requires the presence of **systemic inflammation, cholestasis, and biliary imaging** confirming obstruction.

6. First-Line Therapy According to Guidelines

a) Initial Medical Management:

Supportive care:

Intravenous fluids: To manage dehydration and hypotension.

Electrolyte correction as needed.

Antibiotics:

Broad-spectrum intravenous antibiotics should be initiated early to control infection, with coverage for **gram-negative bacteria** (e.g., **Escherichia coli**, **Klebsiella**) and **anaerobes**.

Common regimens include:

Ceftriaxone or **piperacillin-tazobactam**, often combined with **metronidazole** to cover anaerobes.

Antibiotic therapy should be adjusted based on **blood culture** results.

b) Interventional Treatment:

Endoscopic Retrograde Cholangiopancreatography (ERCP):

ERCP is the **definitive treatment** for relieving biliary obstruction.

During ERCP, stones can be removed, and **stents** can be placed to relieve obstruction.

In patients with cholangitis and persistent biliary obstruction, ERCP is performed urgently to prevent sepsis.

Percutaneous transhepatic biliary drainage (PTBD):

If ERCP is not possible or unsuccessful, PTBD can be performed to drain bile and relieve obstruction.

Surgical intervention:

Cholecystectomy may be necessary if gallstones are the underlying cause.

Surgery is usually reserved for cases where ERCP and other non-invasive measures fail, or in cases of **complications** (e.g., gallbladder perforation).

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

ERCP may be contraindicated in patients with **severe comorbidities** or those who are at high risk of complications from endoscopic procedures. In such cases, **PTBD** or **surgical intervention** may be preferred.

b) Second-Line Therapy:

PTBD is used in cases where ERCP is unsuccessful or contraindicated.

Percutaneous cholecystostomy may be performed in patients with **gallbladder empyema** or severe infection that cannot be resolved with antibiotics alone.

8. Routine Monitoring and Follow-Up

Monitoring after ERCP:

Monitor for complications such as **bleeding**, **pancreatitis**, or **bile duct perforation** following the procedure.

Liver function tests:

Monitor **LFTs** to assess resolution of the biliary obstruction and response to treatment.

Blood cultures:

Monitor blood culture results to adjust antibiotic therapy accordingly and ensure the infection is adequately treated.

Repeat imaging:

May be required to ensure the biliary system is clear of stones or to assess for any residual obstruction.

9. Complications of Acute Cholangitis

Sepsis: If left untreated, cholangitis can rapidly progress to sepsis, septic shock, and multiorgan failure.

Liver abscess: Untreated biliary obstruction and infection can lead to the formation of liver abscesses.

Biliary stricture: Chronic inflammation from recurrent cholangitis can lead to bile duct strictures, requiring long-term monitoring and possible stenting.

Acute pancreatitis: ERCP and gallstones can both precipitate acute pancreatitis.

Chronic cholangitis: Recurrent bouts of cholangitis can lead to chronic inflammation and scarring of the bile ducts.

Summary of Key Points for Acute Cholangitis

Acute cholangitis is an infection of the bile ducts usually due to biliary obstruction, most commonly from gallstones.

Charcot's triad (fever, RUQ pain, jaundice) and **Reynolds' pentad** (shock, confusion) are key clinical signs.

Diagnosis is confirmed by **blood tests**, **imaging** (ultrasound or MRCP), and clinical features.

First-line treatment involves **IV antibiotics**, **fluid resuscitation**, and **ERCP** to relieve biliary obstruction.

Complications include **sepsis**, **liver abscess**, and **chronic bile duct strictures** if not treated promptly.

204. Gastrointestinal Perforation

1. Detailed Definition of Gastrointestinal Perforation

Gastrointestinal (GI) perforation refers to a **hole** or **rupture** in the wall of any part of the **gastrointestinal tract**, allowing the contents of the stomach, intestines, or colon to spill into the **peritoneal cavity**. This leads to **peritonitis**, a life-threatening condition that requires

emergency medical and often surgical intervention. Perforation can occur in the **stomach, duodenum, small intestine, colon, or rectum**, due to various causes such as **peptic ulcer disease, trauma, diverticulitis, or malignancy**.

2. Common Presenting Complaints and Symptoms

GI perforation often presents acutely and requires urgent assessment. The classic presentation includes:

Severe, sudden onset of abdominal pain:

Often described as **sharp** and **generalised**. It may start locally and then become diffuse.

Pain may radiate to the **shoulders** (referred pain due to diaphragmatic irritation).

Abdominal rigidity and guarding:

The abdomen is often **rigid** due to involuntary contraction of abdominal muscles (the **board-like abdomen**).

Signs of peritonitis:

Rebound tenderness: Pain worsens when pressure is released after palpation.

Absent bowel sounds: Indicative of paralytic ileus.

Systemic signs:

Fever, tachycardia, and hypotension.

Nausea and vomiting.

Tachypnoea due to diaphragmatic irritation from peritoneal fluid or air.

Shock (in advanced cases):

Hypotension, altered mental status, and signs of sepsis if left untreated.

3. First-Line Investigations

a) Blood Tests:

Full blood count (FBC):

Leukocytosis with neutrophilia indicates infection or peritoneal inflammation.

C-reactive protein (CRP):

Typically elevated due to inflammation.

Urea and electrolytes (U&Es):

To assess dehydration, electrolyte disturbances, and possible renal impairment.

Arterial blood gas (ABG):

May show **metabolic acidosis** due to sepsis and lactic acidosis.

Blood cultures:

Important for identifying the pathogen if sepsis is suspected.

b) Imaging:

Erect Chest X-ray:

First-line imaging to detect **free air under the diaphragm** (pneumoperitoneum), a classic sign of perforation.

Abdominal X-ray:

May also show free air in the peritoneal cavity or other signs such as air-fluid levels suggestive of obstruction.

CT Abdomen/Pelvis:

Gold standard for diagnosing GI perforation.

It can accurately localise the perforation, detect the cause (e.g., peptic ulcer, tumour, diverticulitis), and assess for complications like abscesses or free fluid.

c) Special Tests:

Ultrasound:

May be used in some cases to detect free fluid or abscesses, but it is less sensitive than CT for detecting perforation.

4. Explanation of Investigations

Erect Chest X-ray: The most rapid and easily accessible investigation to identify free air under the diaphragm, indicating perforation.

CT Abdomen/Pelvis: Provides detailed images to locate the site of perforation, assess the severity, and guide further management. It is crucial in determining the cause of perforation.

Blood tests: Elevated white cell count and CRP indicate infection or inflammation. ABG helps monitor metabolic disturbances and the severity of the patient's condition.

5. Diagnosis Criteria for GI Perforation

GI perforation is diagnosed based on:

Clinical signs: Acute abdominal pain, tenderness, guarding, and systemic signs of sepsis.

Blood tests: Leukocytosis, elevated CRP, and metabolic acidosis (in advanced cases).

Imaging: Presence of **free air** under the diaphragm on an erect chest X-ray or confirmed on a **CT scan**.

6. First-Line Therapy According to Guidelines

a) Initial Medical Management:

Resuscitation:

IV fluids: Immediate fluid resuscitation to correct dehydration and prevent shock. **Crystalloids** are usually used.

Broad-spectrum antibiotics:

Empiric antibiotics should be started as soon as perforation is suspected to cover **gram-negative bacteria** and **anaerobes**.

Common choices include **piperacillin-tazobactam** or **ceftriaxone** plus **metronidazole**.

Nil by mouth (NPO):

The patient should not eat or drink to avoid exacerbating the perforation and prevent further leakage of gastrointestinal contents into the peritoneum.

b) Surgical Intervention:

Emergency laparotomy or laparoscopy:

Surgery is the definitive treatment to repair the perforation and control contamination of the peritoneal cavity.

Depending on the cause and location, the surgeon may:

Perform **primary repair** of the perforation.

Resect part of the bowel if necessary (e.g., in cases of necrosis or malignancy).

Perform a **Hartmann's procedure** (resection with colostomy) for some cases of perforated diverticulitis or malignancy.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery may be delayed or contraindicated in patients who are too unstable for surgery (e.g., those in **septic shock**) until adequate resuscitation has been performed.

b) Second-Line Therapy:

Percutaneous drainage:

In cases of a contained abscess, **percutaneous drainage** under radiological guidance may be used if immediate surgery is not possible.

Conservative management:

In rare cases, small perforations may be managed conservatively with antibiotics and bowel rest, especially in patients who are poor surgical candidates.

8. Routine Monitoring and Follow-Up

Postoperative monitoring:

Regularly monitor for signs of **infection**, **bleeding**, and **anastomotic leaks** following surgical repair.

Monitor vital signs closely for signs of ongoing sepsis or shock.

Imaging:

Postoperative imaging may be necessary to assess for resolution of perforation or new complications like abscess formation.

Blood tests:

Repeat **FBC**, **CRP**, and **renal function** tests to monitor the patient's recovery and detect any complications such as sepsis or renal failure.

9. Complications of GI Perforation

Peritonitis: This is the most common and life-threatening complication, characterised by generalised infection of the peritoneal cavity.

Sepsis: Bacterial infection spreading from the peritoneal cavity can lead to sepsis and septic shock, requiring urgent intervention.

Abscess formation: Localised collection of pus may form if the perforation is contained, requiring drainage.

Fistula formation: A connection between the bowel and other organs may occur following perforation and surgery.

Adhesions: Post-surgical adhesions can form, leading to small bowel obstruction in the future.

Summary of Key Points for GI Perforation

GI perforation refers to the rupture of any part of the gastrointestinal tract, leading to the leakage of contents into the peritoneal cavity, causing peritonitis.

Common symptoms include sudden, severe abdominal pain, rigidity, fever, and signs of sepsis.

Diagnosis is confirmed with **clinical signs**, **blood tests**, and imaging, particularly **chest X-ray** and **CT scan**.

First-line treatment includes immediate **IV fluids**, **antibiotics**, and **surgical intervention** (laparotomy or laparoscopy) to repair the perforation.

Complications include **sepsis**, **abscess formation**, **fistulae**, and **adhesions**.

205. Peritonitis

1. Detailed Definition of Peritonitis

Peritonitis is an acute or chronic inflammation of the **peritoneum**, the thin layer of tissue that lines the inner wall of the abdomen and covers the abdominal organs. It is typically caused by a **bacterial infection**, though chemical irritation can also lead to peritonitis. The condition can be classified as either **primary** (spontaneous bacterial peritonitis, usually in patients with ascites) or **secondary** (due to perforation of abdominal organs such as the stomach, intestines, or appendix).

2. Common Presenting Complaints and Symptoms

Patients with peritonitis present with **acute and severe abdominal pain**. Key symptoms include:

Severe, generalised abdominal pain:

Often described as sharp, constant, and worsening. Initially, it may be localised but quickly spreads.

Rebound tenderness: The pain intensifies when pressure is released after palpation.

Abdominal guarding and rigidity:

The abdomen is firm and tender due to involuntary contraction of the abdominal muscles.

Fever:

Suggests infection, particularly in bacterial peritonitis.

Nausea and vomiting:

Common symptoms associated with acute peritoneal inflammation.

Tachycardia and hypotension:

Signs of sepsis or shock due to systemic infection.

Absent bowel sounds:

Indicating paralytic ileus as the peritoneum is irritated.

Decreased urine output:

Due to dehydration or shock in severe cases.

3. First-Line Investigations

a) Blood Tests:

Full blood count (FBC):

Leukocytosis with neutrophilia, indicating infection or inflammation.

C-reactive protein (CRP):

Elevated, reflecting acute inflammation.

Urea and electrolytes (U&Es):

To assess dehydration, renal function, and electrolyte imbalances.

Arterial blood gas (ABG):

May show **metabolic acidosis**, especially if the patient is septic.

Blood cultures:

Should be taken to identify the causative organism in cases of **septic peritonitis**.

b) Imaging:

Erect Chest X-ray:

Performed to look for **free air under the diaphragm** (pneumoperitoneum), which would suggest gastrointestinal perforation as the cause of secondary peritonitis.

Abdominal X-ray:

May reveal free air, air-fluid levels, or other signs indicating bowel obstruction or perforation.

CT Abdomen/Pelvis:

Gold standard for diagnosing peritonitis and identifying the cause (e.g., appendicitis, perforated peptic ulcer, diverticulitis). It can show free fluid, abscesses, or bowel perforation.

c) Paracentesis:

In cases of **spontaneous bacterial peritonitis (SBP)**, diagnostic **paracentesis** (aspiration of ascitic fluid) is essential:

Ascitic fluid analysis includes **cell count** (> 250 neutrophils/mm³ is diagnostic of SBP), **protein levels**, and **culture** to identify the organism causing the infection.

4. Explanation of Investigations

FBC and CRP: These blood tests indicate infection and inflammation, which are characteristic of peritonitis.

Erect chest X-ray: Free air under the diaphragm is a classic sign of gastrointestinal perforation, a common cause of secondary peritonitis.

CT scan: The most accurate imaging modality to confirm the diagnosis and identify the source of infection or inflammation.

Paracentesis: Critical for diagnosing spontaneous bacterial peritonitis, particularly in patients with ascites (e.g., due to cirrhosis).

5. Diagnosis Criteria for Peritonitis

The diagnosis of peritonitis is made based on:

Clinical features: Severe abdominal pain, guarding, fever, and signs of peritoneal irritation (rebound tenderness).

Blood tests: Leukocytosis and elevated CRP.

Imaging: Evidence of free air or free fluid on imaging, indicating perforation or inflammation.

Paracentesis findings (in cases of SBP): Elevated neutrophil count (>250 neutrophils/mm³) and positive bacterial cultures.

6. First-Line Therapy According to Guidelines

a) Initial Medical Management:

Supportive care:

Intravenous fluids: To correct dehydration, maintain blood pressure, and prevent shock.

Broad-spectrum antibiotics:

Empiric antibiotic therapy should be started as soon as peritonitis is suspected.

Common regimens include **piperacillin-tazobactam** or **ceftriaxone** combined with **metronidazole** to cover anaerobic organisms.

Antibiotic therapy should be adjusted based on culture results.

Pain management:

IV analgesia, such as opioids, to manage severe pain.

Nil by mouth (NPO):

Patients should be kept NPO to avoid exacerbating peritoneal irritation and prepare for possible surgery.

b) Surgical Management:

Emergency surgery:

Laparotomy or **laparoscopy** to identify and treat the underlying cause of secondary peritonitis, such as a perforated viscus (stomach, bowel) or ruptured appendix.

Surgical procedures may involve:

Primary repair of the perforation.

Resection of the affected portion of the bowel.

Drainage of any abscess or infected fluid collections.

Peritoneal lavage:

During surgery, the peritoneal cavity may be irrigated to remove infected material and prevent further contamination.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Immediate surgery may be contraindicated in critically ill patients who are hemodynamically unstable. In such cases, aggressive resuscitation is performed first, with surgery delayed until the patient is more stable.

b) Second-Line Therapy:

Percutaneous drainage:

For cases where an abscess or collection of fluid is present and the patient is not a surgical candidate, **percutaneous drainage** under radiological guidance may be performed.

Non-surgical management:

In cases of **spontaneous bacterial peritonitis**, antibiotics and supportive care are often sufficient, and surgery is typically not required.

8. Routine Monitoring and Follow-Up

Monitoring for sepsis:

Regular monitoring of **vital signs**, including temperature, heart rate, and blood pressure, to assess for signs of **sepsis** or **septic shock**.

Imaging:

Follow-up imaging may be required to assess for the resolution of the peritoneal infection or complications such as abscess formation.

Blood tests:

Repeat **FBC** and **CRP** to monitor response to treatment and detect ongoing inflammation or infection.

Paracentesis (in SBP):

In patients with ascites, serial paracentesis may be performed to ensure that the infection is resolving.

9. Complications of Peritonitis

Sepsis: Peritonitis can rapidly lead to sepsis, septic shock, and multiorgan failure if untreated.

Abscess formation: Localised collections of pus may form within the abdominal cavity, requiring drainage.

Ileus: Paralysis of the intestines can occur due to irritation of the peritoneum, resulting in **bowel obstruction**.

Adhesions: Post-infective or post-surgical adhesions can develop, leading to future bowel obstructions.

Death: If not treated promptly, peritonitis can lead to death, particularly in patients with sepsis or multiple organ failure.

Summary of Key Points for Peritonitis

Peritonitis is inflammation of the peritoneal lining, usually due to bacterial infection from gastrointestinal perforation or spontaneous bacterial peritonitis (SBP) in patients with ascites.

Common symptoms include severe generalised abdominal pain, fever, abdominal rigidity, and signs of sepsis.

Diagnosis is confirmed with **clinical examination**, **blood tests**, and **imaging** (chest X-ray or CT scan), and in cases of SBP, **paracentesis** is diagnostic.

First-line treatment includes **IV fluids**, **broad-spectrum antibiotics**, and **surgical intervention** for secondary peritonitis.

Complications include **sepsis**, **abscess formation**, **ileus**, and **adhesions**.

206. Intestinal Ischaemia

1. Detailed Definition of Intestinal Ischaemia

Intestinal ischaemia refers to a reduction in blood flow to the small or large intestines, resulting in tissue damage and, in severe cases, bowel necrosis. It can be classified into three main types:

Acute mesenteric ischaemia: A sudden loss of blood flow to the small intestine, typically due to an embolus or thrombosis of the **superior mesenteric artery (SMA)**.

Chronic mesenteric ischaemia: Often referred to as "intestinal angina," caused by atherosclerosis of the mesenteric arteries, leading to episodic postprandial pain.

Ischaemic colitis: A more common and less severe form of intestinal ischaemia, primarily affecting the colon and often caused by low-flow states.

2. Common Presenting Complaints and Symptoms

The clinical presentation of intestinal ischaemia varies depending on the type and severity.

Acute Mesenteric Ischaemia:

Severe abdominal pain:

Out of proportion to physical findings (pain is intense, but the abdomen may not be tender on palpation early on).

Nausea, vomiting, and diarrhoea: Common symptoms in early stages.

Hematochezia (bloody stools): May occur if bowel necrosis has developed.

Signs of sepsis: Hypotension, tachycardia, and fever, especially in advanced cases with bowel infarction.

Chronic Mesenteric Ischaemia:

Postprandial abdominal pain:

Occurs 15-30 minutes after eating, lasting for a few hours.

Weight loss:

Due to fear of eating (food aversion) and malnutrition.

Diarrhoea: May also be present due to poor intestinal perfusion.

Ischaemic Colitis:

Lower abdominal pain:

Typically cramping and located in the left lower quadrant.

Bloody diarrhoea:

The most common symptom, often occurring with pain.

Signs of systemic illness:

Fever, tachycardia, and hypotension may occur if there is extensive colonic ischaemia.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Leukocytosis may indicate inflammation, infection, or bowel necrosis.

Serum lactate:

Elevated levels indicate tissue hypoxia and are a marker of ischaemia, particularly in acute cases.

Urea and electrolytes (U&Es):

To assess dehydration, electrolyte imbalances, and renal function.

Arterial blood gas (ABG):

May show **metabolic acidosis** due to lactic acidosis from bowel ischaemia.

b) Imaging:

CT Angiography (CTA):

First-line imaging to diagnose acute mesenteric ischaemia. It provides detailed images of the mesenteric vasculature and can reveal occlusion of the SMA or other vessels, bowel wall thickening, or pneumatosis (gas in the bowel wall).

Doppler Ultrasound:

May be useful for evaluating **chronic mesenteric ischaemia** but is less commonly used in acute settings.

Plain Abdominal X-ray:

Often shows **non-specific findings** but may reveal pneumatosis or free air in the abdomen if bowel perforation has occurred.

Colonoscopy or flexible sigmoidoscopy:

Can be used to diagnose **ischaemic colitis**, revealing areas of colonic ulceration, oedema, or necrosis.

4. Explanation of Investigations

CT Angiography: The gold standard for diagnosing acute mesenteric ischaemia, as it can clearly identify vascular occlusion, bowel wall thickening, or pneumatosis.

Serum lactate: Elevated in tissue hypoxia, indicating bowel ischaemia or infarction.

Colonoscopy: In ischaemic colitis, it can reveal mucosal changes such as ulceration or necrosis, helping to confirm the diagnosis.

5. Diagnosis Criteria for Intestinal Ischaemia

The diagnosis of intestinal ischaemia is made based on:

Clinical presentation: Sudden onset of severe abdominal pain in acute mesenteric ischaemia, postprandial pain in chronic mesenteric ischaemia, and bloody diarrhoea with cramping pain in ischaemic colitis.

Blood tests: Elevated white blood cell count, high lactate, and metabolic acidosis on ABG.

Imaging: CTA showing vascular occlusion or bowel changes, or colonoscopy showing ischaemic changes in the colon.

6. First-Line Therapy According to Guidelines

a) Acute Mesenteric Ischaemia:

Resuscitation and supportive care:

Intravenous fluids: To correct dehydration, maintain blood pressure, and prevent shock.

Pain management: IV opioids are commonly used for severe pain.

Broad-spectrum antibiotics:

To cover for possible bowel necrosis and sepsis.

Common regimens include **piperacillin-tazobactam** or **ceftriaxone** plus **metronidazole**.

Surgical intervention:

Emergency laparotomy or **endovascular revascularisation** is the definitive treatment.

During surgery, the surgeon may:

Restore blood flow using thrombectomy or embolectomy.

Resect necrotic bowel if infarction has occurred.

Stenting may be done if the cause is chronic atherosclerotic narrowing.

b) Chronic Mesenteric Ischaemia:**Lifestyle modification:**

Dietary changes: Patients are advised to eat smaller, more frequent meals to reduce postprandial blood demand.

Endovascular treatment:

Balloon angioplasty or **stenting** may be performed to restore blood flow in patients with significant arterial narrowing.

Surgical revascularisation:

May be required in patients who are not candidates for endovascular therapy or if symptoms persist despite treatment.

c) Ischaemic Colitis:

Conservative management (in most cases):

Bowel rest, intravenous fluids, and broad-spectrum antibiotics.

Surgery:

Required in cases of bowel necrosis, perforation, or persistent symptoms despite medical treatment.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:**

In cases of **severe co-morbidities**, surgery may be delayed until the patient is stabilised with aggressive resuscitation.

b) Second-Line Therapy:**Endovascular therapy:**

In patients who are poor candidates for open surgery, **endovascular revascularisation** (angioplasty and stenting) may be an alternative.

Non-surgical management:

In less severe cases of ischaemic colitis, conservative management with **fluids, antibiotics,** and **bowel rest** may be sufficient.

8. Routine Monitoring and Follow-Up

Postoperative monitoring:

Regular monitoring of **vital signs** and **abdominal examination** to detect signs of infection, bleeding, or bowel perforation following surgery.

Lactate and blood gas monitoring:

Regular measurement of **serum lactate** and **ABG** to assess resolution of the ischaemia.

Repeat imaging:

Follow-up **CTA** or **ultrasound** may be required to assess for ongoing vascular compromise.

Nutritional support:

In cases of chronic mesenteric ischaemia, patients may need dietary guidance and nutritional supplements due to food aversion and weight loss.

9. Complications of Intestinal Ischaemia

Bowel necrosis: If blood flow is not restored in time, parts of the bowel may die, requiring resection.

Sepsis: Bacterial translocation from the ischaemic bowel can lead to sepsis, septic shock, and multi-organ failure.

Perforation: Necrosis of the bowel wall can lead to perforation, which is a surgical emergency.

Short bowel syndrome: In patients requiring extensive bowel resection, malabsorption and nutritional deficiencies can occur.

Strictures: Chronic ischaemia may lead to scarring and narrowing of the intestines, causing bowel obstruction.

Summary of Key Points for Intestinal Ischaemia

Intestinal ischaemia results from reduced blood flow to the intestines, causing tissue damage. It can be acute or chronic, and may affect the small intestine (mesenteric ischaemia) or colon (ischaemic colitis).

Symptoms include severe abdominal pain (out of proportion to physical findings in acute mesenteric ischaemia), postprandial pain and weight loss (in chronic mesenteric ischaemia),

207. Intestinal Obstruction and Ileus

1. Detailed Definition of Intestinal Obstruction and Ileus

Intestinal obstruction refers to a mechanical blockage or functional impairment that prevents the normal passage of intestinal contents through the bowel. It can occur in either the **small intestine** or the **large intestine**. The causes can be **mechanical**, such as **adhesions**, **hernias**, **tumours**, or **volvulus**, or **functional**, where there is a lack of peristalsis (e.g., **paralytic ileus**).

Ileus refers to a **temporary impairment of bowel motility** in the absence of mechanical obstruction, commonly following surgery, peritonitis, or severe illness.

2. Common Presenting Complaints and Symptoms

Intestinal Obstruction:

Abdominal pain:

Colicky in nature, typically intermittent. Pain is more localised in mechanical obstruction (e.g., due to hernias or tumours).

Distension:

More pronounced in **large bowel obstruction** and associated with tympanic sounds on percussion.

Vomiting:

Can be bilious in **small bowel obstruction** or faeculent in **large bowel obstruction**.

Failure to pass gas or stool (obstipation):

Indicates complete obstruction, particularly in the large intestine.

Visible peristalsis:

In thin patients, exaggerated peristaltic movements may be seen as the bowel attempts to overcome the obstruction.

Ileus:

Generalised abdominal discomfort:

Typically less severe than mechanical obstruction and more diffuse.

Abdominal distension:

More uniform and pronounced.

Nausea and vomiting.

Absent bowel sounds:

A key distinguishing feature of ileus as there is no peristalsis.

No passage of stool or gas (similar to obstruction but due to functional paralysis).

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Leukocytosis may indicate an underlying infection, inflammation, or ischaemia (e.g., strangulated hernia or volvulus).

Urea and electrolytes (U&Es):

Electrolyte disturbances (hypokalaemia, hyponatraemia) are common, particularly in patients with vomiting or diarrhoea.

C-reactive protein (CRP):

Elevated in cases of inflammation, infection, or ischaemia.

Lactate:

Elevated lactate may suggest **bowel ischaemia**, particularly in volvulus or strangulated hernia.

b) Imaging:

Abdominal X-ray:

The first-line imaging modality for suspected obstruction.

Small bowel obstruction: Dilated loops of small bowel with **air-fluid levels** and **central** location of dilated loops.

Large bowel obstruction: Dilated large bowel with **peripheral** distribution.

Ileus: Generalised distension of both the small and large bowel without air-fluid levels.

CT Abdomen/Pelvis:

Gold standard for identifying the cause of obstruction (e.g., adhesions, tumours, hernias, volvulus).

Can also help distinguish between **mechanical obstruction** and **functional ileus**.

Ultrasound:

Can be useful in diagnosing causes such as **intussusception** in children or identifying hernias.

Contrast studies (e.g., CT or barium enema):

May be used in cases of **large bowel obstruction** to assess for underlying malignancy or strictures.

4. Explanation of Investigations

Abdominal X-ray: Can rapidly identify dilated loops of bowel and air-fluid levels, characteristic of mechanical obstruction.

CT scan: Provides a more detailed evaluation of the cause, location, and severity of the obstruction and is critical in surgical planning.

Lactate: A marker of tissue hypoxia, which may indicate bowel ischaemia in cases of prolonged or complicated obstruction.

5. Diagnosis Criteria for Intestinal Obstruction and Ileus

The diagnosis is based on:

Clinical presentation: Symptoms of colicky pain, distension, vomiting, and failure to pass gas or stool.

Imaging: Abdominal X-ray or CT scan showing dilated loops of bowel, air-fluid levels, or other findings suggestive of mechanical obstruction or ileus.

Blood tests: Abnormalities such as leukocytosis, elevated lactate, or electrolyte imbalances suggest underlying complications or prolonged obstruction.

6. First-Line Therapy According to Guidelines

a) Non-operative Management:

Fluid resuscitation:

IV fluids are critical to correct dehydration and electrolyte imbalances due to vomiting and poor oral intake.

Nasogastric (NG) tube decompression:

Inserted to relieve abdominal distension, reduce vomiting, and decompress the bowel, especially in patients with **vomiting** or significant **distension**.

Electrolyte correction:

Replace any electrolyte disturbances, such as potassium or sodium.

Nil by mouth (NPO):

To rest the bowel and prevent further accumulation of contents.

b) Surgical Management:

Indications for surgery:

Strangulated hernia.

Volvulus or intussusception.

Bowel ischaemia or necrosis.

Complete bowel obstruction or failure to respond to conservative management within 48 hours.

Types of surgery:

Laparotomy or **laparoscopy** to remove the cause of obstruction (e.g., adhesions, hernia repair, tumour resection).

Resection of necrotic bowel if bowel infarction has occurred.

c) Ileus Management:

Conservative management:

Bowel rest, **IV fluids**, and **electrolyte correction** are usually sufficient.

Early mobilisation and stopping medications that reduce gut motility (e.g., opioids) can hasten recovery.

NG tube decompression:

Sometimes needed to relieve symptoms of distension and vomiting.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Immediate surgery may be contraindicated in patients with severe comorbidities or haemodynamic instability. Resuscitation and stabilisation with fluids, electrolyte correction, and NG decompression are prioritised.

b) Second-Line Therapy:

Endoscopic decompression:

May be used in cases of **sigmoid volvulus** to relieve the obstruction and reduce the volvulus without surgery.

Non-surgical management of ileus:

In some cases of **postoperative ileus**, prokinetic agents such as **metoclopramide** may be tried.

8. Routine Monitoring and Follow-Up

Clinical monitoring:

Frequent reassessment of abdominal pain, bowel sounds, and passage of stool or gas.

Imaging:

Repeat **abdominal X-rays** or **CT scans** may be required if the patient does not respond to conservative treatment.

Electrolyte monitoring:

Daily blood tests to monitor for electrolyte disturbances, particularly if the patient is on **IV fluids**.

Post-surgical follow-up:

Regular monitoring of surgical wounds and bowel function after operative management to detect any complications such as **infection** or **adhesions**.

9. Complications of Intestinal Obstruction and Ileus

Bowel ischaemia: Prolonged obstruction can lead to ischaemia and necrosis, requiring bowel resection.

Perforation: Increased intraluminal pressure may result in bowel perforation, leading to **peritonitis**.

Sepsis: If bowel necrosis or perforation occurs, bacterial translocation can lead to sepsis.

Short bowel syndrome: Extensive bowel resection may result in malabsorption and nutritional deficiencies.

Adhesions: Post-surgical adhesions can cause recurrent episodes of obstruction.

Summary of Key Points for Intestinal Obstruction and Ileus

Intestinal obstruction can be mechanical (e.g., adhesions, hernias, tumours) or functional (e.g., ileus) and presents with **abdominal pain, distension, and failure to pass stool or gas**.

Ileus is characterised by **absent peristalsis** and usually occurs after surgery or in severe illness.

Diagnosis is confirmed with **clinical features, abdominal X-ray, and CT scan**.

Initial management involves **IV fluids, NG decompression, and electrolyte correction**. Surgery is required in cases of **strangulation, volvulus, or necrosis**.

Complications include **bowel ischaemia, perforation, and sepsis** if not treated promptly.

208. Volvulus

1. Detailed Definition of Volvulus

Volvulus refers to the twisting of a part of the intestine around its mesenteric axis, which leads to an obstruction and can compromise the blood supply to that segment of the bowel. If left untreated, this can lead to **ischaemia, necrosis, and perforation** of the bowel.

The most common sites for volvulus include:

Sigmoid colon: Sigmoid volvulus is the most common type in adults, particularly in older people.

Caecum: Caecal volvulus occurs when the caecum twists on its axis, leading to obstruction.

Midgut volvulus: Seen more commonly in children, particularly infants with **malrotation** of the gut.

2. Common Presenting Complaints and Symptoms

Acute abdominal pain:

Sudden onset of **colicky** pain is typical in volvulus. The pain is often severe and may be more localised to the lower abdomen in cases of sigmoid volvulus.

Abdominal distension:

Distension is more pronounced in sigmoid volvulus due to gas and fluid accumulation.

Nausea and vomiting:

Vomiting may initially be bilious but can become faeculent in cases of prolonged obstruction.

Obstipation:

Patients typically report the inability to pass gas or stool, indicating bowel obstruction.

Tachycardia and hypotension:

Signs of shock may develop in advanced cases, especially if bowel ischaemia or perforation occurs.

3. First-Line Investigations**a) Blood Tests:****Full Blood Count (FBC):**

May show **leukocytosis**, indicating infection or bowel ischaemia.

Serum lactate:

Elevated in cases of bowel ischaemia or infarction due to tissue hypoxia.

Urea and electrolytes (U&Es):

To assess dehydration and electrolyte imbalances due to vomiting and fluid loss.

C-reactive protein (CRP):

Raised in cases of bowel inflammation or infection.

b) Imaging:**Abdominal X-ray:**

First-line imaging modality to diagnose volvulus.

Sigmoid volvulus: Shows a characteristic "coffee bean" or "bent inner tube" sign indicating the twisted loop of bowel.

Caecal volvulus: May show a distended caecum displaced to the left, with air-fluid levels.

CT Abdomen/Pelvis:

Gold standard for diagnosing volvulus, as it provides more detailed information about the location, cause, and extent of obstruction and potential ischaemia.

Can also show the "whirl sign," indicating twisting of the mesentery.

Contrast enema (barium or water-soluble):

Particularly useful in **sigmoid volvulus** as it may reveal the classic "bird's beak" appearance at the site of the twist and can be both diagnostic and therapeutic in some cases.

4. Explanation of Investigations

Abdominal X-ray: Can quickly identify dilated loops of bowel and typical signs like the "coffee bean" sign in sigmoid volvulus or caecal displacement in caecal volvulus.

CT scan: The most accurate imaging tool for diagnosing volvulus and assessing for complications like bowel ischaemia.

Contrast enema: May help in both diagnosing and, in some cases, relieving sigmoid volvulus, especially if it is uncomplicated.

5. Diagnosis Criteria for Volvulus

The diagnosis of volvulus is based on:

Clinical presentation: Symptoms of colicky abdominal pain, distension, vomiting, and obstipation.

Imaging: Classic findings on **abdominal X-ray** (e.g., coffee bean sign) and **CT scan** (whirl sign, twisted bowel loop) confirm the diagnosis.

Contrast enema: The "bird's beak" appearance at the site of torsion helps in confirming sigmoid volvulus.

6. First-Line Therapy According to Guidelines

a) Non-Surgical Management (for uncomplicated sigmoid volvulus):

Endoscopic decompression:

Flexible sigmoidoscopy is the first-line treatment for uncomplicated **sigmoid volvulus**. The twisted segment is untwisted, relieving the obstruction.

Success rates are high (around 70-90%), but the risk of recurrence is also high.

Rectal tube insertion:

After decompression, a rectal tube can be placed to help prevent immediate recurrence of the volvulus.

b) Surgical Management:

Indications for surgery:

Failed endoscopic decompression.

Ischaemia, necrosis, or perforation.

Caecal volvulus typically requires surgery as endoscopic treatment is less effective.

Types of surgery:

Sigmoidectomy: Resection of the twisted sigmoid colon followed by an anastomosis or creation of a **Hartmann's procedure** if there is bowel ischaemia or perforation.

Caecopexy or caecal resection: For caecal volvulus, surgical fixation (caecopexy) or resection of the caecum may be required.

Laparotomy or laparoscopy: Depending on the patient's condition, exploratory laparotomy or laparoscopic surgery may be needed to untwist the bowel or resect necrotic segments.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Endoscopic decompression is contraindicated if there is any sign of bowel ischaemia or perforation, as this increases the risk of complications.

b) Second-Line Therapy:

Elective surgery:

Even after successful endoscopic decompression, elective surgery is recommended to prevent recurrence of sigmoid volvulus, as recurrence rates are high.

Conservative management:

In elderly or frail patients who may not be candidates for surgery, palliative measures such as endoscopic decompression and tube insertion may be repeated.

8. Routine Monitoring and Follow-Up

Post-decompression monitoring:

After successful endoscopic decompression, monitor the patient for signs of **recurrence** or **ischaemia**.

Postoperative monitoring:

For patients who undergo surgery, close monitoring for complications such as **anastomotic leakage, infection, or bowel obstruction** is required.

Electrolyte monitoring:

Regular monitoring of **electrolyte levels** is necessary due to dehydration and fluid loss caused by vomiting and obstruction.

Follow-up imaging:

CT scans or **X-rays** may be required postoperatively to ensure the resolution of the volvulus and assess for any complications.

9. Complications of Volvulus

Bowel ischaemia and necrosis: If volvulus causes strangulation of the blood supply, the affected bowel segment can become necrotic, requiring urgent resection.

Perforation: Prolonged obstruction or ischaemia can lead to bowel perforation, resulting in **peritonitis**.

Recurrence: Even after successful endoscopic decompression, recurrence rates of sigmoid volvulus are high, necessitating definitive surgical management.

Sepsis: If perforation or necrosis occurs, sepsis can develop, leading to septic shock and multiorgan failure.

Summary of Key Points for Volvulus

Volvulus is the twisting of the bowel on its mesentery, leading to bowel obstruction. The most common types are **sigmoid volvulus** and **caecal volvulus**.

Symptoms include sudden onset of colicky abdominal pain, distension, vomiting, and obstipation.

Diagnosis is confirmed with **abdominal X-ray** (coffee bean sign in sigmoid volvulus) and **CT scan**.

First-line treatment for **sigmoid volvulus** is **endoscopic decompression**, but surgical resection is required if decompression fails or if ischaemia, necrosis, or perforation occurs.

Complications include **bowel necrosis**, **perforation**, **peritonitis**, and **sepsis**.

209. Gallstones and Biliary Colic

1. Detailed Definition of Gallstones and Biliary Colic

Gallstones (cholelithiasis) are solid particles that form in the **gallbladder** from bile components such as cholesterol, bilirubin, and calcium salts. These stones can remain in the gallbladder asymptotically or can cause symptoms when they obstruct the **cystic duct** or the **common bile duct**.

Biliary colic refers to episodic, intense pain that occurs when a gallstone temporarily obstructs the **cystic duct**, preventing bile from flowing out of the gallbladder. The term "colic" is a misnomer, as the pain is usually constant rather than colicky.

2. Common Presenting Complaints and Symptoms

Right upper quadrant (RUQ) pain:

Severe, constant pain typically lasting 30 minutes to several hours.

Often radiates to the **right shoulder** or **back** (scapular area).

Pain is triggered by **fatty meals**, as they stimulate bile production and gallbladder contraction.

Nausea and vomiting:

Commonly associated with biliary colic.

No fever or jaundice in uncomplicated biliary colic:

This differentiates biliary colic from complications such as **acute cholecystitis** or **cholangitis**, where fever and jaundice may be present.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Usually normal in biliary colic, but may show leukocytosis if cholecystitis or cholangitis develops.

Liver function tests (LFTs):

Typically normal in biliary colic.

If gallstones migrate into the **common bile duct** (choledocholithiasis), LFTs may show:

Elevated bilirubin.

Elevated alkaline phosphatase (ALP) and gamma-glutamyl transferase (GGT).

Amylase and lipase:

Ordered if **pancreatitis** is suspected, especially if a gallstone obstructs the **pancreatic duct**.

b) Imaging:

Ultrasound of the abdomen:

First-line imaging for diagnosing gallstones.

Sensitivity is high for detecting gallstones in the gallbladder, showing **echogenic foci with acoustic shadowing**.

Can also identify **thickening of the gallbladder wall** or **pericholecystic fluid**, suggestive of cholecystitis.

Magnetic resonance cholangiopancreatography (MRCP):

Non-invasive imaging used to detect stones in the **common bile duct** (choledocholithiasis) if there is concern for **biliary obstruction** or **pancreatitis**.

Endoscopic retrograde cholangiopancreatography (ERCP):

Both diagnostic and therapeutic in cases of **choledocholithiasis**.

ERCP is used when there is a confirmed or strong suspicion of common bile duct stones requiring removal.

CT scan:

Less sensitive than ultrasound for gallstones but may be useful in ruling out other causes of abdominal pain.

4. Explanation of Investigations

Abdominal ultrasound: The best initial test to detect gallstones and assess the gallbladder. It can also detect complications such as gallbladder wall thickening or fluid accumulation.

MRCP: Non-invasive and used to visualise stones in the bile ducts, particularly useful if stones are suspected in the common bile duct.

ERCP: Used for both diagnosis and treatment in cases of choledocholithiasis, allowing stone extraction and biliary drainage.

5. Diagnosis Criteria for Gallstones and Biliary Colic

The diagnosis of gallstones and biliary colic is based on:

Clinical presentation: Right upper quadrant pain following fatty meals, radiating to the shoulder, and lasting several hours.

Imaging: Ultrasound confirmation of gallstones in the gallbladder and normal liver function tests in uncomplicated biliary colic.

Absence of complications: No fever, jaundice, or significant changes in liver enzymes, which would suggest complications like cholecystitis or cholangitis.

6. First-Line Therapy According to Guidelines

a) Initial Management of Biliary Colic:

Pain relief:

Nonsteroidal anti-inflammatory drugs (NSAIDs), such as **diclofenac** or **ibuprofen**, are first-line treatments for biliary colic as they provide effective pain relief and reduce gallbladder inflammation.

Opioids, such as **morphine**, may be required for more severe pain but are used with caution due to their potential to cause sphincter of Oddi spasm.

Antiemetics:

Ondansetron or **metoclopramide** can be used to control nausea and vomiting.

Nil by mouth (NPO):

To rest the gallbladder and reduce symptoms, especially during acute pain episodes.

b) Elective Cholecystectomy:

Laparoscopic cholecystectomy:

The **definitive treatment** for symptomatic gallstones, typically performed **electively** after the acute episode of biliary colic has resolved.

Removing the gallbladder prevents future episodes of biliary colic and reduces the risk of complications (e.g., cholecystitis, pancreatitis).

Laparoscopic cholecystectomy is minimally invasive and has a short recovery time.

c) Management of Complications (e.g., Choledocholithiasis):

ERCP:

If gallstones are present in the common bile duct, **ERCP** can be performed to remove the stones and relieve the obstruction.

Sphincterotomy may be performed to facilitate stone removal.

Antibiotics:

If there is any evidence of infection (e.g., fever, elevated white cell count), antibiotics such as **cefuroxime** or **co-amoxiclav** may be initiated to prevent or treat cholangitis.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery may be delayed in patients with significant comorbidities or poor surgical risk. In such cases, gallbladder drainage via **percutaneous cholecystostomy** can be considered in severe cases.

b) Second-Line Therapy:

Medical dissolution of gallstones:

In patients who are not candidates for surgery, oral **ursodeoxycholic acid** can be used to dissolve cholesterol gallstones, but this is a long-term treatment and only works for specific types of stones.

ERCP:

If stones are suspected in the common bile duct and cannot be managed surgically, **ERCP** with sphincterotomy may be an alternative.

8. Routine Monitoring and Follow-Up

Post-cholecystectomy:

Following elective **laparoscopic cholecystectomy**, patients should be monitored for any signs of infection, bile leakage, or complications from surgery.

Liver function tests:

Should be monitored if there is concern for choledocholithiasis or after ERCP.

Dietary advice:

Patients should avoid large, fatty meals, which can exacerbate biliary colic.

Imaging follow-up:

Rarely required after surgery unless complications arise or stones recur in the common bile duct.

9. Complications of Gallstones and Biliary Colic

Acute cholecystitis: Inflammation of the gallbladder due to persistent cystic duct obstruction. Symptoms include fever, persistent right upper quadrant pain, and Murphy's sign.

Cholangitis: Infection of the bile ducts due to obstruction, leading to **Charcot's triad:** fever, jaundice, and right upper quadrant pain.

Pancreatitis: Gallstones can obstruct the **pancreatic duct**, leading to acute pancreatitis, with severe epigastric pain radiating to the back.

Gallstone ileus: Rarely, large gallstones may erode through the gallbladder wall into the intestine, causing bowel obstruction.

Summary of Key Points for Gallstones and Biliary Colic

Gallstones are solid particles that form in the gallbladder and can cause **biliary colic** when they obstruct the cystic duct.

Symptoms include severe right upper quadrant pain after fatty meals, nausea, and vomiting, with no fever or jaundice in uncomplicated cases.

Diagnosis is confirmed by **abdominal ultrasound**, which detects gallstones and assesses the gallbladder.

Management involves **pain relief** with NSAIDs or opioids, **antiemetics**, and elective **laparoscopic cholecystectomy** for symptomatic patients.

Complications include **acute cholecystitis**, **cholangitis**, and **pancreatitis**, which may require more urgent surgical or endoscopic intervention (e.g., **ERCP**).

210. Gastrointestinal Surgery: Hepatobiliary and Pancreatic Surgery

1. Detailed Definition of Gastrointestinal Surgery (Hepatobiliary and Pancreatic Surgery)

Hepatobiliary and pancreatic (HPB) surgery refers to surgical procedures involving the liver, bile ducts, gallbladder, and pancreas. These surgeries are often complex and are indicated for a

range of benign and malignant conditions affecting these organs. The key types of surgeries in this area include:

Liver resection: Removal of a portion of the liver, often for liver cancer (hepatocellular carcinoma) or liver metastases.

Cholecystectomy: Removal of the gallbladder, typically for symptomatic gallstones or gallbladder cancer.

Biliary surgery: Procedures to address bile duct obstructions, including bile duct resection or reconstruction (choledochal surgeries).

Pancreatic resection: Such as **pancreaticoduodenectomy** (Whipple's procedure) for pancreatic cancer.

2. Common Presenting Complaints and Symptoms

HPB surgery is typically indicated for patients presenting with the following symptoms related to liver, biliary, or pancreatic diseases:

Jaundice:

Yellowing of the skin and eyes due to increased bilirubin, often associated with **biliary obstruction** or **liver disease**.

Abdominal pain:

Typically in the **right upper quadrant** for biliary diseases or the **epigastrium** for pancreatic disorders.

Weight loss and anorexia:

Commonly seen in malignancies of the liver, gallbladder, bile ducts, and pancreas.

Nausea and vomiting:

Related to biliary colic, gallstones, or pancreatic inflammation.

Pruritus (itching):

Common in **cholestatic liver diseases** or **biliary obstructions**.

Ascites:

Accumulation of fluid in the abdomen, seen in **advanced liver disease** or **portal hypertension**.

3. First-Line Investigations

a) Blood Tests:

Liver function tests (LFTs):

Important to assess **bilirubin**, **alanine aminotransferase (ALT)**, **aspartate aminotransferase (AST)**, **alkaline phosphatase (ALP)**, and **gamma-glutamyl transferase (GGT)**. Abnormalities suggest **hepatobiliary dysfunction** or **obstruction**.

Tumour markers:

CA 19-9 for pancreatic and biliary cancers.

Alpha-fetoprotein (AFP) for hepatocellular carcinoma.

Clotting profile:

Prothrombin time (PT) and **international normalised ratio (INR)** to assess liver synthetic function, as the liver produces clotting factors.

Amylase/lipase:

Raised in **acute pancreatitis** and may be indicative of pancreatic inflammation or injury.

b) Imaging:

Ultrasound of the abdomen:

First-line imaging to detect gallstones, bile duct dilation, liver lesions, and pancreatic abnormalities.

Magnetic resonance cholangiopancreatography (MRCP):

Non-invasive imaging to evaluate the biliary tree and pancreas for obstructions or strictures, especially useful in **biliary obstructions**.

Computed tomography (CT) of the abdomen:

Gold standard for staging liver, biliary, and pancreatic malignancies.

Useful in detecting **liver metastases**, **hepatocellular carcinoma**, and **pancreatic tumours**.

Endoscopic retrograde cholangiopancreatography (ERCP):

Both diagnostic and therapeutic. Used for bile duct stones, **choledocholithiasis**, and **biliary stenting**.

4. Explanation of Investigations

Ultrasound: Common first-line imaging to detect gallstones, assess liver parenchyma, and identify biliary obstruction.

MRCP: Provides detailed images of the biliary tree and pancreas without the invasiveness of ERCP.

CT scan: The most comprehensive imaging tool for assessing liver, biliary, and pancreatic lesions, staging malignancies, and planning surgery.

ERCP: Allows direct intervention, such as bile duct stone removal or stent placement, especially in obstructive jaundice.

5. Diagnosis Criteria for Hepatobiliary and Pancreatic Diseases

Diagnosis depends on the underlying condition. For example:

Gallstones: Detected via **ultrasound** with a history of biliary colic.

Hepatocellular carcinoma: Diagnosed via **CT scan** and **AFP levels**.

Pancreatic cancer: Suspected in patients with painless jaundice and weight loss, confirmed via **CT scan** and elevated **CA 19-9**.

Cholangiocarcinoma: Diagnosed through **MRCP** and confirmed via biopsy.

6. First-Line Therapy According to Guidelines

a) Surgical Management:

Liver resection:

Hepatectomy (partial or complete) for **hepatocellular carcinoma** or metastatic disease.

Liver transplantation may be an option for unresectable primary liver tumours or cirrhosis.

Cholecystectomy:

Laparoscopic cholecystectomy is the treatment of choice for symptomatic **gallstones** and **cholecystitis**.

Pancreaticoduodenectomy (Whipple's procedure):

Performed for **pancreatic head cancer** or **periampullary tumours**. This is a complex surgery that involves removing the pancreatic head, duodenum, bile duct, and part of the stomach.

Biliary stenting:

Endoscopic placement of stents to relieve **biliary obstruction** in patients with **cholangiocarcinoma** or **pancreatic cancer**.

b) Non-Surgical Management:

ERCP with stone extraction:

For **choledocholithiasis** (common bile duct stones), ERCP is performed to remove the stones and restore bile flow.

Chemotherapy and radiotherapy:

Used in cases of **inoperable pancreatic cancer**, **cholangiocarcinoma**, or after surgical resection as adjuvant therapy.

Percutaneous drainage:

For **liver abscesses** or **biliary drainage** when surgery is not feasible.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Liver resection: May be contraindicated in patients with **poor liver function** (e.g., advanced cirrhosis), high surgical risk, or extensive metastases.

Surgery for pancreatic cancer: Contraindicated in metastatic or locally advanced tumours involving critical vessels.

b) Second-Line Therapy:

Endoscopic stenting:

For **palliative management** of malignant biliary obstruction.

Non-surgical palliation:

Chemotherapy and **radiotherapy** in patients with inoperable HPB cancers.

8. Routine Monitoring and Follow-Up

Liver function tests (LFTs):

Regular monitoring for patients with liver or biliary disease post-surgery or after ERCP.

Imaging follow-up:

Repeat **CT or MRCP** scans for patients with malignancies to assess for recurrence or progression.

Tumour markers:

Regular monitoring of **AFP** for hepatocellular carcinoma and **CA 19-9** for pancreatic cancer.

Postoperative care:

Close monitoring of surgical patients for signs of infection, bile leakage, or liver failure.

9. Complications of Hepatobiliary and Pancreatic Surgery

Bile leak: Following **cholecystectomy** or liver resection, leading to **biloma** formation or peritonitis.

Pancreatic fistula: Following **Whipple's procedure** or distal pancreatectomy.

Infection: Postoperative wound infections or intra-abdominal abscesses.

Post-ERCP pancreatitis: A potential complication of ERCP.

Liver failure: After extensive liver resection or in patients with underlying liver disease.

Summary of Key Points for Gastrointestinal Surgery (Hepatobiliary and Pancreatic Surgery)

Hepatobiliary and pancreatic surgery involves complex procedures targeting diseases of the liver, bile ducts, gallbladder, and pancreas.

Common symptoms include **jaundice**, **abdominal pain**, **weight loss**, and **pruritus**.

Ultrasound, **CT scans**, **MRCP**, and **ERCP** are key imaging modalities for diagnosing these conditions.

Surgical treatments include **liver resection**, **cholecystectomy**, and **pancreaticoduodenectomy** (Whipple's procedure), while **ERCP** is used for therapeutic intervention in bile duct diseases.

211. Hiatus Hernia

1. Detailed Definition of Hiatus Hernia

A **hiatus hernia** occurs when part of the **stomach** protrudes through the **diaphragmatic hiatus** (the opening in the diaphragm through which the oesophagus passes) into the **thoracic cavity**. There are two main types of hiatus hernia:

Sliding Hiatus Hernia: This is the most common type (about 80-90%) where the gastroesophageal junction and part of the stomach slide up into the chest.

Paraesophageal (Rolling) Hiatus Hernia: Less common but more concerning, as part of the stomach herniates next to the oesophagus while the gastroesophageal junction remains in place.

2. Common Presenting Complaints and Symptoms

Gastro-oesophageal reflux disease (GORD):

Heartburn and **acid regurgitation** are the most common symptoms, especially after meals or when lying down.

Dysphagia (difficulty swallowing):

Occurs in more severe cases, especially if the hernia is large.

Chest pain:

May mimic angina but is related to meals or posture.

Belching and bloating:

Patients often report excessive gas and bloating.

Early satiety:

Feeling full quickly after eating due to the stomach being displaced.

Nausea and vomiting:

Less common but may occur, particularly in cases of **paraesophageal hernia**.

3. First-Line Investigations

a) Blood Tests:

Blood tests are generally **normal** in hiatus hernia unless there are complications such as **oesophagitis** or **iron deficiency anaemia** from chronic blood loss (in severe cases of GORD or oesophagitis).

b) Imaging:

Upper gastrointestinal (GI) endoscopy:

The **gold standard** to confirm the presence of a hiatus hernia and assess for complications such as **oesophagitis**, **Barrett's oesophagus**, or **strictures**.

May show the **gastroesophageal junction** displaced above the diaphragm in **sliding hernia** or part of the stomach alongside the oesophagus in **rolling hernia**.

Barium swallow (Barium oesophagram):

A dynamic study where the patient swallows barium, allowing visualisation of the hernia during fluoroscopy.

Useful in detecting **sliding** or **rolling** hernias and evaluating the oesophagus's motility.

High-resolution manometry:

Assesses **oesophageal motility** and measures the pressure at the **lower oesophageal sphincter (LES)**.

It helps to assess if reflux is due to a weakened LES, which is common in sliding hernias.

24-hour pH monitoring:

Used to confirm **acid reflux** in patients with atypical symptoms or where the diagnosis is unclear after endoscopy.

4. Explanation of Investigations

Upper GI endoscopy: Provides direct visualisation of the oesophagus and stomach to confirm the presence of a hernia and assess any complications such as oesophagitis.

Barium swallow: Allows dynamic assessment of the oesophagus, showing the herniation of the stomach into the thoracic cavity during swallowing.

Manometry: Measures oesophageal motility and helps assess LES function.

pH monitoring: Confirms the presence of acid reflux, especially in patients with GORD symptoms.

5. Diagnosis Criteria for Hiatus Hernia

The diagnosis is based on:

Clinical presentation: Symptoms of heartburn, regurgitation, dysphagia, and chest discomfort, especially after meals or when lying down.

Imaging: Endoscopic or barium studies confirming the displacement of the gastroesophageal junction and/or stomach above the diaphragm.

Manometry and pH monitoring: Support the diagnosis in cases with significant reflux symptoms or atypical presentations.

6. First-Line Therapy According to Guidelines

a) Medical Management:

Lifestyle modifications:

Weight loss if overweight.

Avoiding large meals and lying down after meals.

Elevating the head of the bed to prevent reflux at night.

Avoiding **trigger foods** (e.g., spicy foods, caffeine, alcohol, and fatty meals) that worsen reflux.

Pharmacological therapy:

Proton pump inhibitors (PPIs): First-line treatment for symptom relief, particularly in patients with **GORD** symptoms (e.g., omeprazole, lansoprazole).

Mechanism: PPIs reduce gastric acid secretion by inhibiting the **hydrogen-potassium ATPase enzyme** in the stomach lining.

H2 receptor antagonists (H2RAs): May be used if PPIs are contraindicated or as adjunct therapy (e.g., ranitidine).

Mechanism: H2RAs block histamine receptors in the stomach lining, reducing acid production.

b) Surgical Management:

Indications for surgery:

Failed medical therapy: Persistent symptoms despite optimal PPI therapy.

Complications: Large hernias, recurrent reflux, or oesophagitis not responding to medications.

Paraesophageal hernias: These can cause complications like strangulation and should be surgically corrected.

Laparoscopic fundoplication:

Nissen fundoplication: The most common procedure, where the upper part of the stomach is wrapped around the lower oesophagus to strengthen the **lower oesophageal sphincter (LES)** and prevent reflux.

Partial fundoplication (e.g., Toupet or Dor fundoplication) may be used in patients with weak oesophageal motility.

Hiatal hernia repair:

In **large or paraesophageal hernias**, the hernia is reduced back into the abdomen, and the **hiatus** (diaphragmatic opening) is narrowed surgically to prevent recurrence.

7. Common Contraindications and Second-Line Therapy

a) Contraindications:

Surgery may be contraindicated in patients with significant comorbidities or poor functional status, making them high-risk for anaesthesia or surgery.

b) Second-Line Therapy:

Alternative medical treatments:

If PPIs are poorly tolerated or contraindicated, **H2 receptor antagonists** or **antacids** may provide symptom relief.

Endoscopic therapy:

In some cases, endoscopic techniques such as **radiofrequency ablation** of the LES (Stretta procedure) may be considered to improve sphincter function, though its use is less common.

8. Routine Monitoring and Follow-Up

Symptom monitoring:

Patients on long-term **PPIs** should be monitored for symptom relief and any potential side effects, such as **hypomagnesaemia** or **osteoporosis**.

Endoscopic surveillance:

Patients with **Barrett's oesophagus** or those with **long-standing GORD** may require regular endoscopic surveillance to monitor for dysplasia or malignancy.

Postoperative follow-up:

Following **fundoplication**, patients should be monitored for any complications such as **dysphagia**, **gas-bloat syndrome**, or recurrence of hernia.

9. Complications of Hiatus Hernia

Gastro-oesophageal reflux disease (GORD): A common complication leading to chronic heartburn, regurgitation, and possible oesophagitis.

Oesophagitis: Inflammation of the oesophagus from chronic acid exposure, potentially leading to **strictures**.

Barrett's oesophagus: Metaplasia of the oesophageal lining due to chronic reflux, which increases the risk of oesophageal adenocarcinoma.

Strangulation: Particularly in **paraesophageal hernias**, there is a risk of the herniated stomach becoming strangulated, leading to ischaemia and requiring urgent surgery.

Perforation: In extreme cases, the hernia may perforate, leading to peritonitis and sepsis.

Summary of Key Points for Hiatus Hernia

Hiatus hernia involves the protrusion of the stomach through the diaphragm into the thoracic cavity and is classified as either **sliding** or **paraesophageal**.

Common symptoms include heartburn, regurgitation, chest pain, and dysphagia, often worsened by lying down or after meals.

Diagnosis is confirmed via **endoscopy**, **barium swallow**, or **manometry**, with endoscopy being the gold standard.

First-line treatment involves **lifestyle changes** and **PPIs** for GORD-related symptoms. Surgery, such as **Nissen fundoplication**, is indicated for failed medical therapy or complications.

Complications include GORD, oesophagitis, Barrett's oesophagus, and strangulation in paraesophageal hernias.

212. Colorectal Tumours

1. Detailed Definition of Colorectal Tumours

Colorectal tumours refer to abnormal growths in the **colon** or **rectum**, which can be benign (e.g., polyps) or malignant (colorectal cancer). **Colorectal cancer** (CRC) is one of the most common cancers in the UK and typically arises from **adenomatous polyps** through a sequence of genetic mutations over several years. **Adenocarcinoma** is the most common type of colorectal cancer.

2. Common Presenting Complaints and Symptoms

Change in bowel habits:

May present as **diarrhoea**, **constipation**, or alternating bowel habits.

A **persistent change** in bowel habits, especially in patients over 50, is a red flag for colorectal cancer.

Rectal bleeding:

Patients may notice **bright red** or **dark** blood mixed with stool, often mistaken for haemorrhoids.

Abdominal pain:

Colicky or cramping pain, often associated with **bowel obstruction**, is a common presentation in advanced tumours.

Unexplained weight loss:

A significant, unintentional weight loss is a common sign in malignancies, including colorectal cancer.

Iron-deficiency anaemia:

Caused by **occult bleeding** from the tumour, especially in right-sided colorectal cancers.

Tenesmus:

A constant feeling of needing to pass stool, associated with rectal tumours.

Fatigue:

A common symptom due to chronic blood loss and iron-deficiency anaemia.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

May show **iron-deficiency anaemia** in patients with chronic blood loss, especially in right-sided colon cancers.

Liver function tests (LFTs):

Important in assessing liver metastasis.

Carcinoembryonic antigen (CEA):

A **tumour marker** elevated in some patients with colorectal cancer. CEA is not used for diagnosis but can be useful for monitoring treatment response and recurrence.

b) Imaging and Endoscopy:

Colonoscopy:

Gold standard for diagnosing colorectal cancer. It allows direct visualisation of the tumour and biopsy for histopathological examination.

Flexible sigmoidoscopy may be used if the tumour is located in the rectum or distal colon.

CT Colonography (Virtual colonoscopy):

A non-invasive alternative for patients who are unfit or unwilling to undergo colonoscopy. It uses CT imaging to construct a 3D image of the colon and can detect polyps and tumours.

CT Abdomen and Pelvis:

Often used for **staging** colorectal cancer. It helps assess for **local invasion**, **lymph node involvement**, and distant **metastasis** (especially liver and lungs).

MRI Pelvis:

Used in **rectal cancer** to assess local invasion, particularly into the **mesorectal fascia**, and guide surgical planning.

Positron Emission Tomography (PET-CT):

May be used to assess for metastatic disease in advanced or recurrent colorectal cancer.

4. Explanation of Investigations

Colonoscopy: Allows direct visualisation of the entire colon and rectum and enables biopsy of suspicious lesions. It is the gold standard for detecting colorectal tumours.

CT colonography: A non-invasive imaging modality to detect tumours or polyps, especially in patients unfit for colonoscopy.

CT/MRI: Primarily used to assess tumour staging, lymph node involvement, and metastasis.

CEA: A tumour marker used for monitoring after treatment rather than initial diagnosis.

5. Diagnosis Criteria for Colorectal Tumours

The diagnosis of colorectal cancer is based on:

Colonoscopy with **biopsy** confirming adenocarcinoma or other histopathological subtypes.

CT/MRI staging: Helps assess the tumour (T), node (N), and metastasis (M) status based on the **TNM staging system**.

CT/PET may be used to detect metastatic spread, particularly to the liver and lungs.

6. First-Line Therapy According to Guidelines

a) Surgical Management:

Curative surgery:

Resection of the tumour is the mainstay of treatment for non-metastatic colorectal cancer. The specific type of surgery depends on the tumour's location:

Right hemicolectomy for right-sided colon cancer.

Left hemicolectomy for left-sided colon cancer.

Sigmoid colectomy for sigmoid colon cancer.

Anterior resection or **abdominoperineal resection (APR)** for rectal cancer, depending on the tumour's distance from the anal verge.

Total mesorectal excision (TME) is used for rectal cancer to ensure the complete removal of the tumour and surrounding lymphatic tissue.

Laparoscopic or open surgery:

Laparoscopic surgery is increasingly preferred due to faster recovery times, but open surgery may be necessary in more complex cases.

Stoma formation:

Some patients may require a **temporary** or **permanent stoma** (e.g., colostomy or ileostomy), especially after surgery for rectal cancer.

b) Chemotherapy and Radiotherapy:**Adjuvant chemotherapy:**

Indicated in patients with **stage III** disease (node-positive) or **high-risk stage II** colorectal cancer.

Common regimens include **FOLFOX** (5-fluorouracil, leucovorin, oxaliplatin) or **CAPOX** (capecitabine, oxaliplatin).

Neoadjuvant radiotherapy:

Often used in **locally advanced rectal cancer** to shrink the tumour before surgery and reduce the risk of local recurrence.

Chemoradiotherapy:

In patients with rectal cancer, **chemoradiotherapy** may be used before surgery to improve resectability and outcomes.

7. Common Contraindications and Second-Line Therapy**a) Contraindications:**

Surgery may be contraindicated in patients with extensive metastatic disease or poor functional status that makes them unfit for surgery.

b) Second-Line Therapy:**Palliative chemotherapy:**

For patients with metastatic colorectal cancer, chemotherapy with drugs like **5-fluorouracil**, **capecitabine**, **oxaliplatin**, or **irinotecan** may be used to prolong survival and relieve symptoms.

Targeted therapy:

Bevacizumab (anti-VEGF) or **cetuximab** (anti-EGFR) may be used in patients with metastatic colorectal cancer, particularly if they have specific genetic mutations like **KRAS wild-type**.

Palliative care:

In patients with advanced disease, focus shifts towards symptom control, managing complications such as bowel obstruction, and providing end-of-life care.

8. Routine Monitoring and Follow-Up

CEA monitoring:

CEA levels should be monitored every 3-6 months post-surgery to detect early recurrence.

Colonoscopy:

Surveillance colonoscopy is recommended 1 year after surgery and every 3-5 years thereafter, depending on findings.

Imaging follow-up:

CT scans of the chest, abdomen, and pelvis are typically done every 6-12 months for 5 years after surgery to monitor for recurrence or metastasis.

Liver function tests (LFTs):

Regular LFTs are important to monitor for liver metastases, especially in patients with advanced disease.

9. Complications of Colorectal Tumours and Surgery

Bowel obstruction: Tumours can cause partial or complete obstruction, requiring urgent surgical intervention.

Perforation: Tumours can perforate the bowel wall, leading to peritonitis and sepsis.

Anastomotic leakage: A potential complication after bowel resection, particularly in patients who undergo low anterior resection for rectal cancer.

Recurrence: Colorectal cancer can recur locally or metastasise to the liver or lungs.

Stoma-related complications: Patients with colostomies or ileostomies may experience skin irritation, stoma retraction, or infection.

Summary of Key Points for Colorectal Tumours

Colorectal cancer is a common malignancy that often arises from adenomatous polyps and presents with changes in bowel habits, rectal bleeding, and unexplained weight loss.

Diagnosis is made via **colonoscopy**, and staging is determined using **CT/MRI**.

First-line treatment is **surgical resection**, with chemotherapy and/or radiotherapy used in high-risk cases or for rectal cancer.

Surveillance includes monitoring CEA levels, regular colonoscopy, and imaging to detect recurrence.

Complications include **bowel obstruction**, **perforation**, and postoperative complications like anastomotic leakage.

213. Inflammatory Bowel Disease (IBD)

1. Detailed Definition of Inflammatory Bowel Disease

Inflammatory Bowel Disease (IBD) is a group of chronic inflammatory conditions primarily affecting the gastrointestinal (GI) tract. The two main types of IBD are:

Ulcerative Colitis (UC): Affects the **colon** and **rectum**, characterised by continuous inflammation starting from the rectum and extending proximally, with inflammation confined to the mucosa and submucosa.

Crohn's Disease (CD): Can affect any part of the **GI tract** from the mouth to the anus, characterised by **skip lesions** with transmural inflammation (affecting the full thickness of the bowel wall).

2. Common Presenting Complaints and Symptoms

Ulcerative Colitis (UC):

Bloody diarrhoea:

Often with mucus, occurring frequently with a sense of urgency.

Abdominal pain:

Typically **lower left quadrant** pain, especially during flare-ups.

Tenesmus:

A sensation of incomplete evacuation or the urge to defecate.

Systemic symptoms:

Weight loss, fever, and fatigue in severe cases.

Crohn's Disease (CD):

Diarrhoea:

May be non-bloody and associated with urgency or steatorrhoea (fatty stools).

Abdominal pain:

Usually **right lower quadrant** pain due to ileal involvement.

Weight loss and malnutrition:

Due to malabsorption, especially if the small bowel is involved.

Fistulas and abscesses:

Perianal disease with fistulas, abscesses, and skin tags are common in Crohn's.

Systemic symptoms:

Fever, fatigue, and anorexia.

3. First-Line Investigations

a) Blood Tests:

Full Blood Count (FBC):

Anaemia (due to chronic blood loss in UC or malabsorption in Crohn's), **leucocytosis** in active disease, and **thrombocytosis**.

C-reactive protein (CRP) and Erythrocyte sedimentation rate (ESR):

Raised in active inflammation, useful for monitoring disease activity.

Liver function tests (LFTs):

May show **raised alkaline phosphatase** (ALP) in patients with **primary sclerosing cholangitis**, associated with UC.

Iron studies, Vitamin B12, and Folate:

To assess for **iron deficiency** and **vitamin B12** or **folate deficiencies**, especially in Crohn's involving the ileum.

b) Stool Tests:

Faecal calprotectin:

A sensitive marker of intestinal inflammation used to distinguish IBD from **irritable bowel syndrome (IBS)**. Elevated levels indicate active disease.

Stool cultures:

To exclude **infectious colitis** (e.g., bacterial infections like *Clostridium difficile*) that may mimic IBD symptoms.

c) Imaging and Endoscopy:

Colonoscopy with biopsy:

Gold standard for diagnosing IBD. In **UC**, it shows continuous inflammation starting from the rectum. In **CD**, it reveals skip lesions and may show transmural inflammation.

Biopsies help confirm the diagnosis and differentiate between UC and Crohn's disease.

Magnetic Resonance Enterography (MRE) or CT enterography:

Non-invasive imaging techniques used in Crohn's disease to assess small bowel involvement, strictures, and fistulas.

Barium enema:

Rarely used now but may show a **lead-pipe appearance** in UC due to loss of haustration and **string sign** in Crohn's due to bowel wall thickening and strictures.

4. Explanation of Investigations

Colonoscopy: Allows direct visualisation of the colon and rectum to assess the extent and severity of inflammation. Biopsies help differentiate between UC and Crohn's.

Faecal calprotectin: A non-invasive test that measures inflammation in the intestines, helpful in distinguishing IBD from functional disorders like IBS.

MRE/CT enterography: Imaging used to assess small bowel involvement in Crohn's disease, particularly useful for detecting strictures and fistulas.

5. Diagnosis Criteria for Inflammatory Bowel Disease

Diagnosis is based on a combination of **clinical presentation, endoscopic findings, histology, and imaging.**

Ulcerative Colitis:

Colonoscopy: Continuous inflammation starting from the rectum.

Histology: Crypt abscesses, goblet cell depletion, and mucosal inflammation.

Faecal calprotectin: Elevated, confirming intestinal inflammation.

Crohn's Disease:

Colonoscopy: Skip lesions, aphthous ulcers, and cobblestoning of the mucosa.

Histology: Transmural inflammation, granulomas (non-caseating), and deep ulcers.

Imaging (MRE/CT): Bowel wall thickening, strictures, and fistulas.

6. First-Line Therapy According to Guidelines

Ulcerative Colitis (UC):

Mild to moderate disease:

Aminosalicylates (5-ASAs): First-line therapy for inducing and maintaining remission (e.g., mesalazine).

Mechanism: Anti-inflammatory effects targeting the colonic mucosa.

Moderate to severe disease:

Corticosteroids: Used for acute flare-ups (e.g., **prednisolone**).

Mechanism: Potent anti-inflammatory effects by suppressing immune response.

Immunosuppressants:

Azathioprine or 6-mercaptopurine: Used for steroid-sparing and maintaining remission in patients with frequent relapses.

Biologic therapy:

Anti-TNF agents (e.g., **infliximab**, **adalimumab**) or **anti-integrin agents** (e.g., **vedolizumab**) in patients who are refractory to conventional therapy.

Crohn's Disease (CD):

Mild to moderate disease:

Budesonide: A glucocorticoid with a lower systemic side effect profile, particularly for **ileal or right-sided colonic Crohn's**.

Moderate to severe disease:

Corticosteroids (e.g., **prednisolone**) for acute flares.

Immunosuppressants:

Azathioprine, **6-mercaptopurine**, or **methotrexate**: Used for maintaining remission.

Biologic therapy:

Anti-TNF agents (e.g., **infliximab**, **adalimumab**) or **anti-integrin agents** for patients with moderate to severe disease not responding to conventional treatment.

Antibiotics:

Metronidazole or **ciprofloxacin**: Used for **perianal Crohn's disease** or fistulas.

7. Common Contraindications and Second-Line Therapy

Contraindications:

Aminosalicylates: Contraindicated in patients with **sulfa allergies**.

Immunosuppressants: Contraindicated in patients with **active infections** or **severe immunosuppression**.

Second-Line Therapy:

Biologic therapies:

In patients who do not respond to first-line biologics, **anti-integrin agents** (e.g., **vedolizumab**) or **anti-IL-12/23 agents** (e.g., **ustekinumab**) may be used.

Surgery:

Surgery is more commonly indicated in **Crohn's disease**, particularly for complications like **strictures**, **fistulas**, and **abscesses**. In **UC**, **colectomy** may be performed in severe, refractory cases.

8. Routine Monitoring and Follow-Up

Blood monitoring:

Regular monitoring of **FBC**, **CRP**, and **liver function** in patients on **immunosuppressants** and **biologics** to detect adverse effects or treatment failure.

Endoscopic surveillance:

Patients with long-standing UC or Crohn's colitis (>8-10 years) require **regular colonoscopies** to screen for **colorectal cancer**.

Bone health:

Long-term steroid use can lead to **osteoporosis**, so **DEXA scans** and **calcium/vitamin D** supplementation may be required.

9. Complications of Inflammatory Bowel Disease

Fistulas (in Crohn's disease): Abnormal connections between the bowel and other structures (e.g., bladder, skin).

Strictures (more common in Crohn's): Narrowing of the bowel, potentially leading to bowel obstruction.

Toxic megacolon (more common in UC): Acute colonic dilation with risk of perforation and sepsis.

Colorectal cancer: Increased risk in long-standing IBD, particularly in UC.

Malabsorption: Particularly in Crohn's involving the small intestine, leading to nutritional deficiencies.

Summary of Key Points for Inflammatory Bowel Disease

IBD encompasses **ulcerative colitis** and **Crohn's disease**, with symptoms of diarrhoea, abdominal pain, and weight loss.

Diagnosis is confirmed by **colonoscopy** and **biopsy**, with imaging like **MRE** used to assess small bowel disease in Crohn's.

First-line treatment involves **aminosalicylates** for UC and **corticosteroids** for acute flares in both conditions, with **immunosuppressants** and **biologics** for maintenance in severe cases.

Complications include **fistulas**, **strictures**, **toxic megacolon**, and increased risk of **colorectal cancer**.

214. Anal Fissure

1. Detailed Definition of Anal Fissure

An **anal fissure** is a small tear or ulcer in the **anoderm** (lining of the anus) located at or just inside the **anal canal**. Fissures are typically found in the **posterior midline**, but may occasionally occur in the anterior midline. Anal fissures are classified as **acute** (lasting less than 6 weeks) or **chronic** (lasting more than 6 weeks).

2. Common Presenting Complaints and Symptoms

Sharp anal pain:

The hallmark of an anal fissure, often described as a **tearing** or **cutting** pain during or immediately after defecation.

Bleeding:

Bright red **rectal bleeding** (haematochezia), typically seen on the toilet paper or surface of the stool, not mixed with the stool.

Spasms of the anal sphincter:

Patients may report **prolonged aching** after defecation, caused by spasm of the **internal anal sphincter**.

Itching and irritation:

Associated with chronic fissures.

3. First-Line Investigations

a) Clinical Examination:

Visual inspection of the anal region:

This is usually sufficient to diagnose an anal fissure, revealing a small tear in the anoderm.

Most fissures are located in the **posterior midline**, with **chronic fissures** showing signs of **sentinel skin tags** or **hypertrophied anal papilla**.

b) Digital Rectal Examination (DRE):

DRE is usually avoided due to the extreme pain it causes during acute fissures. However, in chronic cases, careful DRE may be performed to assess for other underlying conditions.

c) Endoscopic Evaluation:

Proctoscopy or sigmoidoscopy:

Rarely required unless there are concerns about **alternative diagnoses** (e.g., inflammatory bowel disease, rectal cancer) or if the fissure is **atypically located** (e.g., lateral).

d) Blood tests:

Full blood count (FBC):

May be performed to check for **anaemia** if significant bleeding is present (though uncommon in simple anal fissures).

4. Explanation of Investigations

Visual inspection: Most commonly used to identify the location and appearance of the fissure, especially if in the posterior midline.

Proctoscopy/sigmoidoscopy: Recommended if there are atypical features (e.g., lateral fissures) to rule out conditions like Crohn's disease or malignancy.

5. Diagnosis Criteria for Anal Fissure

The diagnosis is made primarily through **clinical examination**:

Acute fissures appear as fresh tears or ulcers in the **posterior midline**.

Chronic fissures may show signs of **fibrosis**, **hypertrophied anal papillae**, or **sentinel skin tags**.

Atypical fissures (e.g., lateral fissures) may warrant further investigation to rule out underlying causes such as **inflammatory bowel disease**, **HIV**, **syphilis**, or **anal carcinoma**.

6. First-Line Therapy According to Guidelines

a) Conservative Management:

Dietary modifications:

High-fibre diet (20-35 grams/day) to soften stools and prevent straining during defecation.

Increased fluid intake to avoid constipation.

Stool softeners and laxatives:

Lactulose or **polyethylene glycol (PEG)** may be prescribed to maintain soft, easy-to-pass stools and prevent further trauma to the fissure.

Topical treatments:

Topical anaesthetics (e.g., **lidocaine**) for pain relief.

Topical vasodilators:

Glyceryl trinitrate (GTN) 0.2% ointment: First-line topical treatment for acute and chronic fissures.

Mechanism: Relaxes the **internal anal sphincter** and improves blood flow to the fissure, promoting healing.

Diltiazem 2% ointment: Another effective option if GTN is not tolerated (e.g., due to headaches).

Mechanism: A calcium channel blocker that reduces anal sphincter spasm and improves healing.

b) Surgical Management:

Lateral internal sphincterotomy (LIS):

Recommended for patients with **chronic fissures** or those who do not respond to medical treatment.

Mechanism: Involves cutting a portion of the **internal anal sphincter** to relieve the spasm and allow the fissure to heal.

Botulinum toxin (Botox) injection:

Can be considered for patients who fail to respond to topical treatment but want to avoid surgery.

Mechanism: Relaxes the sphincter, reducing spasm and pain, promoting healing of the fissure.

7. Common Contraindications and Second-Line Therapy

Contraindications:

Topical glyceryl trinitrate (GTN):

Contraindicated in patients with a history of **migraine** or severe **headaches**, as it may exacerbate these conditions.

Second-Line Therapy:

Topical diltiazem:

If **GTN** is not tolerated, **diltiazem 2% ointment** can be used as an alternative.

Botox injection:

An alternative to surgery, particularly in patients who are high-risk for surgery or want to avoid **lateral internal sphincterotomy**.

8. Routine Monitoring and Follow-Up

Patients using **topical GTN** or **diltiazem** should be reviewed after **6-8 weeks** to assess symptom relief and healing of the fissure.

If symptoms persist despite conservative management, referral for **surgical intervention** (e.g., sphincterotomy) may be required.

Recurrence is common, and patients should be educated on maintaining a high-fibre diet and adequate hydration to avoid constipation and recurrence.

9. Complications of Anal Fissure

Chronic fissure formation:

An untreated acute fissure may progress to chronic fissure formation with **hypertrophic skin tags** and **fibrosis**, making healing more difficult.

Sentinel skin tag:

A hypertrophied anal skin tag that can develop in chronic fissures, causing further irritation.

Abscess formation:

Rare but possible if an anal fissure becomes infected.

Recurrence:

Even after healing, anal fissures can recur, particularly if constipation or hard stools return.

Summary of Key Points for Anal Fissure

Anal fissure is a tear in the anal canal, typically caused by trauma from hard stools, straining, or constipation.

Common symptoms include severe pain during and after defecation, bright red bleeding, and sphincter spasms.

First-line treatment includes dietary changes, stool softeners, and topical therapies (GTN or diltiazem).

Surgical intervention (lateral internal sphincterotomy) is reserved for chronic fissures or cases resistant to medical therapy.

Complications include **chronic fissures**, **sentinel skin tags**, and **recurrence**.

215. Haemorrhoids

1. Detailed Definition of Haemorrhoids

Haemorrhoids, also known as **piles**, are swollen and inflamed vascular structures in the **anal canal**. They can occur **internally** (inside the rectum, above the dentate line) or **externally** (below the dentate line, around the anus). Haemorrhoids are classified based on their position and severity:

Internal haemorrhoids: Classified into four grades based on the degree of prolapse:

Grade I: No prolapse, just prominent blood vessels.

Grade II: Prolapse during straining but spontaneously reduce.

Grade III: Prolapse during straining and require manual reduction.

Grade IV: Prolapse and cannot be manually reduced.

External haemorrhoids: Occur under the skin around the anus and are often associated with pain due to the somatic innervation of this region.

2. Common Presenting Complaints and Symptoms

Rectal bleeding:

Bright red blood on the stool, toilet paper, or in the toilet bowl. Bleeding is painless and often noticed after defecation.

Prolapse:

A palpable or visible lump or swelling from the anus, especially with Grade III and IV haemorrhoids.

Discomfort or itching:

Internal haemorrhoids are often painless unless thrombosed. **External haemorrhoids** can cause pain, itching, and irritation around the anus.

Pain:

External haemorrhoids can be painful, especially if thrombosed (clot formation within the haemorrhoid), leading to severe, sharp pain.

Mucus discharge:

May cause soiling and irritation, commonly associated with Grade III or IV haemorrhoids.

3. First-Line Investigations

a) Clinical Examination:

Visual inspection:

Look for external haemorrhoids, prolapse, and skin tags.

Digital Rectal Examination (DRE):

Helps assess the presence of internal haemorrhoids, but may not always be conclusive.

Proctoscopy:

A short examination using a proctoscope allows direct visualisation of internal haemorrhoids to assess size, location, and grade.

b) Blood Tests:

Full Blood Count (FBC):

May be done if there is a history of **significant rectal bleeding** to check for **anaemia**.

c) Other investigations:

Colonoscopy or flexible sigmoidoscopy:

Performed if there are **red flag symptoms** (e.g., weight loss, iron-deficiency anaemia, or a change in bowel habits) or if there is concern for **colorectal cancer**. Not routine for uncomplicated haemorrhoids.

4. Explanation of Investigations

Proctoscopy: A simple and essential tool for the visualisation of **internal haemorrhoids** to assess the severity and determine the appropriate treatment approach.

Colonoscopy: Recommended if there are **alarm symptoms** like significant rectal bleeding or changes in bowel habits to rule out other conditions like **colorectal cancer**.

5. Diagnosis Criteria for Haemorrhoids

The diagnosis of haemorrhoids is primarily clinical, based on **symptoms** (e.g., bleeding, prolapse, pain) and confirmed by **physical examination** (including **proctoscopy**). Diagnostic criteria include:

Internal haemorrhoids: Based on **prolapse** and the degree to which haemorrhoids can be manually reduced.

External haemorrhoids: Identified by **visual inspection** or **palpation** of a painful, swollen lump around the anus.

6. First-Line Therapy According to Guidelines

a) Conservative Management:

Dietary modifications:

High-fibre diet: Encourages soft stools to reduce straining during defecation. Recommend 20-30 grams of fibre daily from fruits, vegetables, and whole grains.

Increased fluid intake: Adequate hydration helps soften stools and prevents constipation.

Stool softeners:

Laxatives (e.g., **lactulose**, **polyethylene glycol (PEG)**) to prevent constipation and reduce straining.

Topical treatments:

Topical anaesthetics (e.g., **lidocaine**) for symptomatic relief.

Topical corticosteroids (e.g., **hydrocortisone**) for reducing inflammation and swelling, typically used for a short duration to avoid skin thinning.

Sitz baths:

Soaking the anal area in warm water several times a day (especially after bowel movements) helps relieve pain and swelling.

b) Non-Surgical Minimally Invasive Treatments:

Rubber band ligation:

First-line for **Grade II and III** internal haemorrhoids. A rubber band is placed around the base of the haemorrhoid, cutting off its blood supply, leading to necrosis and sloughing off.

Sclerotherapy:

Injection of a sclerosing agent into the haemorrhoid to shrink it, typically used for **Grade I and II** haemorrhoids.

Infrared coagulation:

A treatment that uses infrared light to coagulate the haemorrhoidal tissue, used for **early-stage haemorrhoids**.

c) Surgical Management:

Haemorrhoidectomy:

Indicated for **Grade III and IV** haemorrhoids or if other therapies have failed.

Traditional open haemorrhoidectomy involves excision of the haemorrhoidal tissue and is effective for large or prolapsed haemorrhoids.

Stapled haemorrhoidopexy:

Used for **Grade III haemorrhoids**. It involves the resection of prolapsed mucosa and submucosa to reposition the haemorrhoids and reduce prolapse.

7. Common Contraindications and Second-Line Therapy

Contraindications:

Topical steroids:

Prolonged use should be avoided as it can lead to **skin atrophy**.

Rubber band ligation:

Not suitable for **external haemorrhoids** or in patients with **anticoagulation therapy**.

Second-Line Therapy:

Haemorrhoidectomy:

For patients with **Grade IV haemorrhoids**, recurrent haemorrhoids, or those who fail to respond to conservative measures and non-surgical treatments.

Stapled haemorrhoidopexy:

An alternative to traditional haemorrhoidectomy for Grade III haemorrhoids, offering faster recovery times but a higher risk of recurrence.

8. Routine Monitoring and Follow-Up

Follow-up is essential after treatment to assess symptom resolution. Patients undergoing **rubber band ligation** should have a follow-up after **4-6 weeks** to evaluate the success of the procedure.

Dietary advice and **stool softeners** should be continued long-term to prevent recurrence.

For **surgical patients**, follow-up is required to monitor for complications such as **anal stenosis**, **infection**, or **recurrence**.

9. Complications of Haemorrhoids

Thrombosed external haemorrhoids:

Can cause acute severe pain due to clot formation. Treatment may involve **incision and drainage** if symptoms are significant.

Anaemia:

Chronic rectal bleeding can lead to **iron-deficiency anaemia**, especially in untreated or recurrent haemorrhoids.

Strangulated haemorrhoids:

Rare, but occur when prolapsed haemorrhoids become trapped outside the anus, leading to **impaired blood supply** and possible **gangrene**.

Recurrence:

Common, especially if **dietary changes** and **lifestyle modifications** are not maintained.

Summary of Key Points for Haemorrhoids

Haemorrhoids are common, presenting with **rectal bleeding**, **itching**, and **pain** in external haemorrhoids.

Internal haemorrhoids are classified into four grades, with treatment ranging from conservative management for **Grade I** to **surgical haemorrhoidectomy** for **Grade IV**.

Rubber band ligation and **sclerotherapy** are effective first-line minimally invasive treatments for **Grade II and III haemorrhoids**.

Surgical options include **haemorrhoidectomy** and **stapled haemorrhoidopexy** for advanced or recurrent haemorrhoids.

Preventing recurrence through dietary changes, fibre supplements, and maintaining soft stools is crucial.

216. Perianal Abscesses and Fistulae

1. Detailed Definition of Perianal Abscesses and Fistulae**Perianal Abscess:**

A **collection of pus** in the perianal region resulting from infection of the anal glands located in the intersphincteric space. It presents as a **painful swelling** near the anus and may be superficial or deep.

Perianal Fistula:

A chronic abnormal connection (tract) between the **anoderm** (lining of the anal canal) and the **perianal skin**, often resulting from the drainage of a perianal abscess. Fistulae can be classified based on their location relative to the anal sphincter:

Intersphincteric (most common)

Transsphincteric

Suprasphincteric

Extrasphincteric

2. Common Presenting Complaints and Symptoms

Perianal Abscess:

Severe perianal pain:

Typically constant, throbbing, and worsened by movement or sitting.

Swelling:

A tender, swollen lump near the anus, which may be red and fluctuant.

Fever:

Systemic signs of infection, including fever, malaise, and fatigue.

Discharge:

If the abscess spontaneously drains, patients may notice a **purulent discharge** from the anus.

Perianal Fistula:

Persistent purulent discharge:

Chronic discharge of **pus** or **faeces** through an external opening near the anus.

Recurrent abscess formation:

A history of previous **abscess drainage** with recurrent infections.

Pain:

Dull pain, irritation, or discomfort in the perianal area.

Swelling:

A **palpable cord-like structure** (the fistula tract) may be felt on examination.

3. First-Line Investigations

a) Clinical Examination:

Inspection:

Look for **external openings** (fistula) or visible **perianal swelling** (abscess).

Palpation of a **tender, fluctuant mass** suggests an abscess.

Digital Rectal Examination (DRE):

May reveal a deep abscess if not visible externally.

Fistula tracts may be felt as **fibrotic cords**.

b) Imaging:

Magnetic Resonance Imaging (MRI):

Gold standard for diagnosing complex fistulae. MRI helps delineate the fistula tract and assess involvement of the **anal sphincters**.

Endoanal Ultrasound:

Useful for identifying **simple fistulae** and abscesses, especially when MRI is unavailable.

CT scan:

May be used in cases of **deep or recurrent abscesses** to assess for complex infections.

c) Fistulography:

An **X-ray study** performed by injecting contrast material into the fistula tract. This is now rarely used due to the superior imaging modalities available (MRI).

d) Blood Tests:

Full blood count (FBC):

Look for **leukocytosis**, indicating infection.

CRP and ESR:

Raised in cases of active infection and inflammation.

4. Explanation of Investigations

MRI: Provides detailed images of the **fistula tract**, showing its relationship to the sphincters and any branching, making it essential for surgical planning.

Endoanal ultrasound: Useful for assessing **internal openings** and the involvement of the sphincters in **simple fistulae**.

Blood tests: Help in identifying the severity of infection and systemic involvement.

5. Diagnosis Criteria for Perianal Abscesses and Fistulae

Perianal Abscess:

Diagnosed through **clinical findings** of a **painful, fluctuant mass** in the perianal region, often with associated fever or systemic signs of infection.

Perianal Fistula:

Diagnosis is confirmed through:

Clinical examination revealing a tract or **discharge** from an external opening.

Imaging (MRI or endoanal ultrasound) showing the **fistula tract** and its relationship to the anal sphincter muscles.

6. First-Line Therapy According to Guidelines

a) Perianal Abscess:

Surgical drainage:

Incision and drainage (I&D) is the first-line treatment for all perianal abscesses.

This is usually performed under local or general anaesthesia depending on the extent of the abscess.

Antibiotics:

Generally not required for uncomplicated abscesses following drainage.

Indicated in patients with:

Systemic signs of infection (fever, chills).

Immunocompromised states (e.g., diabetes, HIV).

Recurrent abscesses or **cellulitis**.

b) Perianal Fistula:

Fistulotomy:

The **gold standard** for treating simple **intersphincteric** and **low transsphincteric** fistulae.

Involves opening the fistula tract and allowing it to heal by secondary intention.

Seton placement:

Used for **complex or high fistulae** to preserve sphincter function and prevent incontinence.

A **Seton** (a surgical thread or wire) is placed through the fistula tract to allow for gradual drainage and fibrosis of the tract.

LIFT procedure (Ligation of Intersphincteric Fistula Tract):

Minimally invasive procedure, particularly useful for **complex fistulae** involving a significant portion of the sphincter muscle.

The fistula tract is **ligated** and excised, sparing the sphincter.

Fibrin glue or bioprosthetic plugs:

These are **sphincter-sparing techniques** for low fistulae, but have a **higher recurrence rate** compared to surgical options.

7. Common Contraindications and Second-Line Therapy

Contraindications:

Fistulotomy:

Contraindicated in **complex high fistulae** as it carries a risk of **faecal incontinence**.

Second-Line Therapy:

Seton placement for complex fistulae to allow gradual healing while preserving sphincter function.

LIFT procedure: Preferred for complex and high fistulae as a sphincter-preserving technique.

8. Routine Monitoring and Follow-Up

Perianal abscess:

Follow-up after **incision and drainage** is essential to ensure the abscess has resolved and that there is no **fistula formation**.

Perianal fistula:

Regular follow-up post-surgery to monitor for **healing, recurrence**, and ensure **continence** is preserved.

MRI or **endoanal ultrasound** may be repeated in recurrent cases or when healing is delayed.

9. Complications of Perianal Abscesses and Fistulae

Perianal Abscess:**Fistula formation:**

Occurs in up to **50%** of patients following abscess drainage if the infection extends into the anal glands.

Sepsis:

Rare but serious, especially in immunocompromised patients if the infection spreads systemically.

Recurrent abscess:

May require further drainage or investigation for an underlying fistula.

Perianal Fistula:**Faecal incontinence:**

A complication of fistulotomy, especially in **high transsphincteric fistulae** if too much of the sphincter is divided.

Recurrence:

Common, especially in **complex fistulae** or if the primary surgery did not completely remove the fistula tract.

Perianal abscess:

Fistulae may re-abscess if the tract becomes blocked.

Summary of Key Points for Perianal Abscesses and Fistulae

Perianal abscesses present with **painful swelling**, and treatment involves **surgical drainage**. Antibiotics are used only in selected cases.

Perianal fistulae often result from **drained abscesses** and present with **persistent discharge**. **Fistulotomy** is the standard treatment, with more complex cases managed with **Seton placement** or the **LIFT procedure**.

MRI is the **gold standard** for imaging complex fistulae.

Regular follow-up is essential to ensure **healing** and prevent **recurrence** or **incontinence**.

217. Hernias

1. Detailed Definition of Hernias

A **hernia** is the **protrusion of an organ or tissue** through a weakness or defect in the muscular wall that normally contains it. The most common types of hernias include:

Inguinal hernia: Occurs in the groin, where the intestine or abdominal fat protrudes through the inguinal canal. It can be **indirect** (through the internal inguinal ring) or **direct** (through a weakness in the posterior wall of the inguinal canal).

Femoral hernia: Occurs when abdominal contents protrude through the femoral canal, beneath the inguinal ligament. More common in women.

Umbilical hernia: Protrusion of abdominal contents through the umbilical ring.

Incisional hernia: Occurs through a defect at the site of a previous surgical incision.

Hiatal hernia: Protrusion of part of the stomach through the diaphragm into the thoracic cavity.

2. Common Presenting Complaints and Symptoms

Visible or palpable bulge:

Typically found in the **groin, abdomen, or near a previous surgical scar**.

The bulge may **increase in size** with activities like coughing, lifting, or standing.

Pain or discomfort:

The hernia may cause **aching** or **sharp pain**, particularly after exertion.

The pain is often worse with **activity** and **improves** with rest or lying down.

Nausea and vomiting:

Signs of bowel obstruction if the hernia becomes strangulated or obstructed.

Symptoms specific to hiatal hernia:

Heartburn or **reflux** symptoms.

Difficulty swallowing (**dysphagia**) due to herniation of the stomach into the chest.

3. First-Line Investigations

a) Clinical Examination:

Inspection:

Look for **visible bulge** in areas where hernias are common (e.g., groin, umbilicus, previous scars).

Palpation:

Ask the patient to **stand** and **cough** or perform a **Valsalva manoeuvre** to assess for a palpable mass.

Reducibility:

Check whether the hernia is **reducible** (can be pushed back into the abdomen) or **irreducible** (indicating a possible incarcerated hernia).

b) Imaging:

Ultrasound:

Useful for diagnosing **inguinal**, **femoral**, and **umbilical hernias**. It can help differentiate between **inguinal** and **femoral hernias**, especially in women.

CT scan:

Provides a more detailed evaluation of **incisional hernias** or **recurrent hernias**. Also used for diagnosing **complicated hernias** (e.g., strangulation, bowel obstruction).

Barium swallow or endoscopy:

Used in the diagnosis of **hiatal hernia** to assess the size and extent of herniation.

c) Blood tests:

Full blood count (FBC):

To assess for **leukocytosis**, which may indicate infection or inflammation in the case of a **strangulated hernia**.

Lactate:

Elevated levels may suggest **bowel ischaemia** in cases of strangulated hernia.

4. Explanation of Investigations

Ultrasound: A non-invasive and first-line imaging modality, especially useful in diagnosing **inguinal and femoral hernias**, as well as distinguishing between hernia types.

CT scan: More detailed, helps in complex or **recurrent hernias**, and identifies complications like bowel strangulation or obstruction.

5. Diagnosis Criteria for Hernias

Clinical examination remains the cornerstone of diagnosis. A **palpable bulge** that increases with **straining** or **coughing** confirms the diagnosis of most hernias.

Imaging, such as **ultrasound** or **CT scan**, is used when the hernia is not palpable or to assess complications (e.g., strangulation, obstruction).

6. First-Line Therapy According to Guidelines

a) Conservative Management:

Watchful waiting:

Appropriate for **asymptomatic** or **minimally symptomatic** inguinal hernias, particularly in **older patients** or those with significant comorbidities who are not suitable candidates for surgery.

b) Surgical Management:

Elective hernia repair:

Inguinal hernia:

The preferred method is **open repair** or **laparoscopic repair** with mesh placement to reduce the risk of recurrence.

Laparoscopic techniques (e.g., TEP – totally extraperitoneal repair) are used more commonly in **bilateral** or **recurrent** hernias.

Femoral hernia:

Surgical repair is recommended even for **asymptomatic** femoral hernias due to the **high risk of strangulation**.

Umbilical hernia:

Small, **asymptomatic umbilical hernias** in children may resolve spontaneously, but larger hernias in adults generally require **surgical repair**.

Emergency surgery:

Required for **incarcerated** or **strangulated hernias**, which present with **irreducible hernias**, severe pain, nausea, vomiting, and possible **bowel obstruction**.

Surgery involves hernia repair and assessment for **bowel ischaemia**, with resection if necessary.

Hiatal hernia:

Symptomatic cases may require **laparoscopic fundoplication** to prevent reflux and correct the herniation.

7. Common Contraindications and Second-Line Therapy

Contraindications:

Surgery may be contraindicated in patients with severe comorbidities, especially those with minimal symptoms. In such cases, **watchful waiting** or **non-surgical management** is preferred.

Second-Line Therapy:

Truss or hernia belt:

Sometimes used for patients unsuitable for surgery. However, this provides only temporary relief and does not treat the hernia.

Endoscopic repair:

For **hiatal hernia** that is symptomatic despite conservative management (e.g., acid suppression therapy).

8. Routine Monitoring and Follow-Up

For patients undergoing **watchful waiting**, regular follow-up is needed to monitor for changes in symptoms or complications.

Post-surgical follow-up is essential to check for **wound infection**, **hernia recurrence**, and resolution of symptoms.

Hiatal hernia patients may require regular endoscopic surveillance if symptomatic or at risk of complications like **Barrett's oesophagus**.

9. Complications of Hernias

Incarceration:

The hernia becomes **irreducible** and may lead to **bowel obstruction**.

Strangulation:

Cut-off blood supply to the herniated tissue, leading to ischaemia and necrosis. This is a surgical emergency.

Bowel obstruction:

Presents with **nausea, vomiting, and abdominal distension**, particularly in cases of **strangulated hernias**.

Recurrence:

Can occur following hernia repair, especially if mesh is not used or in the presence of predisposing factors such as **chronic cough** or **constipation**.

Summary of Key Points for Hernias

Hernias are the protrusion of tissue or organs through weakened areas of the abdominal wall, with the most common types being **inguinal**, **femoral**, **umbilical**, and **hiatal**.

First-line treatment is **surgical repair**, especially for **symptomatic**, **femoral**, or **complicated hernias**. **Conservative management** may be appropriate for asymptomatic cases.

Complications include **incarceration**, **strangulation**, and **bowel obstruction**, all of which require **emergency surgery**.

Routine follow-up is essential post-surgery to monitor for complications like **recurrence** or **wound infection**.

218. Abdominal Trauma

1. Detailed Definition of Abdominal Trauma

Abdominal trauma refers to injury to the **abdomen** due to **blunt** or **penetrating forces**. It can affect various **organs** within the **abdominal cavity** and **retroperitoneal space**, including the liver, spleen, kidneys, intestines, and major blood vessels. Abdominal trauma is typically divided into two main types:

Blunt abdominal trauma: Most commonly caused by **motor vehicle accidents**, falls, or assaults. It may result in injuries like organ lacerations, contusions, or ruptures without breaking the skin.

Penetrating abdominal trauma: Caused by **gunshot wounds**, **stab injuries**, or other objects that pierce the abdominal wall and may cause direct injury to internal organs.

2. Common Presenting Complaints and Symptoms

Pain:

Abdominal pain is often diffuse in blunt trauma or localised in penetrating injuries.

Bruising or distension:

Ecchymosis may indicate **internal bleeding**. **Abdominal distension** can be caused by free air or fluid within the abdominal cavity.

Guarding and rigidity:

In cases of **peritonitis**, the patient may display guarding (tensing of abdominal muscles) and a rigid abdomen, especially if bowel perforation has occurred.

Shock:

Signs of **hypovolemic shock** (e.g., hypotension, tachycardia, cold clammy skin) due to internal bleeding, especially from solid organ injuries like the spleen or liver.

Haematemesis or rectal bleeding:

May indicate **gastrointestinal injury**.

Rebound tenderness:

Indicates **peritonitis**, suggesting a perforated viscus or severe intra-abdominal pathology.

3. First-Line Investigations**a) Clinical Examination:****Primary survey (ABCDE approach):**

In any trauma case, follow the **ATLS (Advanced Trauma Life Support)** protocol with a focus on **airway, breathing, circulation**, and rapid identification of life-threatening injuries.

Secondary survey:

Detailed abdominal examination: Inspect for bruising, swelling, penetrating wounds, and assess for tenderness, guarding, and rigidity.

Focused Assessment with Sonography for Trauma (FAST):

A bedside **ultrasound scan** used to detect **free fluid** (usually blood) in the peritoneal, pleural, or pericardial spaces. It's especially useful in detecting haemoperitoneum in blunt trauma.

b) Imaging:**CT scan (contrast-enhanced):**

Gold standard imaging for evaluating **blunt abdominal trauma**. It can detect injuries to the solid organs (e.g., liver, spleen, kidneys) and hollow organs (e.g., bowel perforations), as well as retroperitoneal injuries.

X-ray:

May be useful to detect **free air** under the diaphragm (suggestive of bowel perforation) or fractures of the pelvis and ribs.

c) Blood Tests:**Full blood count (FBC):**

To check for **anaemia** or **haemorrhage**.

Serum lactate:

Elevated in cases of **hypoperfusion** and may indicate **tissue ischaemia** or **shock**.

Arterial blood gases (ABG):

Used to assess for **acidosis** (often present in shock) and oxygenation status.

Coagulation profile:

To evaluate clotting status, especially in cases where massive transfusion is required.

d) Diagnostic Peritoneal Lavage (DPL):

An older technique, but still used in unstable patients without access to CT. A catheter is inserted into the peritoneal cavity, and fluid is introduced. If blood or enteric contents return, it suggests significant intra-abdominal injury.

4. Explanation of Investigations

FAST scan: A rapid ultrasound used in trauma to identify free fluid (often blood) in the abdominal cavity, typically used at the bedside in the emergency department.

CT scan: The most definitive diagnostic tool for abdominal trauma, providing detailed information about both solid and hollow organ injuries.

5. Diagnosis Criteria for Abdominal Trauma

The diagnosis is made based on:

History of trauma (blunt or penetrating).

Physical examination findings (e.g., pain, rigidity, shock).

Imaging (e.g., FAST scan or CT scan) confirming the presence of injuries such as solid organ lacerations, hollow organ perforations, or free intra-abdominal fluid (blood).

6. First-Line Therapy According to Guidelines

a) Non-operative Management (NOM):

Blunt abdominal trauma with solid organ injury:

Non-operative management (NOM) is recommended for **stable patients** with injuries to the liver or spleen without evidence of haemodynamic instability or peritonitis.

This involves close monitoring in a **high dependency unit (HDU)** or **intensive care unit (ICU)** with serial **haemoglobin checks** and **imaging** to monitor for ongoing bleeding.

b) Operative Management:

Emergency laparotomy:

Indicated for patients with **penetrating abdominal trauma**, **haemodynamic instability**, or signs of **peritonitis**.

Exploratory laparotomy is performed to identify and repair damaged organs (e.g., bowel, liver, spleen) and control bleeding.

Damage control surgery:

Aimed at controlling life-threatening bleeding, contamination (from bowel perforation), and achieving temporary abdominal closure before full definitive repair at a later stage.

Embolisation:

For patients with **solid organ injuries** (e.g., liver or spleen) who are stable but have active bleeding on imaging. **Interventional radiology** can perform embolisation to stop the bleeding without the need for surgery.

7. Common Contraindications and Second-Line Therapy**Contraindications:**

Non-operative management is contraindicated in patients with **haemodynamic instability**, signs of **peritonitis**, or **hollow viscus injuries** (e.g., bowel perforation).

Second-Line Therapy:

Interventional radiology: Embolisation of bleeding vessels in stable patients with solid organ injuries to avoid surgery.

Re-laparotomy: If bleeding continues or the patient deteriorates after initial surgery.

8. Routine Monitoring and Follow-Up

Close monitoring in a **high-dependency** or **intensive care unit** for patients who are treated conservatively for solid organ injuries.

Serial haemoglobin levels and **repeat imaging** (CT or ultrasound) to assess for ongoing bleeding.

Post-operative care involves monitoring for complications such as **infections**, **bowel obstruction**, or **organ dysfunction**.

9. Complications of Abdominal Trauma**Haemorrhagic shock:**

Severe blood loss leading to **hypotension**, **tachycardia**, and potential multi-organ failure.

Peritonitis:

Caused by **bowel perforation**, leading to infection of the peritoneum.

Intra-abdominal abscess:

Localised infection within the abdominal cavity due to bowel perforation or trauma to solid organs.

Ischaemia:

Bowel ischaemia may occur due to reduced blood flow, especially in the case of bowel entrapment or strangulation.

Organ failure:

Trauma to vital organs like the **liver**, **spleen**, or **kidneys** can result in acute organ failure.

Summary of Key Points for Abdominal Trauma

Abdominal trauma can be blunt or penetrating, with common causes including **motor vehicle accidents**, **falls**, and **stab injuries**.

First-line investigations include the **FAST scan** for rapid detection of intra-abdominal bleeding, and **CT scanning** for detailed assessment of organ injuries.

Non-operative management is suitable for **stable** patients with **solid organ injuries**, while **emergency laparotomy** is indicated in unstable patients or those with peritonitis.

Complications include **haemorrhagic shock**, **peritonitis**, **intra-abdominal abscess**, and **organ failure**, all of which require immediate attention.

Haematology

219. Acquired Factors for Venous Thromboembolism (VTE)

1. Detailed Definition of Venous Thromboembolism (VTE)

Venous thromboembolism (VTE) refers to the formation of a **blood clot (thrombus)** in the venous system, typically in the deep veins of the legs, thighs, or pelvis (deep vein thrombosis, DVT). This clot can dislodge and travel to the lungs, resulting in a **pulmonary embolism (PE)**, a potentially life-threatening condition. VTE is a significant cause of morbidity and mortality, particularly in hospitalised or post-operative patients. Acquired factors, particularly during **surgery**, **hospitalisation**, and other clinical scenarios, contribute significantly to the development of VTE.

2. Acquired Risk Factors for VTE

Acquired risk factors for VTE are conditions or circumstances that increase the risk of blood clot formation. These factors can either be transient (temporary) or persistent and often involve **immobilisation**, **inflammation**, or **vascular damage**. Below are the major acquired risk factors for VTE:

A) Surgery and Trauma:

Major Surgery: Prolonged surgery (>30 minutes) under general or regional anaesthesia, particularly **orthopaedic**, **pelvic**, **abdominal**, or **cancer-related surgeries**, increases the risk of VTE due to immobility and vascular injury.

Trauma: Severe trauma (e.g., fractures, especially of the pelvis or femur) leads to endothelial injury and immobility, significantly increasing the risk of VTE.

B) Hospitalisation and Immobilisation:

Hospitalisation: Prolonged hospital stays, particularly in patients with acute illnesses or those in intensive care, are a common risk factor due to immobility and systemic inflammation.

Bed Rest or Immobilisation: Extended periods of immobility (e.g., bed rest or cast immobilisation for fractures) slow venous blood flow, promoting clot formation.

C) Cancer and Chemotherapy:

Cancer: Patients with **malignancies**, especially **pancreatic, lung, stomach, ovarian, and brain cancers**, have a higher risk of VTE due to tumour-induced hypercoagulability.

Chemotherapy: Certain chemotherapy agents and **cancer-related treatments** (e.g., hormone therapy or anti-angiogenic therapy) can increase the risk of VTE by inducing endothelial damage and altering blood clotting factors.

D) Hormonal Factors:

Hormone Replacement Therapy (HRT): **Oestrogen-containing HRT** increases the risk of VTE by promoting hypercoagulability.

Oral Contraceptives: Combined **oestrogen-progestin contraceptive pills** elevate the risk of VTE, particularly in women with additional risk factors (e.g., smoking, obesity, or inherited thrombophilias).

Pregnancy and the Postpartum Period: Pregnancy causes hypercoagulability, venous stasis, and endothelial changes, especially in the third trimester and the postpartum period, increasing the risk of DVT and PE.

E) Obesity:

Obesity: Being overweight ($\text{BMI} \geq 30 \text{ kg/m}^2$) increases the risk of VTE, particularly in combination with other risk factors like immobility or surgery. Obesity is associated with chronic low-grade inflammation, which can promote clot formation.

F) Acute Medical Illnesses:

Heart Failure: Chronic heart failure leads to venous stasis and increased risk of VTE, particularly in patients with limited mobility.

Acute Infections: Sepsis or severe infections can activate the coagulation cascade, increasing the risk of clot formation.

Inflammatory Disorders: Conditions such as **inflammatory bowel disease (IBD)** or **autoimmune diseases** can increase the risk of VTE due to chronic inflammation and endothelial activation.

G) Venous Catheters and Devices:

Central Venous Catheters: **Peripherally inserted central catheters (PICC lines)** or central venous catheters (CVCs) can damage the vessel wall and increase the risk of thrombosis at the insertion site.

Pacemakers or Other Cardiac Devices: Placement of devices can lead to endothelial trauma and subsequent thrombosis.

H) Lifestyle and Behavioural Factors:

Prolonged Travel: Long-haul flights or extended periods of sitting during travel (>4 hours) can lead to venous stasis, particularly in the legs, contributing to the risk of DVT.

Smoking: Smoking causes endothelial damage and promotes a prothrombotic state, increasing the likelihood of VTE.

I) Age:

Older Age: The risk of VTE increases with age due to reduced mobility, vascular changes, and comorbidities that contribute to venous stasis and hypercoagulability.

J) Previous VTE:

History of VTE: Patients with a previous episode of DVT or PE are at higher risk of recurrent events, particularly in the presence of ongoing risk factors (e.g., malignancy, immobility).

3. Pathophysiology of Acquired VTE Risk Factors

The **Virchow's Triad**—consisting of **venous stasis**, **endothelial injury**, and **hypercoagulability**—describes the three main processes that lead to thrombosis. Acquired factors contribute to these processes as follows:

Venous Stasis: Prolonged immobility from hospitalisation, bed rest, or long-distance travel slows blood flow, promoting clot formation.

Endothelial Injury: Trauma, surgery, and the presence of indwelling catheters disrupt the vascular endothelium, creating a prothrombotic surface.

Hypercoagulability: Cancer, pregnancy, hormonal therapies, and systemic inflammation (from infection or chronic diseases) shift the coagulation balance toward clot formation.

4. First-Line Investigations for VTE Risk Assessment in Pre-Operative Patients

A) D-dimer Testing:

What it measures: Measures fibrin degradation products in the blood, indicating clot formation and breakdown.

Purpose: Helps rule out VTE if negative, but elevated levels are non-specific and can be due to other conditions (e.g., inflammation, infection).

Findings: Elevated in acute VTE, but further imaging is needed to confirm the diagnosis.

B) Venous Doppler Ultrasound:

What it examines: Ultrasound of the legs to assess for the presence of DVT in the deep veins.

Purpose: Non-invasive and first-line imaging to confirm the presence of a thrombus in the leg veins.

Findings: Visualizes thrombus formation in the affected vein.

C) Computed Tomography Pulmonary Angiography (CTPA):

What it examines: Imaging of the pulmonary arteries.

Purpose: The gold standard for diagnosing **pulmonary embolism (PE)**.

Findings: Visualizes clots in the pulmonary vasculature.

D) Coagulation Studies:

What it examines: Tests such as **prothrombin time (PT)**, **activated partial thromboplastin time (aPTT)**, and **fibrinogen** levels.

Purpose: Assesses the overall functioning of the coagulation system, especially in patients with an acquired hypercoagulable state (e.g., cancer, liver disease).

5. First-Line Prophylaxis for VTE According to Guidelines

NICE guidelines recommend **pharmacological** and **mechanical prophylaxis** based on patient risk factors.

A) Pharmacological Prophylaxis:

Low-Molecular-Weight Heparin (LMWH):

Example: Enoxaparin 40 mg subcutaneously once daily.

Mechanism: Inhibits factor Xa and thrombin, preventing clot formation.

Use: First-line for most hospitalised and post-operative patients at risk for VTE.

Direct Oral Anticoagulants (DOACs):

Example: Rivaroxaban 10 mg orally once daily.

Mechanism: Inhibits factor Xa.

Use: Common in certain post-operative settings, especially in orthopaedic surgery.

Unfractionated Heparin (UFH):

Example: Heparin 5,000 units subcutaneously every 8-12 hours.

Use: In patients with high bleeding risk or renal impairment where LMWH is contraindicated.

B) Mechanical Prophylaxis:

Intermittent Pneumatic Compression Devices:

Mechanism: Sequential compression of the legs to improve venous return.

Use: For patients with a high bleeding risk or in combination with pharmacological prophylaxis.

Graduated Compression Stockings:

Mechanism: Improve venous return and prevent stasis.

Use: In patients where anticoagulation is contraindicated.

6. Contraindications and Considerations in Prophylaxis

A) Contraindications to Pharmacological Prophylaxis:

Active Bleeding: Avoid anticoagulants in patients with active or high-risk bleeding.

Severe Renal Impairment: Adjust or avoid LMWH in patients with creatinine clearance <30 mL/min; consider UFH instead.

Recent Major Surgery or Trauma: Delayed initiation of anticoagulation may be needed.

B) Considerations for Special Populations:

Pregnancy: LMWH is preferred over warfarin or DOACs due to safety profile in pregnancy.

Obesity: Higher doses of LMWH may be required for effective prophylaxis in obese patients.

7. Routine Monitoring and Follow-Up

A) Laboratory Monitoring:

Anti-Xa Levels: In patients on LMWH, especially those with renal impairment or obesity.

PT/aPTT: In patients on UFH for VTE prophylaxis.

B) Clinical Monitoring:

Signs of Bleeding: Monitor for signs of bleeding, including bruising, gastrointestinal bleeding, or intracranial hemorrhage.

VTE Symptoms: Regular assessment for symptoms of DVT (swelling, pain) and PE (shortness of breath, chest pain).

8. Complications of VTE in the Perioperative Period

A) Deep Vein Thrombosis (DVT):

Cause: Clot formation in the deep veins of the legs or pelvis.

Management: Anticoagulation and thrombolysis in severe cases.

B) Pulmonary Embolism (PE):

Cause: Migration of a thrombus from the deep veins to the lungs.

Management: Immediate anticoagulation, oxygen therapy, and thrombolysis in life-threatening cases.

C) Post-Thrombotic Syndrome:

Cause: Chronic venous insufficiency following DVT, leading to swelling and pain.

Management: Compression stockings and physical therapy.

Summary of Key Points for Acquired Factors of VTE

Acquired factors for VTE include **immobility**, **surgery**, **cancer**, **hormonal therapy**, and **acute illnesses**.

Risk factors such as **hospitalisation**, **obesity**, and **pregnancy** increase the likelihood of clot formation due to **venous stasis**, **endothelial injury**, and **hypercoagulability**.

First-line prophylaxis involves **LMWH** or **DOACs** for pharmacological prevention, with **mechanical devices** like compression stockings or pneumatic devices in patients at high risk for bleeding.

Monitoring focuses on detecting signs of **bleeding** and **VTE symptoms**, with attention to balancing the risk of thrombosis and bleeding in pre-operative care.

220. Anaemia of Chronic Disease (ACD)

1. Detailed Definition of Anaemia of Chronic Disease (ACD)

Anaemia of Chronic Disease (ACD), also known as **anaemia of inflammation**, is a type of anaemia that occurs in association with **chronic infections**, **chronic inflammatory conditions**, and **malignancies**. It is characterised by altered **iron metabolism**, **impaired erythropoiesis** (red blood cell production), and reduced response to **erythropoietin** (a hormone stimulating red blood cell production).

ACD results from the immune system's response to chronic disease, which involves the release of **cytokines** such as **interleukin-6 (IL-6)**. These cytokines promote the sequestration of iron in macrophages and the liver, making it less available for red blood cell production, while also inhibiting erythropoiesis and reducing the lifespan of red blood cells.

This type of anaemia is usually **mild to moderate** in severity, with haemoglobin levels typically ranging from **85-115 g/L**.

2. Common Presenting Complaints and Symptoms of Anaemia of Chronic Disease

ACD is often associated with **chronic conditions**, so its symptoms may overlap with those of the underlying disease. Symptoms of ACD may include:

A) General Symptoms of Anaemia:

Fatigue: Common and persistent tiredness.

Weakness: General physical weakness and reduced stamina.

Shortness of Breath: Particularly on exertion.

Pallor: Pale skin or mucous membranes.

Dizziness or Lightheadedness: Especially in more severe cases.

Tachycardia: Increased heart rate, which may be compensatory for low haemoglobin.

B) Symptoms Related to the Underlying Chronic Disease:

Chronic Infections: Symptoms like fever, night sweats, and weight loss in cases of tuberculosis or HIV.

Chronic Inflammatory Conditions: Joint pain, swelling, and stiffness in conditions like rheumatoid arthritis.

Chronic Kidney Disease (CKD): Fatigue, reduced urine output, and oedema.

Cancer: Weight loss, night sweats, and fatigue related to malignancies.

3. First-Line Investigations for Anaemia of Chronic Disease

The diagnosis of ACD involves blood tests to assess **haemoglobin levels, iron metabolism, and inflammatory markers**. Investigations include:

A) Full Blood Count (FBC):

Purpose: To evaluate the severity of anaemia and its characteristics.

Findings:

Mild to Moderate Anaemia: Haemoglobin levels usually between 85-115 g/L.

Normocytic or Microcytic Anaemia: Mean corpuscular volume (MCV) is typically normal (80-100 fL) or slightly low (<80 fL).

Normal to Reduced Reticulocyte Count: Reflects reduced red blood cell production.

B) Serum Ferritin:

Purpose: To assess iron stores. Ferritin is an acute-phase reactant, so it rises in response to inflammation.

Findings:

Normal or Elevated Ferritin: Ferritin is often elevated (>100 ng/mL) in ACD due to inflammation, helping to differentiate ACD from iron deficiency anaemia (where ferritin is low).

C) Serum Iron, Total Iron-Binding Capacity (TIBC), and Transferrin Saturation:

Purpose: To evaluate iron metabolism.

Findings:

Low Serum Iron: Iron levels are reduced due to iron sequestration.

Low TIBC: TIBC is reduced or normal in ACD (unlike iron deficiency, where it is elevated).

Low Transferrin Saturation: Indicates insufficient iron available for erythropoiesis.

D) Inflammatory Markers:

C-Reactive Protein (CRP) and Erythrocyte Sedimentation Rate (ESR):

Purpose: To assess for inflammation contributing to ACD.

Findings: Elevated CRP and ESR, indicating chronic inflammation.

Hepcidin Levels (if available):

Purpose: To assess for functional iron deficiency.

Findings: Hepcidin, a hormone that regulates iron absorption and sequestration, is elevated in ACD, contributing to low iron availability.

4. Diagnostic Criteria for Anaemia of Chronic Disease (ACD)

The diagnosis of ACD is based on a combination of clinical findings, laboratory results, and the presence of a chronic underlying condition:

Chronic Disease: Diagnosis of a chronic infection, inflammatory disorder (e.g., rheumatoid arthritis, inflammatory bowel disease), or malignancy.

Anaemia: Haemoglobin typically between 85-115 g/L.

Iron Studies:

Low Serum Iron and **low or normal TIBC**.

Normal or elevated serum ferritin (>100 ng/mL).

Low transferrin saturation (<20%).

Inflammatory Markers: Raised CRP and ESR.

The presence of chronic disease, inflammatory markers, and normal or elevated ferritin helps differentiate ACD from iron-deficiency anaemia.

5. First-Line Management According to NICE Guidelines

The treatment of ACD focuses on managing the **underlying chronic condition** and improving anaemia where necessary. Specific treatments for ACD include:

A) Treatment of the Underlying Condition:

Anti-inflammatory and Immunosuppressive Therapy:

Rheumatoid Arthritis: Disease-modifying anti-rheumatic drugs (DMARDs) like **methotrexate** or **biological agents** such as **TNF inhibitors** (e.g., infliximab).

Chronic Infections: Appropriate antibiotics or antivirals for infections like tuberculosis or HIV.

Cancer Therapy:

Chemotherapy, Radiotherapy, or Surgery: Treatment tailored to the specific cancer, aiming to reduce tumour burden and inflammation.

B) Management of Anaemia:

Erythropoiesis-Stimulating Agents (ESAs):

Epoetin Alfa or Darbepoetin Alfa:

Indication: Used particularly in **chronic kidney disease** and certain cancers to stimulate red blood cell production.

Dose: Epoetin alfa is typically given at 50-100 units/kg subcutaneously 1-3 times weekly, adjusted based on the response.

Outcome: Increases haemoglobin levels and reduces the need for blood transfusions.

Iron Therapy (if iron deficiency is present):

Oral or Intravenous Iron:

Indication: Only if there is a co-existing iron deficiency (e.g., chronic blood loss) along with ACD.

Outcome: Corrects iron deficiency and improves erythropoiesis if iron stores are depleted.

Blood Transfusions:

Indication: Reserved for severe anaemia (haemoglobin <70-80 g/L) where immediate correction is needed, or if the patient is symptomatic and unresponsive to other treatments.

Outcome: Rapid increase in haemoglobin, though only a temporary solution.

C) Other Supportive Measures:

Nutritional Support: Correct any concurrent deficiencies (e.g., vitamin B12 or folate).

Management of Comorbidities: Control of conditions such as chronic kidney disease or heart failure that may exacerbate anaemia.

6. Routine Monitoring and Follow-Up

A) Haemoglobin Levels:

Frequency: Regular monitoring every **2-4 weeks** to assess the response to treatment, especially if using **erythropoiesis-stimulating agents (ESAs)**.

Target: Maintain haemoglobin levels at 100-120 g/L to avoid overcorrection.

B) Iron Studies:

Frequency: Periodic monitoring of **ferritin** and **transferrin saturation** to ensure adequate iron stores, particularly in patients receiving iron supplementation.

C) Inflammatory Markers:

CRP and **ESR** levels should be monitored to assess the activity of the underlying chronic condition, especially in inflammatory diseases like rheumatoid arthritis or inflammatory bowel disease.

7. Complications of Anaemia of Chronic Disease

A) Increased Morbidity:

Anaemia can exacerbate **fatigue**, **reduced exercise tolerance**, and **poor quality of life**, particularly in patients with chronic diseases.

B) Cardiovascular Complications:

Chronic anaemia increases the workload on the heart, potentially leading to **heart failure**, **left ventricular hypertrophy**, and worsening outcomes in patients with pre-existing heart disease.

C) Transfusion-Related Complications:

Iron Overload: Repeated blood transfusions may lead to excess iron accumulation (secondary haemochromatosis).

Transfusion Reactions: Alloimmunisation or acute transfusion reactions may occur.

Summary of Key Points for Anaemia of Chronic Disease (ACD)

ACD is a common anaemia associated with chronic inflammatory, infectious, or malignant diseases, typically presenting as mild-to-moderate **normocytic** or **microcytic** anaemia.

Diagnosis involves identifying a chronic underlying condition, detecting low serum iron, low transferrin saturation, and elevated inflammatory markers, with normal or raised ferritin levels distinguishing ACD from iron-deficiency anaemia.

First-line treatment focuses on managing the **underlying chronic disease** and using **erythropoiesis-stimulating agents (ESAs)** in cases of significant anaemia.

Monitoring includes regular checks of haemoglobin, iron levels, and inflammatory markers, with the aim of maintaining stable haemoglobin levels and controlling the underlying disease.

221. Anaemia of Coagulation and Its Disorders

1. Detailed Definition of Anaemia of Coagulation and Its Disorders

Anaemia associated with **coagulation disorders** occurs when blood loss, either acute or chronic, leads to a significant reduction in haemoglobin levels, often due to an underlying defect in the blood's ability to clot. **Coagulation disorders** are conditions where the body's normal clotting process is impaired, resulting in excessive bleeding, which can lead to **iron deficiency anaemia** or other forms of anaemia.

Common coagulation disorders that can result in anaemia include:

Haemophilia (A and B): Genetic disorders resulting in deficient or absent clotting factors VIII or IX.

Von Willebrand Disease: A genetic disorder that affects the von Willebrand factor, important for platelet function and clotting.

Disseminated Intravascular Coagulation (DIC): A severe, acquired condition in which widespread clotting occurs, depleting clotting factors and platelets, leading to bleeding and anaemia.

Liver Disease: Impaired production of clotting factors in the liver can lead to bleeding tendencies.

Thrombocytopenia: Low platelet counts, which result in reduced ability to form clots and cause bleeding.

2. Common Presenting Complaints and Symptoms Related to Anaemia in Coagulation Disorders

Patients with anaemia due to coagulation disorders may present with symptoms related to both the **anaemia** itself and **bleeding tendencies**. These include:

A) Symptoms of Anaemia:

Fatigue: Generalised tiredness and reduced energy levels.

Pallor: Pale skin and mucous membranes.

Shortness of Breath: Dyspnoea on exertion due to reduced oxygen-carrying capacity.

Tachycardia: Increased heart rate as a compensatory mechanism for low haemoglobin levels.

Dizziness or Lightheadedness: Particularly after acute blood loss or in cases of severe anaemia.

B) Symptoms of Coagulation Disorders:

Easy Bruising: Patients may notice bruises after minor trauma or without any injury.

Prolonged Bleeding: Extended bleeding from minor cuts, dental procedures, or after surgery.

Spontaneous Bleeding: Unexplained nosebleeds, bleeding gums, or gastrointestinal bleeding.

Heavy Menstrual Bleeding: In women, menorrhagia is a common manifestation of a bleeding disorder.

Hemarthrosis (in haemophilia): Bleeding into joints, causing pain, swelling, and limited mobility.

Petechiae or Purpura: Small, pinpoint red or purple spots on the skin, indicative of bleeding under the skin (common in thrombocytopenia).

3. First-Line Investigations for Anaemia and Coagulation Disorders

When investigating anaemia in the context of coagulation disorders, it is important to assess both the severity of the anaemia and the underlying clotting abnormality. Key investigations include:

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels, red blood cell indices, and platelet counts.

Findings:

Low Haemoglobin: Indicates anaemia, which may be normocytic or microcytic if related to chronic blood loss (e.g., iron deficiency).

Thrombocytopenia: If present, suggests a bleeding tendency due to low platelets.

B) Coagulation Profile:

Prothrombin Time (PT):

Purpose: Assesses the extrinsic pathway of coagulation, including factors I (fibrinogen), II (prothrombin), V, VII, and X.

Findings: Prolonged PT may indicate deficiencies in clotting factors, commonly seen in liver disease or vitamin K deficiency.

Activated Partial Thromboplastin Time (aPTT):

Purpose: Evaluates the intrinsic pathway, assessing factors I, II, V, VIII, IX, X, XI, and XII.

Findings: Prolonged aPTT is seen in **haemophilia** and **von Willebrand disease**.

Fibrinogen Levels:

Purpose: Fibrinogen is a critical clotting factor.

Findings: Low levels suggest severe consumption in conditions like **disseminated intravascular coagulation (DIC)**.

Platelet Count:

Purpose: Assesses the number of platelets.

Findings: **Thrombocytopenia** indicates an increased bleeding risk.

C) Specific Coagulation Factor Assays:

Purpose: To measure levels of individual clotting factors, such as **factor VIII** in haemophilia A or **factor IX** in haemophilia B.

Findings: Deficiencies in specific factors confirm the diagnosis of hereditary bleeding disorders.

D) Iron Studies:

Purpose: To assess for iron deficiency due to chronic blood loss.

Findings:

Low Ferritin: Suggests iron deficiency anaemia.

Low Serum Iron and Transferrin Saturation: Consistent with iron deficiency anaemia secondary to chronic bleeding.

E) Liver Function Tests:

Purpose: To evaluate liver function, which is crucial for the synthesis of clotting factors.

Findings: Abnormalities in liver enzymes may indicate liver disease, which can impair clotting factor production.

F) Von Willebrand Factor Antigen and Activity Tests:

Purpose: To diagnose **von Willebrand disease**, which affects both platelet function and the coagulation cascade.

Findings: Reduced von Willebrand factor levels and activity confirm the diagnosis.

4. Explanation of Investigations

a) Full Blood Count (FBC):

Procedure: A blood sample is tested for haemoglobin, red blood cell indices, and platelet levels.

Interpretation: Anaemia and thrombocytopenia are often seen in bleeding disorders; the anaemia may be normocytic (acute blood loss) or microcytic (chronic blood loss leading to iron deficiency).

b) Coagulation Profile (PT, aPTT, Fibrinogen):

Procedure: A blood sample is analysed to assess how long it takes for blood to clot.

Interpretation: Prolongation of PT or aPTT indicates defects in specific parts of the coagulation cascade, which helps guide the diagnosis of coagulation disorders like haemophilia or DIC.

5. Diagnostic Criteria for Anaemia in Coagulation Disorders

Diagnosis is based on:

Anaemia: Identified through FBC, usually normocytic or microcytic, depending on the duration and extent of blood loss.

Coagulation Disorder: Confirmed by prolonged PT, aPTT, or specific factor deficiencies (e.g., factor VIII in haemophilia A or von Willebrand factor activity in von Willebrand disease).

Iron Deficiency: Indicated by low ferritin and serum iron levels, particularly in chronic blood loss.

6. First-Line Therapy According to Guidelines

Management of anaemia in coagulation disorders focuses on controlling bleeding, correcting the coagulation disorder, and treating the anaemia itself.

A) Management of Coagulation Disorders:

Factor Replacement Therapy:

Haemophilia A (Factor VIII Deficiency):

Treatment: **Factor VIII concentrate** is administered intravenously to replace the missing factor.

Dose: Dosed based on the severity of bleeding and weight (e.g., 20-50 units/kg for moderate bleeding episodes).

Haemophilia B (Factor IX Deficiency):

Treatment: **Factor IX concentrate.**

Desmopressin (DDAVP):

Use: For **mild haemophilia A** and **von Willebrand disease**.

Mechanism: Stimulates the release of stored **von Willebrand factor** and **factor VIII**.

Outcome: Reduces bleeding tendencies.

Fresh Frozen Plasma (FFP):

Use: In cases of **disseminated intravascular coagulation (DIC)** or severe **liver disease** with clotting factor deficiencies.

Mechanism: Replaces multiple clotting factors.

Platelet Transfusion:

Use: For patients with **severe thrombocytopenia** or platelet dysfunction causing bleeding.

Outcome: Increases platelet count and reduces bleeding risk.

B) Management of Anaemia:**Iron Therapy:****Oral or Intravenous Iron:**

Indication: For iron deficiency anaemia secondary to chronic blood loss (e.g., gastrointestinal bleeding).

Dose: Oral iron (e.g., ferrous sulfate 200 mg three times daily) or intravenous iron for patients who cannot tolerate oral formulations.

Blood Transfusions:

Indication: For severe anaemia (haemoglobin <70-80 g/L) with symptomatic patients or those with acute bleeding.

Outcome: Immediate correction of anaemia.

7. Common Contraindications and Second-Line Therapy**A) Contraindications:**

Desmopressin (DDAVP): Use with caution in patients with cardiovascular disease, as it can cause fluid retention and hyponatraemia.

Factor Replacement: Careful monitoring for **inhibitor development** (antibodies against factor VIII or IX) in haemophilia patients.

B) Second-Line Therapy:

Recombinant Activated Factor VII: Used in haemophilia patients with inhibitors.

Antifibrinolytics: Such as **tranexamic acid** for controlling minor bleeding episodes, especially in the mouth or nose.

8. Routine Monitoring and Follow-Up

A) Haemoglobin Levels:

Frequency: Regular monitoring to ensure the anaemia is improving, especially after iron therapy or transfusions.

B) Coagulation Tests (PT, aPTT):

Frequency: Monitor coagulation status in patients receiving factor replacement or plasma products.

Target: Normalisation of clotting times and resolution of bleeding.

C) Iron Studies:

Frequency: Repeat iron studies every **1-3 months** in patients receiving iron therapy to ensure adequate replenishment of iron stores.

9. Complications of Anaemia and Coagulation Disorders

A) Haemorrhage:

Cause: Life-threatening bleeding in patients with severe coagulation disorders (e.g., intracranial haemorrhage in haemophilia).

Management: Urgent factor replacement or transfusion.

B) Iron Overload:

Cause: Excessive iron intake from multiple blood transfusions.

Management: **Iron chelation therapy** (e.g., deferoxamine) to prevent organ damage.

C) Thromboembolic Events:

Cause: Over-replacement of clotting factors can paradoxically increase the risk of clot formation.

Management: Careful dosing and monitoring of replacement therapies.

Summary of Key Points for Anaemia of Coagulation and Its Disorders

Anaemia in coagulation disorders results from chronic or acute bleeding due to impaired clot formation, commonly seen in conditions like **haemophilia**, **von Willebrand disease**, and **disseminated intravascular coagulation (DIC)**.

Diagnosis involves assessing haemoglobin levels and clotting times (PT, aPTT), along with specific factor assays to confirm the underlying disorder.

First-line treatment includes **factor replacement therapy** (e.g., factor VIII or IX), **iron supplementation** for chronic blood loss, and **blood transfusions** in severe anaemia.

Monitoring focuses on haemoglobin levels, iron stores, and coagulation parameters to guide therapy and prevent complications like haemorrhage or iron overload.

222. Management of an Anticoagulated Patient with Bleeding

1. Detailed Definition of Bleeding in Anticoagulated Patients

Bleeding in an **anticoagulated patient** refers to hemorrhage or excessive bleeding that occurs due to the impaired clotting function caused by anticoagulant therapy. **Anticoagulants** such as **warfarin**, **direct oral anticoagulants (DOACs)** (e.g., rivaroxaban, apixaban, dabigatran), and **heparin** are commonly used to prevent thromboembolic events but increase the risk of bleeding.

Bleeding in these patients can be classified into:

Minor Bleeding: Easily controlled bleeding (e.g., epistaxis, minor bruising).

Major Bleeding: Life-threatening or serious bleeding requiring immediate intervention (e.g., gastrointestinal bleeding, intracranial hemorrhage, hematuria).

The challenge in managing anticoagulated patients with bleeding involves **reversing anticoagulation** when necessary while balancing the risk of thromboembolism.

2. Common Presenting Complaints and Symptoms Related to Bleeding in Anticoagulated Patients

Patients on anticoagulant therapy may present with varying degrees of bleeding, from mild to life-threatening. Common symptoms include:

A) Minor Bleeding:

Epistaxis: Nosebleeds.

Gingival Bleeding: Bleeding from the gums.

Bruising: Excessive bruising after minor trauma (ecchymosis).

Prolonged Bleeding from Cuts: Increased bleeding from minor wounds or surgical sites.

B) Major Bleeding:

Gastrointestinal Bleeding:

Hematemesis: Vomiting blood.

Melena: Black, tarry stools indicating upper GI bleeding.

Hematochezia: Bright red blood in stools, suggesting lower GI bleeding.

Intracranial Hemorrhage:

Sudden Severe Headache: Possibly accompanied by vomiting or neurological deficits (e.g., weakness, confusion).

Loss of Consciousness: In severe cases.

Hematuria: Blood in the urine.

Hemoptysis: Coughing up blood.

Retroperitoneal Hemorrhage:

Flank Pain: Associated with large blood loss into the retroperitoneal space.

Perioperative or Postoperative Bleeding: Excessive or prolonged bleeding during or after surgery.

3. First-Line Investigations for Bleeding in an Anticoagulated Patient

When a patient on anticoagulants presents with bleeding, the first step is to assess the severity of bleeding, evaluate the anticoagulation status, and determine appropriate interventions. Key investigations include:

A) Full Blood Count (FBC):

Purpose: To assess the extent of blood loss and anaemia.

Findings:

Low Haemoglobin: Indicates significant blood loss.

Low Platelets: May suggest drug-induced thrombocytopenia (e.g., heparin-induced thrombocytopenia).

B) Coagulation Profile:

International Normalised Ratio (INR) (for patients on **warfarin**):

Purpose: To assess the level of anticoagulation.

Findings: An elevated INR (>3.0) suggests excessive anticoagulation and increased bleeding risk.

Activated Partial Thromboplastin Time (aPTT) (for patients on **heparin**):

Purpose: To measure the anticoagulant effect of heparin.

Findings: Prolonged aPTT indicates excessive anticoagulation with unfractionated heparin.

Anti-Xa Levels (for patients on **LMWH or DOACs**):

Purpose: To assess the anticoagulant effect of low-molecular-weight heparin (LMWH) or factor Xa inhibitors (e.g., rivaroxaban, apixaban).

Findings: High anti-Xa levels suggest an increased bleeding risk.

Thrombin Time (TT) (for patients on **dabigatran**):

Purpose: To evaluate the anticoagulant effect of dabigatran (a direct thrombin inhibitor).

Findings: Prolonged TT indicates excessive anticoagulation.

C) Renal and Liver Function Tests:

Purpose: To assess for underlying renal or hepatic impairment, which can prolong the effects of anticoagulants.

Findings:

Renal Impairment: May delay clearance of DOACs or LMWH, increasing the risk of bleeding.

Liver Impairment: Can impair clotting factor production, exacerbating bleeding risks.

D) Imaging Studies (if indicated for major bleeding):

CT Brain: To assess for **intracranial hemorrhage** in patients presenting with sudden headache, neurological deficits, or altered consciousness.

Endoscopy or Colonoscopy: To localise **gastrointestinal bleeding**.

CT Abdomen: To detect **retroperitoneal hemorrhage** or other internal bleeding.

4. Explanation of Investigations

a) Coagulation Profile (INR, aPTT, Anti-Xa):

Procedure: Blood samples are taken to assess how long it takes for blood to clot (INR and aPTT) or to measure direct anticoagulant activity (Anti-Xa for DOACs and LMWH).

Interpretation:

INR: A high INR (>3.0) indicates an increased bleeding risk in patients on warfarin.

aPTT: Prolonged in patients on heparin; used to monitor therapy.

Anti-Xa Levels: Elevated in patients on factor Xa inhibitors or LMWH, indicating increased anticoagulant activity.

5. Management of Bleeding in Anticoagulated Patients

Management depends on the severity of bleeding and the type of anticoagulant the patient is using. Treatment strategies include **stopping the anticoagulant**, administering **reversal agents**, and providing supportive care as needed.

A) General Measures for All Patients:

Stop Anticoagulant: Discontinue the anticoagulant immediately if significant bleeding is present.

Supportive Care:

Intravenous Fluids: To maintain blood pressure and organ perfusion in cases of significant blood loss.

Blood Transfusions: If haemoglobin levels are critically low or if there is active bleeding.

B) Specific Reversal Agents for Anticoagulants:

Warfarin (Vitamin K Antagonist):

Reversal Agent:

Vitamin K (phytonadione):

Dose: 5-10 mg IV for major bleeding.

Mechanism: Reverses warfarin's effect by promoting the synthesis of clotting factors.

Prothrombin Complex Concentrate (PCC):

Dose: 25-50 units/kg IV, based on INR and bleeding severity.

Mechanism: Provides immediate replacement of clotting factors II, VII, IX, and X.

Fresh Frozen Plasma (FFP): Can be used if PCC is unavailable.

DOACs (Rivaroxaban, Apixaban - Factor Xa Inhibitors):

Reversal Agent:

Andexanet Alfa:

Mechanism: Binds to and neutralises factor Xa inhibitors.

Prothrombin Complex Concentrate (PCC): Alternative when andexanet alfa is not available.

Dabigatran (Direct Thrombin Inhibitor):

Reversal Agent:

Idarucizumab:

Dose: 5 g IV (given as two 2.5 g doses).

Mechanism: Binds to and neutralises dabigatran's anticoagulant effect.

Unfractionated Heparin:

Reversal Agent:

Protamine Sulfate:

Dose: 1 mg of protamine neutralises approximately 100 units of heparin.

Mechanism: Binds to heparin, forming an inactive complex.

Low Molecular Weight Heparin (LMWH) (e.g., enoxaparin):

Reversal Agent:

Protamine Sulfate: Partial reversal; 1 mg of protamine neutralises about 1 mg of enoxaparin (only effective for the last 8 hours of enoxaparin dose).

C) Management of Specific Bleeding Sites:**Intracranial Hemorrhage:**

Immediate reversal of anticoagulation (e.g., vitamin K, PCC, idarucizumab) and **neurosurgical consultation**.

Gastrointestinal Bleeding:

Endoscopy may be required for diagnosis and therapeutic intervention (e.g., clipping, cauterisation).

Reversal of anticoagulation if bleeding is severe.

Retroperitoneal Hemorrhage:

Supportive care with fluids and blood products; surgical intervention may be necessary for ongoing bleeding.

6. Common Contraindications and Considerations for Reversal**A) Contraindications:**

Idarucizumab: Use with caution in patients with hypersensitivity to the drug.

Protamine Sulfate: May cause allergic reactions or hypotension; use cautiously in patients with a history of fish allergies.

B) Considerations for Restarting Anticoagulation:

Assess the risk of **thromboembolism** vs the risk of rebleeding.

Anticoagulation may need to be restarted once bleeding is controlled, particularly in high-risk patients (e.g., those with atrial fibrillation, mechanical heart valves, or a history of venous thromboembolism).

Bridging with heparin may be necessary when restarting warfarin.

7. Routine Monitoring and Follow-Up**A) Monitoring Coagulation:**

INR: Monitor daily in patients on warfarin who have experienced bleeding, adjusting vitamin K or warfarin doses accordingly.

Anti-Xa Levels: If DOACs or LMWH were used, monitor anti-Xa levels if available after reversal.

B) Haemoglobin and Platelet Count:

Frequency: Monitor every 6-12 hours in cases of significant blood loss until stabilised.

Purpose: To assess the need for blood transfusions or further interventions.

8. Complications of Bleeding in Anticoagulated Patients

A) Thromboembolic Events:

Cause: Stopping anticoagulation or reversing it increases the risk of thromboembolism (e.g., stroke, deep vein thrombosis, pulmonary embolism).

Management: Carefully assess when it is safe to restart anticoagulation.

B) Hypovolemic Shock:

Cause: Massive blood loss leading to a drop in blood pressure and organ perfusion.

Management: Aggressive fluid resuscitation, blood transfusions, and surgical intervention if necessary.

C) Recurrent Bleeding:

Cause: Incomplete reversal or premature re-initiation of anticoagulation.

Management: Continuous monitoring and adjusting treatment based on bleeding control.

Summary of Key Points for Managing Bleeding in Anticoagulated Patients

Anticoagulated patients are at higher risk of bleeding, and management requires prompt assessment and appropriate reversal of anticoagulation.

Investigations include coagulation profiles (INR, aPTT, Anti-Xa levels), FBC, and imaging if major bleeding is suspected.

Reversal agents like **vitamin K** (for warfarin), **idarucizumab** (for dabigatran), and **andexanet alfa** (for factor Xa inhibitors) are crucial in managing bleeding.

Monitoring is essential for both the correction of bleeding and the prevention of thromboembolic complications once anticoagulation is reversed.

223. Blood Transfusion

1. Detailed Definition of Blood Transfusion

A **blood transfusion** is the administration of **whole blood** or **blood components**, such as **red blood cells (RBCs)**, **plasma**, **platelets**, or **cryoprecipitate**, into a patient's bloodstream to treat conditions like **severe anaemia**, **acute blood loss**, **coagulation disorders**, or **thrombocytopenia**. Blood transfusions can be **life-saving** in cases of trauma, surgery, or severe haemorrhage, and are essential in managing chronic conditions such as **haematological disorders** (e.g., thalassaemia, sickle cell disease) or **chemotherapy-induced anaemia**.

2. Common Indications for Blood Transfusion

The decision to transfuse blood is based on the **clinical condition** of the patient, **haemoglobin levels**, and other relevant blood parameters. Common indications include:

A) Red Blood Cell Transfusion:

Acute Blood Loss: Trauma, surgery, or gastrointestinal bleeding causing significant blood loss and haemodynamic instability.

Severe Anaemia:

Symptomatic Anaemia: Haemoglobin <70-80 g/L in symptomatic patients (e.g., dyspnoea, chest pain).

Chronic Anaemia: In conditions such as **chronic kidney disease (CKD)**, **sickle cell disease**, or **chemotherapy-induced anaemia**.

B) Platelet Transfusion:

Severe Thrombocytopenia:

Prophylactic Transfusion: Platelet count <10 x 10⁹/L in patients at risk of spontaneous bleeding (e.g., post-chemotherapy).

Active Bleeding: Platelet count <50 x 10⁹/L in patients with active bleeding or undergoing invasive procedures.

C) Fresh Frozen Plasma (FFP):

Coagulation Disorders:

Disseminated Intravascular Coagulation (DIC): To replace depleted clotting factors.

Massive Transfusion Protocol: During major trauma or surgery with ongoing bleeding and coagulopathy.

Liver Disease: In patients with coagulopathy due to liver dysfunction.

Warfarin Overdose: When urgent reversal of anticoagulation is needed, particularly in bleeding patients.

D) Cryoprecipitate:

Fibrinogen Deficiency:

Massive Transfusion Protocol: To replace fibrinogen, particularly in trauma or major haemorrhage.

Congenital Hypofibrinogenemia: In patients with inherited fibrinogen deficiency.

3. First-Line Investigations Prior to Blood Transfusion

Before a blood transfusion is administered, several tests and investigations are required to assess the need for transfusion, ensure compatibility, and monitor the patient's response. Key investigations include:

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin, haematocrit, and platelet levels, helping determine the need for RBC or platelet transfusion.

Findings:

Low Haemoglobin: Indicates anaemia that may require RBC transfusion.

Low Platelet Count: Indicates thrombocytopenia that may require platelet transfusion.

B) Blood Group and Crossmatch:

Blood Grouping (ABO and RhD):

Purpose: To determine the patient's blood type.

Findings: Identifies the ABO and RhD status to ensure compatibility between the donor's and recipient's blood.

Crossmatching:

Purpose: To test for compatibility between the donor's blood and the recipient's blood.

Findings: Confirms compatibility and prevents transfusion reactions.

C) Coagulation Profile (if indicated for plasma transfusion):

Prothrombin Time (PT) and Activated Partial Thromboplastin Time (aPTT):

Purpose: To evaluate clotting factor deficiencies.

Findings: Prolonged PT or aPTT indicates the need for FFP to correct clotting abnormalities.

Fibrinogen Levels:

Purpose: To assess for fibrinogen deficiency, especially in cases of DIC or massive transfusion.

Findings: Low fibrinogen levels (<1.5-2 g/L) indicate the need for cryoprecipitate.

D) Iron Studies (for chronic transfusions):

Purpose: To monitor for iron overload in patients receiving chronic transfusions (e.g., thalassaemia, sickle cell disease).

Findings: Elevated serum ferritin and transferrin saturation indicate iron overload, necessitating iron chelation therapy.

4. Explanation of Investigations

a) Blood Group and Crossmatch:

Procedure: A blood sample is taken from the patient and tested for ABO and RhD blood type. A crossmatch is performed by mixing the patient's serum with donor red blood cells to check for compatibility.

Interpretation: If the crossmatch is compatible, the transfusion is safe to proceed. If incompatible, the risk of transfusion reactions, including **haemolysis**, is high.

5. Types of Blood Products Used in Transfusion

There are several types of blood products used depending on the clinical indication:

A) Packed Red Blood Cells (PRBCs):

Indication: To treat symptomatic anaemia or acute blood loss.

Contents: Concentrated red blood cells with most of the plasma removed.

Effect: Each unit of PRBCs typically raises haemoglobin by approximately **10 g/L**.

B) Platelets:

Indication: For patients with thrombocytopenia or platelet dysfunction, either prophylactically or to control active bleeding.

Contents: Platelets suspended in plasma.

Effect: Each platelet transfusion typically raises platelet counts by **20-40 x 10⁹/L**.

C) Fresh Frozen Plasma (FFP):

Indication: To replace clotting factors in conditions such as DIC, liver disease, or massive transfusion.

Contents: Plasma containing clotting factors (II, V, VII, IX, X, XI).

Effect: Helps correct prolonged PT and aPTT.

D) Cryoprecipitate:

Indication: For patients with low fibrinogen levels (e.g., in massive haemorrhage or DIC).

Contents: Concentrated fibrinogen, factor VIII, von Willebrand factor, and factor XIII.

Effect: Increases fibrinogen levels to assist with clot formation.

6. First-Line Therapy and Indications for Transfusion According to NICE Guidelines

NICE guidelines provide clear indications for when to administer blood transfusions, emphasising that transfusions should be given based on clinical need and not purely on haemoglobin levels.

A) Red Blood Cell Transfusion:

Threshold for Transfusion:

Stable Adults Without Cardiovascular Disease: Consider RBC transfusion if **Hb <70 g/L**.

Adults with Cardiovascular Disease: Consider RBC transfusion if **Hb <80 g/L**.

Dose: Usually 1 unit at a time, with reassessment after each unit. Aim for the lowest transfusion volume needed to relieve symptoms or restore haemoglobin to a safe level.

B) Platelet Transfusion:

Prophylactic Transfusion: For patients with platelet counts $<10 \times 10^9/L$ who are at risk of spontaneous bleeding (e.g., chemotherapy patients).

Active Bleeding: Transfuse if platelet count is $<50 \times 10^9/L$ during active bleeding or surgery.

C) Fresh Frozen Plasma (FFP):

Indication: For patients with bleeding and **prolonged clotting times** (e.g., PT or aPTT >1.5 times normal).

Dose: 12-15 mL/kg; typically, 3-4 units for an average adult.

D) Cryoprecipitate:

Indication: For patients with **fibrinogen deficiency** (<1.5 g/L) and significant bleeding.

Dose: 1-2 pools of cryoprecipitate (each pool contains 5 units), with each pool raising fibrinogen levels by approximately 1 g/L.

7. Common Contraindications and Precautions for Blood Transfusion

A) Contraindications:

Unnecessary Transfusion: Avoid transfusion when clinical indications are not met, such as in stable patients with mild anaemia who can be managed with alternatives (e.g., iron supplementation).

Allergic Reactions: Known severe allergies to blood products or components (e.g., IgA deficiency with anti-IgA antibodies).

B) Precautions:

Transfusion-Associated Circulatory Overload (TACO): Monitor patients at risk (e.g., elderly, heart failure patients) for fluid overload. Consider using smaller transfusion volumes and diuretics.

Iron Overload: In patients receiving chronic transfusions (e.g., thalassaemia), monitor iron levels and consider iron chelation therapy if necessary.

8. Routine Monitoring and Follow-Up During and After Transfusion

A) Monitoring During Transfusion:

Vital Signs: Monitor heart rate, blood pressure, temperature, and oxygen saturation before, during, and after transfusion.

Transfusion Reactions: Monitor for signs of transfusion reactions, such as fever, chills, itching, rash, shortness of breath, or chest pain.

B) Post-Transfusion Monitoring:

Haemoglobin and Platelet Count: Check haemoglobin levels 24 hours after RBC transfusion to assess response. Platelet count should be checked 1 hour after platelet transfusion.

Iron Levels: Monitor ferritin and transferrin saturation in patients receiving chronic transfusions.

9. Complications of Blood Transfusion

A) Transfusion Reactions:

Acute Hemolytic Transfusion Reaction:

Cause: ABO incompatibility.

Symptoms: Fever, chills, flank pain, dark urine, hypotension.

Management: Stop transfusion immediately, provide supportive care, and notify the blood bank.

Febrile Non-Hemolytic Transfusion Reaction:

Cause: Cytokine release from donor white blood cells.

Symptoms: Fever and chills without haemolysis.

Management: Stop transfusion, administer antipyretics, and continue transfusion if symptoms resolve.

B) Transfusion-Related Acute Lung Injury (TRALI):

Cause: Immune-mediated reaction leading to non-cardiogenic pulmonary oedema.

Symptoms: Acute respiratory distress, hypoxia, and pulmonary infiltrates on chest X-ray.

Management: Stop transfusion, provide oxygen and supportive care.

C) Transfusion-Associated Circulatory Overload (TACO):

Cause: Rapid transfusion leading to fluid overload.

Symptoms: Dyspnoea, hypertension, pulmonary oedema.

Management: Administer diuretics and provide supportive care.

D) Iron Overload (in chronic transfusion):

Cause: Repeated blood transfusions leading to excess iron deposition in organs.

Symptoms: Fatigue, joint pain, liver dysfunction, and heart failure.

Management: Iron chelation therapy with drugs such as **deferoxamine** or **deferasirox**.

Summary of Key Points for Blood Transfusion

Blood transfusions are critical in managing conditions like severe anaemia, thrombocytopenia, coagulopathies, and acute blood loss.

Investigations such as **FBC**, **blood grouping**, and **crossmatching** are essential before transfusion.

Red blood cells, platelets, FFP, and **cryoprecipitate** are administered based on specific clinical indications, following **NICE guidelines**.

Monitoring for transfusion reactions and post-transfusion complications is vital to ensure patient safety and optimal outcomes.

224. Haematological Cancers

1. Detailed Definition of Haematological Cancers

Haematological cancers, also known as **blood cancers**, are malignancies that affect the **blood, bone marrow**, and **lymphatic system**. These cancers disrupt the production and function of blood cells, typically leading to the uncontrolled proliferation of abnormal cells. The three major types of haematological cancers include:

Leukaemia: Cancer of the bone marrow and blood, where abnormal white blood cells are produced in excess.

Lymphoma: Cancer of the lymphatic system, affecting lymphocytes, a type of white blood cell.

Multiple Myeloma: Cancer of plasma cells in the bone marrow, leading to overproduction of abnormal antibodies.

Each of these cancers has subtypes, with varying clinical presentations and treatment strategies.

2. Common Presenting Complaints and Symptoms of Haematological Cancers

The symptoms of haematological cancers can vary depending on the specific type, but common presenting features include:

A) Symptoms of Leukaemia (acute or chronic):

Fatigue and Weakness: Resulting from anaemia due to reduced red blood cell production.

Frequent Infections: Caused by a lack of normal functioning white blood cells.

Easy Bruising and Bleeding: Due to thrombocytopenia (low platelet count).

Bone Pain: Common in acute lymphoblastic leukaemia (ALL), caused by the expansion of the bone marrow.

Pallor: Due to anaemia.

Fever: Unexplained fever as a result of infection or the malignancy itself.

Swollen Lymph Nodes, Spleen, or Liver: Particularly in chronic leukaemia.

B) Symptoms of Lymphoma (Hodgkin and Non-Hodgkin):

Painless Lymphadenopathy: Enlarged lymph nodes, often in the neck, armpits, or groin.

B Symptoms: Unexplained fever, night sweats, and unintentional weight loss (commonly seen in Hodgkin lymphoma).

Itching (Pruritus): Especially common in Hodgkin lymphoma.

Fatigue: General tiredness and lethargy.

Cough or Shortness of Breath: If the lymph nodes in the chest (mediastinal nodes) are enlarged.

C) Symptoms of Multiple Myeloma:

Bone Pain and Fractures: Particularly in the back or ribs, due to lytic bone lesions.

Hypercalcaemia: Symptoms of high calcium levels, such as confusion, constipation, excessive thirst, and frequent urination.

Renal Impairment: Resulting from abnormal proteins (light chains) that damage the kidneys.

Anaemia: Resulting in fatigue, pallor, and shortness of breath.

Infections: Due to impaired production of normal antibodies.

3. First-Line Investigations for Haematological Cancers

The diagnosis of haematological cancers requires a combination of **blood tests, bone marrow biopsy, imaging**, and specialised testing to identify specific cancer subtypes.

A) Full Blood Count (FBC):

Purpose: To assess the number and type of blood cells.

Findings:

Leukaemia: Abnormal white blood cell counts (leucocytosis or leucopenia), anaemia, and thrombocytopenia.

Lymphoma: May show anaemia, thrombocytopenia, or leucopenia if bone marrow involvement is present.

Multiple Myeloma: Normocytic, normochromic anaemia is common.

B) Peripheral Blood Smear:

Purpose: To examine the morphology of blood cells.

Findings:

Leukaemia: Blast cells (immature white blood cells) in acute leukaemia, or mature but dysfunctional white cells in chronic leukaemia.

Lymphoma: Abnormal lymphocytes may be present.

Multiple Myeloma: Rouleaux formation (stacking of red blood cells due to increased plasma proteins).

C) Bone Marrow Biopsy and Aspiration:

Purpose: To assess the cellularity of the bone marrow and identify abnormal cells.

Findings:

Leukaemia: Increased blast cells (>20% in acute leukaemia).

Lymphoma: Bone marrow involvement in advanced disease.

Multiple Myeloma: Presence of abnormal plasma cells in the bone marrow.

D) Blood Chemistry and Serum Protein Electrophoresis (SPEP):

Serum Protein Electrophoresis (SPEP):

Purpose: To identify abnormal proteins (monoclonal gammopathy) in the blood.

Findings: M-protein spike, which is characteristic of multiple myeloma.

Calcium, Urea, and Creatinine:

Purpose: To assess for **hypercalcaemia** and **renal impairment** in multiple myeloma.

Findings: Elevated calcium, urea, and creatinine levels.

E) Lactate Dehydrogenase (LDH):

Purpose: Elevated LDH levels are a marker of cell turnover and tumour burden.

Findings: Commonly elevated in aggressive leukaemia and lymphoma.

F) Imaging Studies:

CT Scan or PET-CT:

Purpose: To assess the extent of lymph node involvement in lymphoma or detect organ infiltration in advanced leukaemia.

Findings: Enlarged lymph nodes, organomegaly, or bone lesions.

Skeletal Survey or MRI (for multiple myeloma):

Purpose: To detect lytic bone lesions.

Findings: Punched-out lesions in bones, particularly in the skull, spine, and pelvis.

G) Flow Cytometry:

Purpose: To identify specific markers on the surface of cancer cells.

Findings: Helps differentiate between different types of leukaemia and lymphoma by identifying specific cell surface antigens (e.g., CD20 in B-cell lymphoma).

H) Cytogenetics and Molecular Testing:

Purpose: To detect specific genetic abnormalities or mutations.

Findings:

Leukaemia: Common genetic mutations include the **Philadelphia chromosome** (t[9;22]) in chronic myeloid leukaemia (CML).

Lymphoma: Genetic rearrangements such as **BCL2** in follicular lymphoma or **MYC** in Burkitt lymphoma.

Multiple Myeloma: Genetic abnormalities such as **del(17p)** or **t(4;14)** may predict prognosis.

4. Explanation of Investigations

a) Bone Marrow Biopsy:

Procedure: A sample of bone marrow is taken, usually from the hip bone, to evaluate the types and proportions of cells present.

Interpretation: The presence of abnormal cells such as **blasts** (in leukaemia) or **plasma cells** (in multiple myeloma) confirms the diagnosis.

b) Serum Protein Electrophoresis (SPEP):

Procedure: A blood sample is separated by electrical charge to identify abnormal proteins.

Interpretation: The presence of an M-protein spike indicates **monoclonal gammopathy**, typical of multiple myeloma.

5. First-Line Therapy According to NICE Guidelines

A) Leukaemia:

Acute Leukaemia (Acute Myeloid Leukaemia [AML], Acute Lymphoblastic Leukaemia [ALL]):

Chemotherapy:

Induction Therapy: Aimed at achieving remission by killing leukaemic cells. Regimens vary but commonly include **cytarabine** and **anthracyclines** (e.g., daunorubicin).

Consolidation Therapy: Given after remission to eradicate any remaining disease.

Targeted Therapy (if applicable):

Imatinib for patients with **Philadelphia chromosome-positive ALL**.

Bone Marrow Transplant: May be indicated in high-risk patients.

Chronic Leukaemia (Chronic Myeloid Leukaemia [CML], Chronic Lymphocytic Leukaemia [CLL]):

Tyrosine Kinase Inhibitors (TKIs) (for CML):

Imatinib or newer agents (e.g., dasatinib, nilotinib).

Chemotherapy and Immunotherapy (for CLL):

Fludarabine, cyclophosphamide, and rituximab.

B) Lymphoma:

Hodgkin Lymphoma (HL):

ABVD Chemotherapy Regimen: Includes **doxorubicin, bleomycin, vinblastine, and dacarbazine.**

Radiotherapy: Used in early-stage disease, often following chemotherapy.

Non-Hodgkin Lymphoma (NHL):

R-CHOP Chemotherapy Regimen (for aggressive B-cell lymphomas):

Rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone.

Targeted Therapy:

Brentuximab vedotin for relapsed Hodgkin lymphoma.

C) Multiple Myeloma:

Induction Therapy:

Bortezomib, thalidomide, and dexamethasone (BTD regimen).

Lenalidomide may be used in certain cases.

Stem Cell Transplant: Considered in younger or fit patients after initial chemotherapy.

Supportive Therapy:

Bisphosphonates (e.g., zoledronic acid) to treat bone disease and prevent fractures.

Plasmapheresis: To remove excess light chains in severe renal impairment.

6. Common Contraindications and Second-Line Therapy

A) Contraindications:

Chemotherapy: Avoid certain chemotherapy agents in patients with severe liver or kidney dysfunction.

Stem Cell Transplant: Not suitable for elderly or frail patients due to the high risk of complications.

B) Second-Line Therapy:

CAR-T Cell Therapy: In relapsed or refractory B-cell lymphomas or leukaemia.

Monoclonal Antibodies:

Daratumumab: Used in relapsed or refractory multiple myeloma.

Immunomodulatory Drugs:

Pomalidomide: For relapsed multiple myeloma.

7. Routine Monitoring and Follow-Up

A) Full Blood Count and Biochemistry:

Regular monitoring of blood counts, kidney function, and calcium levels is essential, especially in patients receiving chemotherapy.

B) Bone Marrow Biopsy:

Repeated to assess response to therapy, especially in leukaemia.

C) Imaging:

PET-CT or **CT Scans** for lymphoma staging and assessing treatment response.

8. Complications of Haematological Cancers

A) Tumour Lysis Syndrome:

Cause: Rapid breakdown of cancer cells during treatment, leading to hyperuricaemia, hyperkalaemia, and renal failure.

Management: Aggressive hydration, **allopurinol**, or **rasburicase**.

B) Bone Marrow Failure:

Cause: Replacement of normal marrow cells by cancer cells, leading to pancytopenia.

Management: Supportive care with transfusions and growth factors.

C) Infections:

Cause: Immunosuppression due to cancer or chemotherapy.

Management: Prophylactic antibiotics, antifungals, and antivirals.

Summary of Key Points for Haematological Cancers

Haematological cancers include leukaemia, lymphoma, and multiple myeloma, each presenting with specific symptoms such as anaemia, infections, and organ involvement.

Diagnosis requires blood tests, bone marrow biopsy, and imaging, while **treatment** follows guidelines such as chemotherapy, targeted therapy, and stem cell transplants.

Monitoring involves regular blood counts, imaging, and assessing treatment response.

Complications like tumour lysis syndrome and infections require prompt management.

225. Chronic Liver Disease and Its Haematological Manifestations

1. Detailed Definition of Chronic Liver Disease

Chronic liver disease (CLD) refers to a progressive deterioration of liver function over a period of six months or more, often due to **chronic inflammation, fibrosis, or cirrhosis**. It is caused by various aetiologies, including **viral hepatitis (Hepatitis B and C), alcoholic liver disease, non-alcoholic fatty liver disease (NAFLD), and autoimmune liver diseases**. The liver plays a vital role in producing clotting factors, regulating haemostasis, and processing blood cells; hence, CLD is associated with various haematological complications.

2. Common Presenting Complaints and Symptoms of Chronic Liver Disease

Patients with chronic liver disease often present with a range of systemic and haematological symptoms due to impaired liver function:

A) General Symptoms:

Fatigue: Generalised tiredness due to impaired metabolism and nutrient deficiencies.

Jaundice: Yellowing of the skin and eyes due to elevated bilirubin levels.

Abdominal Distension: Due to ascites (fluid accumulation in the abdomen).

Pruritus: Itching caused by bile salt retention.

Weight Loss: Unintentional weight loss, especially in cirrhosis or advanced liver disease.

B) Symptoms of Portal Hypertension:

Gastrointestinal Bleeding: From **oesophageal varices** or **gastric varices**.

Splenomegaly: Enlarged spleen due to portal hypertension, which can lead to **hypersplenism** and pancytopenia.

C) Haematological Symptoms:

Easy Bruising and Bleeding: Due to decreased production of clotting factors.

Anaemia: Can be from chronic blood loss (varices), hypersplenism, or nutritional deficiencies.

Pallor: Pale skin or mucous membranes from anaemia.

Petechiae or Purpura: Small red or purple spots due to thrombocytopenia.

3. First-Line Investigations for Chronic Liver Disease and Haematological Complications

To assess liver function and its impact on haematology, a combination of blood tests, imaging, and specific liver-related investigations are needed:

A) Full Blood Count (FBC):

Purpose: To assess for anaemia, thrombocytopenia, and leukopenia.

Findings:

Anaemia: May be normocytic or microcytic due to chronic blood loss (e.g., from varices) or macrocytic from alcohol-related liver disease.

Thrombocytopenia: Low platelet count due to **hypersplenism** or reduced thrombopoietin production by the liver.

Leukopenia: Low white blood cell count, often due to hypersplenism.

B) Liver Function Tests (LFTs):

Alanine Aminotransferase (ALT) and Aspartate Aminotransferase (AST):

Purpose: To evaluate liver cell damage.

Findings: Elevated in active liver injury (hepatitis), may normalise in end-stage liver disease due to loss of hepatocytes.

Bilirubin:

Purpose: To assess liver function related to bilirubin processing.

Findings: Elevated bilirubin in cholestasis or impaired conjugation (jaundice).

Albumin:

Purpose: To assess synthetic function of the liver.

Findings: Low levels indicate poor liver synthetic capacity.

Prothrombin Time (PT) / International Normalised Ratio (INR):

Purpose: To assess coagulation and liver synthetic function (production of clotting factors).

Findings: Prolonged PT/INR indicates decreased production of clotting factors, particularly factors II, V, VII, IX, and X.

C) Coagulation Profile:

Prothrombin Time (PT) / INR:

Purpose: To assess for coagulopathy due to reduced clotting factor synthesis.

Findings: Prolonged PT/INR, reflecting impaired production of coagulation factors.

D) Fibrinogen Levels:

Purpose: To evaluate fibrinogen, which is also produced by the liver.

Findings: Low fibrinogen levels in advanced liver disease indicate reduced clotting ability.

E) Ultrasound of the Liver:

Purpose: To assess for structural changes, including cirrhosis, portal hypertension, and splenomegaly.

Findings: Nodular liver texture (cirrhosis), splenomegaly, ascites, and evidence of portal hypertension.

F) Endoscopy:

Purpose: To evaluate for **oesophageal varices** or **gastric varices**, which are a common source of bleeding in portal hypertension.

Findings: Enlarged veins in the oesophagus or stomach, which may require banding or other interventions to prevent rupture.

G) Serum Ferritin and Iron Studies (if haemochromatosis is suspected):

Purpose: To assess for iron overload as a cause of liver disease.

Findings: Elevated ferritin and transferrin saturation in **hereditary haemochromatosis**.

4. Explanation of Investigations

a) Full Blood Count (FBC):

Procedure: A blood sample is tested to measure red blood cells, white blood cells, and platelets.

Interpretation: Chronic liver disease commonly presents with **pancytopenia** (anaemia, thrombocytopenia, and leukopenia) due to **hypersplenism**.

b) Coagulation Profile (INR/PT):

Procedure: Measures the time it takes for blood to clot.

Interpretation: A prolonged INR or PT reflects the liver's reduced ability to synthesise clotting factors, increasing the risk of bleeding.

5. Haematological Complications in Chronic Liver Disease

Several haematological complications are associated with chronic liver disease, primarily due to impaired liver function, portal hypertension, and hypersplenism.

A) Coagulopathy:

Cause: The liver produces most of the body's clotting factors (e.g., factors II, V, VII, IX, X), and impaired liver function leads to reduced synthesis of these factors.

Presentation: Prolonged bleeding after minor trauma or invasive procedures, easy bruising, and prolonged PT/INR.

Management:

Fresh Frozen Plasma (FFP): Administered to replace clotting factors in bleeding patients.

Vitamin K: Useful in correcting coagulopathy due to reduced vitamin K absorption (common in cholestasis).

B) Thrombocytopenia:

Cause: Portal hypertension causes **splenomegaly**, leading to increased sequestration of platelets in the spleen (hypersplenism). Additionally, reduced thrombopoietin production by the liver decreases platelet production.

Presentation: Easy bruising, petechiae, purpura, and prolonged bleeding.

Management:

Platelet Transfusion: May be required before invasive procedures or in active bleeding.

Splenectomy (rarely considered): May be considered in severe cases of hypersplenism.

C) Anaemia:

Cause: Multifactorial, including chronic blood loss from **oesophageal varices**, **hypersplenism** (causing increased destruction of red blood cells), and **nutritional deficiencies** (iron, folate, B12).

Presentation: Fatigue, pallor, and dyspnoea on exertion.

Management:

Iron Supplementation: For patients with iron deficiency anaemia due to chronic bleeding.

Blood Transfusions: For severe anaemia or acute blood loss.

D) Disseminated Intravascular Coagulation (DIC):

Cause: Advanced liver disease can lead to a procoagulant state, which may trigger DIC, causing widespread clotting and subsequent bleeding.

Management:

FFP and **cryoprecipitate** to replace clotting factors.

Treat underlying liver failure.

6. First-Line Therapy for Haematological Complications in Chronic Liver Disease

Management focuses on correcting the underlying liver dysfunction and treating haematological complications based on severity:

A) Vitamin K Supplementation:

Indication: Given to patients with **cholestasis** or **prolonged INR** due to impaired vitamin K absorption.

Dose: 10 mg IV over several days if deficiency is suspected.

Outcome: Corrects coagulopathy if related to vitamin K deficiency.

B) Fresh Frozen Plasma (FFP):

Indication: For patients with bleeding and prolonged INR/PT due to clotting factor deficiencies.

Dose: 10-15 mL/kg, repeated as necessary based on clinical response and INR/PT levels.

Outcome: Temporarily restores clotting factors.

C) Platelet Transfusion:

Indication: For severe **thrombocytopenia** ($<50 \times 10^9/L$) with active bleeding or prior to invasive procedures.

Dose: One unit of platelets increases the platelet count by approximately $20-40 \times 10^9/L$.

D) Blood Transfusions:

Indication: For patients with significant anaemia (Hb $<70-80$ g/L) or acute blood loss (e.g., from oesophageal varices).

Dose: One unit of packed red blood cells (PRBCs) typically raises haemoglobin by 10 g/L.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Vitamin K Supplementation: Should be used cautiously in patients with active liver failure and DIC, where clotting derangements are not due to vitamin K deficiency.

B) Second-Line Therapy:

Terlipressin and Endoscopic Therapy:

Indication: For bleeding oesophageal varices. Terlipressin reduces portal pressure, and endoscopic band ligation controls variceal bleeding.

Splenectomy (in rare cases):

Indication: For severe **hypersplenism** causing symptomatic pancytopenia, unresponsive to conservative treatment.

8. Routine Monitoring and Follow-Up

A) Full Blood Count and Coagulation Tests:

Frequency: Regular monitoring every 1-3 months or more frequently in actively bleeding patients.

Purpose: To track anaemia, thrombocytopenia, and coagulopathy.

B) Liver Function Tests (LFTs):

Frequency: Every 3-6 months to monitor liver function and progression of disease.

C) Endoscopic Surveillance:

Frequency: Regular screening for **oesophageal varices** in patients with cirrhosis, typically every 2-3 years.

9. Complications of Haematological Disorders in Chronic Liver Disease

A) Variceal Bleeding:

Cause: Rupture of oesophageal or gastric varices due to portal hypertension.

Management: Endoscopic banding, **terlipressin**, and blood transfusions.

B) Hepatic Encephalopathy:

Cause: Accumulation of toxins (e.g., ammonia) due to liver failure, affecting brain function.

Management: **Lactulose** and **rifaximin** to reduce ammonia levels.

C) Hepatocellular Carcinoma:

Cause: Chronic liver disease, particularly cirrhosis, is a major risk factor.

Management: Regular surveillance with **ultrasound** and **alpha-fetoprotein (AFP)** testing.

Summary of Key Points for Haematological Complications in Chronic Liver Disease

Chronic liver disease affects the production of clotting factors and blood cells, leading to complications such as **coagulopathy**, **thrombocytopenia**, and **anaemia**.

Investigations include **FBC**, **LFTs**, **coagulation profiles**, and **endoscopy** for variceal assessment.

Management includes **vitamin K**, **FFP**, **platelet transfusions**, and treating complications like variceal bleeding.

Monitoring focuses on regular blood tests and endoscopic surveillance to manage complications and progression of liver disease.

226. Essential Thrombocythemia

1. Detailed Definition of Essential Thrombocythemia

Essential thrombocythaemia (ET) is a type of **myeloproliferative disorder** (MPD) characterised by the overproduction of **platelets** in the bone marrow without an identifiable cause, such as inflammation or infection. It leads to persistently elevated platelet counts (**thrombocytosis**) and can cause an increased risk of both **thrombotic** (clotting) and **haemorrhagic** (bleeding) complications. ET primarily affects adults, and while some patients are asymptomatic, others may experience symptoms related to abnormal platelet function.

ET is often associated with mutations in the **JAK2**, **CALR**, or **MPL** genes, which drive the abnormal proliferation of megakaryocytes (the precursor cells to platelets).

2. Common Presenting Complaints and Symptoms of Essential Thrombocythemia

Many patients with ET are asymptomatic and are diagnosed incidentally during routine blood tests. However, symptomatic patients may present with:

A) Thrombotic Events (most common presentation):

Deep Vein Thrombosis (DVT): Pain, swelling, and redness of the affected limb.

Pulmonary Embolism (PE): Shortness of breath, chest pain, and haemoptysis.

Ischaemic Stroke: Sudden weakness, difficulty speaking, or visual disturbances.

Transient Ischaemic Attack (TIA): Temporary stroke-like symptoms (weakness, slurred speech).

Coronary Artery Thrombosis: Chest pain or myocardial infarction.

B) Microvascular Symptoms (due to small vessel occlusions):

Erythromelalgia: Burning pain, warmth, and redness in the hands or feet.

Digital Ischaemia: Pain or tingling in the fingers and toes, with potential ulceration or gangrene in severe cases.

Headache: Persistent or episodic headaches, sometimes accompanied by visual disturbances or dizziness.

C) Haemorrhagic Complications:

Easy Bruising: Spontaneous bruises, especially on the limbs.

Epistaxis: Nosebleeds.

Gastrointestinal Bleeding: Blood in the stool or vomit (rare but possible in advanced cases).

D) Constitutional Symptoms (less common, associated with advanced disease):

Fatigue: Chronic tiredness and weakness.

Night Sweats: Occasional sweating during sleep.

Weight Loss: Unexplained loss of weight.

3. First-Line Investigations for Essential Thrombocythemia

The diagnosis of ET is typically confirmed after excluding secondary causes of thrombocytosis (such as infection, inflammation, or iron deficiency). The following tests are used:

A) Full Blood Count (FBC):

Purpose: To assess the number and type of blood cells.

Findings:

Thrombocytosis: Platelet count is elevated, typically $>450 \times 10^9/L$ (normal range: $150-400 \times 10^9/L$).

Normal Red and White Blood Cells: While anaemia or leukocytosis may sometimes be present, the absence of marked abnormalities in red or white blood cells is typical.

B) Peripheral Blood Smear:

Purpose: To examine the morphology of blood cells.

Findings:

Large and Giant Platelets: Abnormally large platelets may be seen, indicating abnormal megakaryocyte activity.

C) JAK2, CALR, and MPL Mutation Testing:

Purpose: To identify mutations commonly associated with ET.

Findings:

JAK2 V617F Mutation: Present in approximately 50-60% of ET cases.

CALR or MPL Mutations: Found in approximately 25% of cases without the JAK2 mutation.

D) Bone Marrow Biopsy (if indicated):

Purpose: To assess bone marrow cellularity and exclude other myeloproliferative or myelodysplastic conditions.

Findings:

Increased Megakaryocytes: Large and atypical megakaryocytes (precursors to platelets) with no significant increase in red or white blood cell precursors.

E) Serum Ferritin and Iron Studies:

Purpose: To exclude iron deficiency as a cause of reactive thrombocytosis.

Findings: Normal or elevated ferritin, ruling out iron deficiency.

4. Explanation of Investigations

a) JAK2 Mutation Testing:

Procedure: A blood sample is analysed for the presence of the **JAK2 V617F mutation**.

Interpretation: If positive, the presence of the JAK2 mutation supports the diagnosis of a myeloproliferative disorder such as ET. If negative, CALR and MPL mutations should be tested.

5. Diagnostic Criteria for Essential Thrombocythemia

The **WHO diagnostic criteria** for ET include the following:

Major Criteria:

Platelet Count $>450 \times 10^9/L$.

Bone Marrow Biopsy showing proliferation of megakaryocytes with little or no increase in granulocytes or erythrocytes.

Presence of **JAK2, CALR, or MPL mutations**.

Exclusion of other causes of thrombocytosis, such as iron deficiency, inflammation, or other myeloproliferative neoplasms (e.g., polycythaemia vera).

Minor Criteria:

Presence of **clonal markers** or absence of evidence for reactive thrombocytosis.

A diagnosis of ET is made when all **4 major criteria** or the first **3 major criteria** and the **minor criterion** are met.

6. First-Line Therapy According to Guidelines

NICE guidelines and other expert consensus recommend risk stratifying patients based on their risk of thrombotic events and tailoring treatment accordingly.

A) Low-Risk Patients (age <60, no history of thrombosis, JAK2-negative):

Aspirin:

Dose: 75-100 mg daily.

Mechanism: Reduces the risk of clot formation by inhibiting platelet aggregation.

Use: Recommended for patients with low thrombotic risk to reduce the risk of arterial and venous thrombosis.

B) High-Risk Patients (age >60, previous thrombotic events, or JAK2-positive):

Cytoreductive Therapy:

Hydroxycarbamide (Hydroxyurea):

Dose: 500 mg to 1 g daily (titrated to maintain platelet counts below $400 \times 10^9/L$).

Mechanism: Suppresses bone marrow activity, reducing platelet production.

Use: First-line therapy for patients at high risk of thrombosis.

Anagrelide (if hydroxyurea is not tolerated):

Dose: 0.5-1.5 mg daily, adjusted to maintain platelet counts.

Mechanism: Reduces platelet production by inhibiting megakaryocyte maturation.

Interferon- α (especially in younger patients or during pregnancy):

Mechanism: Suppresses bone marrow activity and reduces platelet production without teratogenic effects.

Aspirin:

Low-dose aspirin is generally used alongside cytoreductive therapy in high-risk patients to further reduce the risk of thrombotic events.

C) Management of Bleeding:

In patients with a history of bleeding or very high platelet counts ($>1,500 \times 10^9/L$), consider withholding aspirin due to the increased risk of haemorrhage, and focus on cytoreductive therapy to reduce the platelet count.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Hydroxycarbamide: Avoid in pregnant women or those planning to conceive, as it can be teratogenic.

Aspirin: Avoid in patients with a history of gastrointestinal bleeding, peptic ulcer disease, or very high platelet counts ($>1,500 \times 10^9/L$), where the risk of bleeding may outweigh the benefits.

B) Second-Line Therapy:

Anagrelide: Used in patients who are intolerant to hydroxycarbamide.

Interferon- α : May be used in younger patients or those unable to tolerate other cytoreductive therapies, as it has a safer profile in pregnancy.

8. Routine Monitoring and Follow-Up

A) Full Blood Count (FBC):

Frequency: Every 3-6 months to monitor platelet counts and the response to therapy.

Target: Maintain platelet counts $<400 \times 10^9/L$ to reduce thrombotic risk.

B) Monitoring for Complications:

Thrombotic Events: Regular clinical assessment for signs of DVT, stroke, or other thrombotic complications.

Bleeding: Monitor for signs of easy bruising, epistaxis, or gastrointestinal bleeding, especially in patients on aspirin.

C) Bone Marrow Biopsy:

Frequency: May be repeated during follow-up if there are concerns about disease progression or transformation to **myelofibrosis** or **acute leukaemia**.

9. Complications of Essential Thrombocythemia

A) Thrombotic Events:

Cause: High platelet counts increase the risk of arterial and venous thrombosis.

Management: Antiplatelet therapy with aspirin and cytoreductive therapy (hydroxycarbamide) to reduce platelet counts and prevent clots.

B) Haemorrhagic Events:

Cause: Paradoxically, very high platelet counts ($>1,500 \times 10^9/L$) can cause platelet dysfunction, leading to bleeding.

Management: Cytoreductive therapy to lower platelet counts, and careful use of antiplatelet agents.

C) Disease Transformation:

Risk: ET can transform into **myelofibrosis** (secondary myelofibrosis) or **acute myeloid leukaemia (AML)** in a small proportion of patients.

Management: Close monitoring and bone marrow biopsies if transformation is suspected.

Summary of Key Points for Essential Thrombocythemia (ET)

Essential thrombocythaemia (ET) is a myeloproliferative disorder characterised by persistent **thrombocytosis** and an increased risk of **thrombosis** and **bleeding**.

Diagnosis involves elevated platelet counts, bone marrow findings, and testing for **JAK2**, **CALR**, or **MPL mutations**.

Treatment is based on risk stratification, with **aspirin** for low-risk patients and **cytoreductive therapy** (e.g., hydroxycarbamide) for high-risk patients.

Monitoring includes regular blood counts and assessment for complications such as **thrombosis**, **bleeding**, and **disease transformation**.

227. Haemochromatosis and Iron Overload

1. Detailed Definition of Haemochromatosis and Iron Overload

Haemochromatosis is a genetic disorder characterised by excessive absorption of **dietary iron** from the gastrointestinal tract, leading to **iron overload** in the body. This excess iron is deposited in various organs, including the **liver**, **heart**, **pancreas**, and **joints**, potentially leading to organ damage over time.

There are two main types of haemochromatosis:

Hereditary Haemochromatosis (HHC): Caused by mutations in the **HFE gene**, particularly the **C282Y** and **H63D** mutations. It is the most common genetic cause of iron overload.

Secondary Iron Overload: Occurs due to other conditions, such as **chronic transfusions** (e.g., in thalassaemia or sickle cell disease), chronic liver disease, or excessive oral iron intake.

If untreated, haemochromatosis can lead to **cirrhosis**, **diabetes mellitus**, **cardiomyopathy**, and **joint disease**. Early detection and treatment can prevent organ damage and improve outcomes.

2. Common Presenting Complaints and Symptoms of Haemochromatosis

A) Early Symptoms (often non-specific):

Fatigue: Persistent tiredness and lack of energy.

Joint Pain: Particularly in the **hands**, especially affecting the **knuckles** of the first and second fingers.

Abdominal Pain: Vague or diffuse pain, typically in the upper right quadrant.

Weakness: Generalised muscle weakness or lethargy.

Loss of Libido or Erectile Dysfunction: Due to hypogonadism.

B) Advanced Symptoms (due to organ damage from iron deposition):

Skin Hyperpigmentation ("Bronze Diabetes"): A bronzed or greyish skin discolouration, especially in sun-exposed areas.

Diabetes Mellitus: Due to iron deposition in the pancreas, affecting insulin production.

Liver Disease: Ranging from **hepatomegaly** (enlarged liver) to **cirrhosis** in advanced cases.

Heart Disease: Cardiomyopathy, leading to arrhythmias, heart failure, or sudden death.

Arthritis: Particularly in the hands, knees, and ankles, caused by iron deposition in the joints.

Hypogonadism: Iron deposition in the pituitary gland may cause low testosterone levels in men, leading to impotence and infertility.

3. First-Line Investigations for Haemochromatosis and Iron Overload

To diagnose haemochromatosis or assess iron overload, several tests are needed to measure iron levels in the blood and assess organ damage.

A) Serum Ferritin:

Purpose: Measures the amount of stored iron in the body.

Findings:

Elevated Ferritin: >300 µg/L in men and postmenopausal women, or >200 µg/L in premenopausal women, suggests iron overload.

B) Transferrin Saturation:

Purpose: Measures the percentage of transferrin (the protein that transports iron) that is bound to iron.

Findings:

Increased Transferrin Saturation: >45% is suggestive of iron overload, especially in hereditary haemochromatosis.

C) HFE Genetic Testing:

Purpose: To confirm a diagnosis of hereditary haemochromatosis by detecting mutations in the HFE gene.

Findings:

C282Y Homozygosity: Present in 80-90% of patients with hereditary haemochromatosis.

H63D Homozygosity or Compound Heterozygosity (C282Y/H63D): Associated with a milder form of the disease or variable penetrance.

D) Liver Function Tests (LFTs):

Purpose: To assess liver damage or cirrhosis.

Findings:

Elevated **ALT** and **AST** may indicate liver inflammation or damage.

E) MRI Liver (if indicated):

Purpose: To quantify iron deposition in the liver and assess the degree of liver fibrosis or cirrhosis.

Findings:

Increased Hepatic Iron Content: Suggests significant iron overload.

F) Liver Biopsy (if indicated):

Purpose: To directly assess the degree of iron deposition and liver damage (especially in cases of suspected cirrhosis).

Findings:

Increased Iron Staining in liver tissue (using Prussian blue stain).

Fibrosis or **cirrhosis** may be present in advanced cases.

G) Electrocardiogram (ECG) and Echocardiogram:

Purpose: To evaluate heart function in patients with symptoms of cardiomyopathy.

Findings:

ECG may show **arrhythmias**.

Echocardiogram may show **dilated cardiomyopathy** or reduced ejection fraction.

4. Explanation of Investigations

a) Serum Ferritin:

Procedure: A blood test measures ferritin, a protein that stores iron in the body.

Interpretation: Elevated ferritin levels suggest increased iron stores, but ferritin can also be raised in inflammatory conditions, so it must be interpreted alongside transferrin saturation and other tests.

5. Diagnostic Criteria for Haemochromatosis

The diagnosis of hereditary haemochromatosis is based on the following criteria:

Elevated Transferrin Saturation: >45%.

Elevated Serum Ferritin: >300 µg/L in men and >200 µg/L in women.

HFE Genetic Mutation: C282Y homozygosity (or compound heterozygosity with H63D).

Exclusion of Other Causes: Exclude secondary causes of iron overload (e.g., chronic transfusion, liver disease).

In patients with advanced disease, additional tests such as liver biopsy or MRI to assess iron deposition and liver damage may be necessary.

6. First-Line Therapy According to Guidelines

NICE guidelines and other clinical protocols recommend early intervention to prevent organ damage in patients with haemochromatosis. The goal of treatment is to reduce excess iron stores through regular blood removal (phlebotomy) and manage complications.

A) Phlebotomy:

Venesection:

Procedure: Regular removal of blood (usually 500 mL), which reduces the body's iron stores by removing iron-containing red blood cells.

Frequency: Initially 1-2 times per week until ferritin levels are reduced to the target range (50-100 µg/L). After this, maintenance phlebotomy is done every 2-4 months.

Outcome: Effective in preventing organ damage and reversing some symptoms of iron overload.

B) Dietary Advice:

Avoid Iron Supplements: Patients should avoid any iron supplements, as they can exacerbate iron overload.

Limit Vitamin C: Excessive vitamin C can increase iron absorption, so supplementation should be avoided unless clinically indicated.

Alcohol Reduction: Alcohol can exacerbate liver damage in patients with iron overload, so it should be limited.

C) Management of Organ-Specific Complications:

Liver Disease:

Surveillance for Cirrhosis: Regular screening for hepatocellular carcinoma (HCC) with **ultrasound** and **alpha-fetoprotein (AFP)** levels every 6 months in patients with cirrhosis.

Liver Transplant: Considered for end-stage liver disease or liver failure due to cirrhosis.

Diabetes:

Management of Diabetes: Lifestyle modification, oral hypoglycaemic agents, or insulin therapy, as required.

Heart Disease:

Heart Failure Management: Medications such as **ACE inhibitors**, **beta-blockers**, and **diuretics** may be used in patients with cardiomyopathy.

Arthritis:

Symptomatic Relief: Non-steroidal anti-inflammatory drugs (NSAIDs) or **physiotherapy** to manage joint pain and stiffness.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Iron Chelation Therapy: Generally not required in hereditary haemochromatosis unless venesection is contraindicated (e.g., in severe anaemia or heart failure). However, iron chelation may be used in secondary iron overload conditions (e.g., chronic transfusions).

Phlebotomy in Severe Anaemia: Avoid phlebotomy if the patient has symptomatic anaemia. Other treatment options may need to be considered.

B) Second-Line Therapy:

Iron Chelation Therapy (for patients who cannot tolerate phlebotomy):

Deferasirox or Deferoxamine:

Mechanism: Binds to excess iron and promotes its excretion in urine or faeces.

Use: Primarily used in patients with iron overload due to chronic transfusions (e.g., thalassaemia) or in rare cases of hereditary haemochromatosis where venesection is not possible.

8. Routine Monitoring and Follow-Up

A) Serum Ferritin and Transferrin Saturation:

Frequency: Every 3 months during initial treatment and annually once ferritin levels are stabilised.

Target: Maintain serum ferritin between 50-100 µg/L and transferrin saturation <45%.

B) Liver Function Tests (LFTs):

Frequency: Every 6-12 months, particularly in patients with liver disease.

Purpose: To monitor for signs of liver damage or progression to cirrhosis.

C) Screening for Complications:

Liver Ultrasound and AFP Levels: Every 6 months for patients with cirrhosis to monitor for hepatocellular carcinoma.

Diabetes Screening: Regular blood glucose monitoring in patients with known or suspected diabetes.

9. Complications of Haemochromatosis and Iron Overload

A) Cirrhosis and Liver Cancer:

Cause: Chronic iron deposition in the liver leads to fibrosis and cirrhosis, increasing the risk of hepatocellular carcinoma.

Management: Regular screening for liver cancer and management of liver failure.

B) Cardiomyopathy:

Cause: Iron deposition in the heart muscle can lead to dilated or restrictive cardiomyopathy, causing heart failure and arrhythmias.

Management: Medications for heart failure and iron removal through phlebotomy or chelation therapy.

C) Diabetes Mellitus:

Cause: Iron deposition in the pancreas impairs insulin production, leading to diabetes.

Management: Lifestyle modification, oral hypoglycaemic agents, or insulin.

D) Joint Disease:

Cause: Iron deposition in the joints leads to chronic arthritis, particularly in the hands.

Management: NSAIDs, joint injections, or physiotherapy for pain relief.

Summary of Key Points for Haemochromatosis and Iron Overload

Haemochromatosis is a genetic disorder causing **iron overload**, with the most common form being hereditary haemochromatosis due to **HFE gene mutations**.

Diagnosis is based on elevated **serum ferritin**, **transferrin saturation**, and genetic testing for **HFE mutations**.

Phlebotomy is the mainstay of treatment, reducing iron stores and preventing organ damage. In severe cases, **iron chelation therapy** may be used.

Monitoring includes regular assessment of iron levels, liver function, and screening for complications such as **cirrhosis**, **cardiomyopathy**, and **diabetes**.

228. Autoimmune Haemolytic Anaemia (AIHA)

1. Detailed Definition of Autoimmune Haemolytic Anaemia (AIHA)

Autoimmune haemolytic anaemia (AIHA) is a type of **haemolytic anaemia** in which the body's immune system produces **antibodies** that target and destroy its own **red blood cells (RBCs)**, leading to their premature destruction (haemolysis). AIHA is classified based on the temperature at which the antibodies bind to RBCs:

Warm AIHA: Antibodies (usually IgG) bind to RBCs at body temperature (37°C). This is the more common form.

Cold AIHA (Cold Agglutinin Disease): Antibodies (usually IgM) bind to RBCs at cooler temperatures, typically in the extremities (<30°C).

AIHA can be **primary** (idiopathic) or **secondary** to other conditions, such as **autoimmune disorders, infections, malignancies, or drug-induced**.

2. Common Presenting Complaints and Symptoms of AIHA

Symptoms of AIHA result from the anaemia and haemolysis, and may vary depending on the severity and speed of onset.

A) General Symptoms of Anaemia:

Fatigue: Persistent tiredness and reduced physical endurance.

Pallor: Pale skin or mucous membranes.

Shortness of Breath: Exertional dyspnoea due to reduced oxygen-carrying capacity.

Tachycardia: Compensatory increase in heart rate due to low haemoglobin levels.

Dizziness or Lightheadedness: Particularly with severe anaemia.

B) Symptoms of Haemolysis:

Jaundice: Yellowing of the skin and eyes due to increased bilirubin from red blood cell breakdown.

Dark Urine: Haemoglobinuria (presence of haemoglobin in the urine) due to intravascular haemolysis.

Splenomegaly: Enlargement of the spleen due to increased clearance of antibody-coated RBCs.

Back or Abdominal Pain: Due to the destruction of RBCs in the spleen or liver.

C) Symptoms of Cold AIHA:

Cold-Induced Symptoms: Acrocyanosis (bluish discoloration) or numbness in the fingers, toes, or ears when exposed to cold temperatures.

Raynaud's Phenomenon: Cold-induced changes in skin colour (white, blue, red) in the extremities.

3. First-Line Investigations for Autoimmune Haemolytic Anaemia

Several blood tests and specialised investigations are required to diagnose AIHA and assess the extent of haemolysis.

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels, red blood cell count, and morphology.

Findings:

Anaemia: Haemoglobin is reduced.

Reticulocytosis: Elevated reticulocyte count, indicating increased red blood cell production in response to haemolysis.

Normocytic or Macrocytic Anaemia: AIHA typically presents as normocytic anaemia, but may be macrocytic if there is significant reticulocytosis.

B) Blood Film:

Purpose: To assess the morphology of red blood cells.

Findings:

Spherocytes: Small, round RBCs seen in warm AIHA.

Agglutination: Clumping of RBCs, seen in cold AIHA (cold agglutinin disease).

C) Direct Antiglobulin Test (DAT) or Coombs' Test:

Purpose: To detect antibodies or complement proteins bound to the surface of RBCs.

Findings:

Positive DAT: Confirms AIHA by detecting antibodies (usually IgG) or complement (C3) on RBCs.

Warm AIHA: Typically IgG positive and sometimes C3 positive.

Cold AIHA: Typically C3 positive, and IgM antibodies are found.

D) Indirect Antiglobulin Test (IAT):

Purpose: To detect free antibodies in the patient's plasma.

Findings: Often positive in AIHA, indicating the presence of circulating autoantibodies.

E) Bilirubin:

Purpose: To assess for haemolysis.

Findings: Elevated **unconjugated bilirubin** due to the breakdown of haemoglobin.

F) Lactate Dehydrogenase (LDH):

Purpose: To measure the level of cell destruction.

Findings: Elevated LDH is a marker of red blood cell destruction.

G) Haptoglobin:

Purpose: To assess for intravascular haemolysis.

Findings: **Decreased haptoglobin** levels due to the binding of free haemoglobin released from lysed RBCs.

H) Cold Agglutinin Titre (for Cold AIHA):

Purpose: To measure the concentration of cold agglutinins (IgM antibodies).

Findings: Elevated titre supports the diagnosis of cold AIHA.

4. Explanation of Investigations

a) Direct Antiglobulin Test (DAT or Coombs' Test):

Procedure: A sample of the patient's blood is tested for antibodies or complement bound to red blood cells by adding anti-human globulin (Coombs reagent) to the blood. Agglutination of RBCs indicates a positive test.

Interpretation: A positive DAT confirms the presence of AIHA. The specific type of antibody (IgG or complement C3) can help differentiate between warm and cold AIHA.

5. Diagnostic Criteria for Autoimmune Haemolytic Anaemia

The diagnosis of AIHA is based on a combination of clinical findings, laboratory tests, and the exclusion of other causes of haemolysis. Diagnostic criteria include:

Anaemia: Presence of normocytic or macrocytic anaemia with signs of haemolysis.

Positive Direct Antiglobulin Test (DAT): Demonstrates the presence of IgG or complement C3 on RBCs.

Evidence of Haemolysis:

Elevated Bilirubin (unconjugated).

Elevated LDH.

Decreased Haptoglobin.

Exclusion of Other Causes of Haemolysis: Rule out conditions such as hereditary spherocytosis, G6PD deficiency, or drug-induced haemolysis.

6. First-Line Therapy According to Guidelines

The treatment of AIHA depends on the severity of anaemia, the type of AIHA (warm or cold), and the presence of any underlying conditions.

A) Treatment of Warm AIHA:

Corticosteroids:

First-line therapy for warm AIHA.

Dose: Prednisolone 1 mg/kg/day, tapered gradually over several weeks once haemolysis is controlled.

Mechanism: Suppresses the immune system and reduces the production of autoantibodies.

Rituximab (if steroids are ineffective):

Dose: 375 mg/m² once weekly for 4 weeks.

Mechanism: Targets CD20 on B-cells, reducing the production of autoantibodies.

Immunosuppressive Agents (if refractory):

Azathioprine or **cyclophosphamide**: Used in patients with chronic or refractory AIHA.

Mechanism: Further suppresses the immune response.

Splenectomy (rarely used):

Indication: Considered in patients with refractory warm AIHA who do not respond to medical treatment.

Mechanism: Removes the spleen, which is the primary site of RBC destruction in warm AIHA.

B) Treatment of Cold AIHA:

Avoid Cold Exposure:

First-line management for cold AIHA.

Mechanism: Prevents cold-induced haemolysis by avoiding exposure to cold temperatures.

Rituximab:

First-line pharmacological therapy for cold AIHA.

Dose: 375 mg/m² once weekly for 4 weeks.

Mechanism: Reduces the production of cold agglutinins (IgM antibodies).

Plasmapheresis (in severe cases):

Mechanism: Removes circulating autoantibodies from the blood.

Corticosteroids: Generally less effective in cold AIHA, but may be tried in certain cases.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Corticosteroids: Use with caution in patients with diabetes, osteoporosis, or infections due to the risk of worsening these conditions.

B) Second-Line Therapy:

Splenectomy (for warm AIHA refractory to medical therapy).

Rituximab: Used in patients who relapse after steroid treatment or for cold AIHA.

Immunosuppressive Therapy:

Azathioprine or **cyclophosphamide** in patients who do not respond to first-line therapies.

Mycophenolate mofetil as an alternative in refractory cases.

8. Routine Monitoring and Follow-Up

A) Full Blood Count (FBC):

Frequency: Every 1-2 weeks during active treatment, then every 3-6 months once stable.

Purpose: To monitor haemoglobin levels and reticulocyte count for response to therapy.

B) Direct Antiglobulin Test (DAT):

Frequency: Repeated if there is suspicion of relapse.

Purpose: To monitor for the return of autoantibodies on RBCs.

C) Liver Function Tests:

Purpose: To monitor bilirubin levels and assess the extent of haemolysis.

9. Complications of Autoimmune Haemolytic Anaemia

A) Thromboembolic Events:

Cause: AIHA is associated with an increased risk of venous thromboembolism due to intravascular haemolysis.

Management: Thromboprophylaxis may be considered in high-risk patients.

B) Infections:

Cause: Long-term corticosteroid use and immunosuppressive therapy increase the risk of infections.

Management: Prophylactic antibiotics or antiviral medications may be needed in immunosuppressed patients.

C) Chronic Anaemia:

Cause: Recurrent haemolysis can lead to chronic anaemia and fatigue.

Management: Long-term immunosuppressive therapy or splenectomy may be required for control.

Summary of Key Points for Autoimmune Haemolytic Anaemia (AIHA)

AIHA is caused by the immune system attacking and destroying red blood cells, leading to haemolysis and anaemia. It is classified as **warm AIHA** (IgG-mediated) or **cold AIHA** (IgM-mediated).

Diagnosis involves a positive **Direct Antiglobulin Test (DAT)** and evidence of haemolysis (elevated bilirubin, LDH, and reticulocyte count).

Treatment for **warm AIHA** includes **corticosteroids** and **rituximab**, while **cold AIHA** is managed with cold avoidance and rituximab.

Monitoring involves regular blood counts and assessing for complications such as thromboembolism and infections.

229. Sickle Cell Disease (SCD) and Haemolytic Anaemia

1. Detailed Definition of Sickle Cell Disease (SCD)

Sickle cell disease (SCD) is a group of inherited **haemoglobinopathies** characterised by the production of abnormal haemoglobin, known as **haemoglobin S (HbS)**. SCD leads to the formation of **sickle-shaped red blood cells** under conditions of low oxygen tension, dehydration, or acidosis. These sickled cells are rigid, prone to destruction (haemolysis), and can cause **vaso-occlusion**, leading to **painful crises** and **organ damage**.

SCD includes different genotypes, such as:

HbSS (Sickle Cell Anaemia): Homozygous for haemoglobin S, the most severe form.

HbSC: Heterozygous for haemoglobin S and haemoglobin C.

HbS/β-thalassemia: Combination of haemoglobin S and beta-thalassaemia, which can vary in severity.

The condition results in **chronic haemolytic anaemia** due to the shortened lifespan of sickled red blood cells and **intermittent vaso-occlusive crises**, which can lead to significant morbidity and mortality.

2. Common Presenting Complaints and Symptoms of Sickle Cell Disease

Patients with SCD experience a combination of chronic symptoms from haemolysis and acute events related to vaso-occlusion. Symptoms may vary depending on the severity of the disease and frequency of complications.

A) Symptoms of Chronic Haemolysis:

Fatigue and Weakness: Due to chronic anaemia.

Pallor: Particularly noticeable in mucous membranes.

Jaundice: Yellowing of the skin and eyes due to increased breakdown of haemoglobin.

Gallstones: Due to chronic haemolysis leading to the formation of **pigment stones** in the gallbladder.

B) Symptoms of Vaso-Occlusion (causing intermittent crises):

Painful Crises: Sudden episodes of severe pain, often in the back, chest, abdomen, or long bones (legs and arms). Triggered by dehydration, infection, or cold weather.

Acute Chest Syndrome (ACS): Chest pain, cough, difficulty breathing, fever, and hypoxia caused by vaso-occlusion in the lungs, which can be life-threatening.

Dactylitis: Painful swelling of the hands and feet, particularly in infants and young children, due to bone infarction.

Stroke: Sudden weakness, speech difficulties, or altered consciousness due to vaso-occlusion in cerebral vessels.

Priapism: Painful, prolonged erections due to sickling in penile vasculature.

C) Symptoms Related to Chronic Organ Damage:

Splenomegaly (in children) or **Autosplenectomy** (in adults): Due to repeated infarction of the spleen, leading to a non-functional spleen (autosplenectomy).

Renal Impairment: Proteinuria, haematuria, or chronic kidney disease due to sickling in the renal vasculature.

Delayed Growth and Puberty: Common in children with severe SCD due to chronic anaemia and nutritional deficits.

3. First-Line Investigations for Sickle Cell Disease

Several laboratory tests and imaging studies are necessary to confirm the diagnosis, monitor disease progression, and assess for complications in patients with SCD.

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels and red blood cell indices.

Findings:

Anaemia: Usually normocytic or macrocytic, with haemoglobin levels typically between 60-100 g/L.

Reticulocytosis: Elevated reticulocyte count due to increased bone marrow activity in response to haemolysis.

B) Peripheral Blood Smear:

Purpose: To examine the morphology of red blood cells.

Findings:

Sickle Cells: Crescent-shaped red blood cells, characteristic of SCD.

Target Cells: Common in SCD, especially in patients with co-existing thalassaemia.

Howell-Jolly Bodies: Nuclear remnants in red blood cells, indicating splenic dysfunction (autosplenectomy).

C) Haemoglobin Electrophoresis:

Purpose: To confirm the diagnosis by identifying the types of haemoglobin present.

Findings:

HbS: Present in all forms of SCD.

HbF (Fetal Haemoglobin): Often elevated in infants and may be increased in patients treated with **hydroxyurea**.

HbA: Absent in HbSS but may be present in small amounts in other genotypes (e.g., HbS/ β -thalassaemia).

D) Bilirubin:

Purpose: To assess for haemolysis.

Findings: Elevated **unconjugated bilirubin** due to increased breakdown of red blood cells.

E) Lactate Dehydrogenase (LDH):

Purpose: To measure cell destruction.

Findings: Elevated LDH is a marker of haemolysis.

F) Haptoglobin:

Purpose: To assess for intravascular haemolysis.

Findings: **Decreased haptoglobin** levels due to binding of free haemoglobin.

G) Imaging Studies:

Chest X-ray (if acute chest syndrome is suspected):

Purpose: To detect lung consolidation or atelectasis.

Findings: Infiltrates, typically in the lower lobes, indicating acute chest syndrome.

Transcranial Doppler Ultrasound (TCD) (for stroke prevention):

Purpose: To assess blood flow in cerebral arteries, especially in children.

Findings: Increased velocity suggests a higher risk of stroke due to vaso-occlusion.

4. Explanation of Investigations

a) Haemoglobin Electrophoresis:

Procedure: A blood sample is analysed to separate different types of haemoglobin based on their electrical charge and movement in an electric field.

Interpretation: The presence of HbS confirms sickle cell disease. Elevated levels of **HbF** (fetal haemoglobin) may be seen in infants or in patients treated with **hydroxyurea**, which increases HbF levels to reduce sickling.

5. Diagnostic Criteria for Sickle Cell Disease

The diagnosis of SCD is confirmed based on the following criteria:

Haemoglobin Electrophoresis: Detection of HbS, usually without HbA in patients with HbSS.

Peripheral Blood Smear: The presence of sickle cells and other abnormal red blood cell morphologies (e.g., Howell-Jolly bodies).

Family History: A known family history of sickle cell disease may be supportive.

Newborn Screening: In many countries, newborn screening programmes identify SCD at birth through genetic testing or electrophoresis.

6. First-Line Therapy According to Guidelines

The management of SCD focuses on preventing complications, treating acute crises, and managing chronic anaemia. **NICE guidelines** and other clinical protocols recommend a combination of pharmacological and supportive therapies.

A) Prevention and Management of Painful Crises:

Hydroxyurea:

First-line therapy to reduce the frequency of painful crises and acute chest syndrome.

Dose: 15-35 mg/kg/day.

Mechanism: Increases production of **fetal haemoglobin (HbF)**, which reduces red cell sickling and vaso-occlusion.

Outcome: Decreases the frequency of vaso-occlusive crises and improves overall quality of life.

Pain Management:

NSAIDs: For mild to moderate pain.

Opioids: For severe pain during vaso-occlusive crises (e.g., morphine or hydromorphone).

Fluids and Oxygen: Hydration and oxygen therapy to reduce sickling and improve tissue oxygenation.

B) Prevention of Infection:

Vaccination:

Pneumococcal Vaccination: Due to increased susceptibility to **Streptococcus pneumoniae** infection after splenic dysfunction.

Meningococcal and Haemophilus influenzae type B Vaccines: To reduce the risk of infection.

Prophylactic Penicillin:

Dose: 125 mg twice daily for children under 5 years, 250 mg twice daily for older children and adults.

Purpose: To reduce the risk of bacterial infections, especially in children with functional asplenia.

C) Blood Transfusions:

Chronic Transfusion Therapy:

Indication: Used in patients with a history of stroke or high-risk transcranial Doppler (TCD) velocities to prevent recurrent strokes.

Goal: Maintain HbS levels <30% to reduce vaso-occlusive events and organ damage.

Acute Transfusions:

Indication: For severe anaemia (e.g., during aplastic crisis or acute chest syndrome) or stroke.

Complications: Long-term transfusions may lead to **iron overload**, requiring iron chelation therapy (e.g., deferasirox or deferoxamine).

D) Management of Acute Chest Syndrome (ACS):

Antibiotics: Empirical broad-spectrum antibiotics (e.g., ceftriaxone and macrolides) to cover respiratory pathogens.

Bronchodilators: For wheezing or bronchospasm.

Blood Transfusion: To improve oxygenation and reduce sickling by lowering HbS levels.

Hydration and Oxygen Therapy: To support respiratory function and prevent further sickling.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Hydroxyurea: Avoid in pregnant women or those planning pregnancy, as it may have teratogenic effects. Close monitoring is also required in patients with bone marrow suppression.

B) Second-Line Therapy:

Chronic Red Blood Cell Exchange:

Indication: In patients with frequent complications (e.g., recurrent ACS or stroke) who are unresponsive to hydroxyurea or chronic transfusions.

Outcome: Reduces HbS levels and prevents complications of iron overload.

Bone Marrow Transplantation:

Indication: Considered curative in selected patients with severe SCD.

Outcome: Can potentially cure the disease by replacing the sickle-producing bone marrow with healthy donor cells.

8. Routine Monitoring and Follow-Up

A) Full Blood Count and Reticulocyte Count:

Frequency: Every 3-6 months to monitor anaemia, haemolysis, and bone marrow response.

Purpose: To assess the effectiveness of treatment (e.g., hydroxyurea or transfusions).

B) Serum Ferritin:

Frequency: Every 6-12 months in patients on chronic transfusions.

Purpose: To monitor for **iron overload**, which may require iron chelation therapy.

C) Transcranial Doppler (TCD) Ultrasound:

Frequency: Annually in children aged 2-16 years with SCD.

Purpose: To assess stroke risk by measuring blood flow velocity in cerebral arteries.

9. Complications of Sickle Cell Disease

A) Acute Chest Syndrome (ACS):

Cause: Vaso-occlusion in the pulmonary vasculature, leading to lung infarction and infection.

Management: Requires aggressive treatment with oxygen, fluids, transfusion, and antibiotics.

B) Stroke:

Cause: Vaso-occlusion in cerebral arteries, particularly in children with elevated TCD velocities.

Management: Chronic transfusions to reduce the risk of recurrence.

C) Iron Overload:

Cause: Chronic blood transfusions can lead to excess iron deposition in the liver, heart, and endocrine organs.

Management: Iron chelation therapy with **deferasirox** or **deferoxamine**.

D) Renal Impairment:

Cause: Sickle cell nephropathy due to chronic damage from sickling in the renal vasculature.

Management: Monitor renal function regularly, and treat with ACE inhibitors for proteinuria.

Summary of Key Points for Sickle Cell Disease

Sickle cell disease (SCD) is an inherited haemoglobinopathy characterised by chronic haemolytic anaemia and recurrent vaso-occlusive crises.

Diagnosis is confirmed with **haemoglobin electrophoresis** and the presence of sickle cells on a **peripheral blood smear**.

Management includes **hydroxyurea** to reduce painful crises, **blood transfusions** for stroke prevention, and supportive care to manage acute complications like **acute chest syndrome**.

Monitoring involves regular blood counts, ferritin levels (for iron overload), and transcranial Doppler (TCD) screening in children to assess stroke risk.

230. Thalassaemia and Haemolytic Anaemia

1. Detailed Definition of Thalassaemia

Thalassaemia is a group of inherited **haemoglobin disorders** caused by **defective production of globin chains**. This leads to **ineffective erythropoiesis** and **chronic haemolytic anaemia**. The condition is classified based on which globin chain is affected:

Alpha-thalassaemia: Reduced or absent production of **alpha-globin chains**, leading to excess beta-globin chains.

Beta-thalassaemia: Reduced or absent production of **beta-globin chains**, leading to excess alpha-globin chains.

Thalassaemia can present as either:

Thalassaemia major (Cooley's anaemia): Severe form requiring regular transfusions (typically seen in **beta-thalassaemia major**).

Thalassaemia intermedia: Milder form, may require occasional transfusions.

Thalassaemia minor (trait): Mild or asymptomatic, usually diagnosed incidentally, with minimal or no anaemia.

2. Common Presenting Complaints and Symptoms of Thalassaemia

The clinical presentation of thalassaemia depends on the severity of the condition. Patients with **thalassaemia major** often present in infancy or early childhood, while **thalassaemia minor** is often asymptomatic or presents with mild anaemia.

A) Thalassaemia Major:

Severe Anaemia: Usually detected in the first 6-12 months of life, leading to pallor, fatigue, and poor growth.

Failure to Thrive: Growth retardation and delayed developmental milestones due to chronic anaemia.

Jaundice: Yellowing of the skin and eyes due to increased haemolysis.

Splenomegaly: Enlarged spleen due to increased red cell destruction.

Bone Deformities: Characteristic **frontal bossing** and **maxillary overgrowth** (chipmunk facies) due to marrow hyperplasia from excessive red blood cell production.

Recurrent Infections: Due to splenomegaly or post-splenectomy.

B) Thalassaemia Intermedia:

Moderate Anaemia: Pallor, fatigue, and mild jaundice.

Splenomegaly: Less pronounced than in thalassaemia major but may still be present.

C) Thalassaemia Minor:

Mild Anaemia: Often asymptomatic or mild symptoms of fatigue or pallor. Usually identified incidentally during routine blood tests.

Normal Physical Examination: No splenomegaly or other significant clinical findings.

3. First-Line Investigations for Thalassaemia

Several laboratory tests are essential to confirm the diagnosis of thalassaemia, assess the severity, and monitor for complications.

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels, red blood cell count, and red cell indices.

Findings:

Microcytic, Hypochromic Anaemia: Low mean corpuscular volume (MCV) and mean corpuscular haemoglobin (MCH) due to the defective production of haemoglobin.

Elevated Red Cell Count: Despite anaemia, red blood cell count may be elevated due to ineffective erythropoiesis.

B) Blood Film:

Purpose: To examine red blood cell morphology.

Findings:

Target Cells: Red cells with a central area of haemoglobin, characteristic of thalassaemia.

Microcytosis and Hypochromia: Small, pale red cells typical of thalassaemia.

Basophilic Stippling: Seen in some cases, indicating abnormal red cell production.

C) Haemoglobin Electrophoresis:

Purpose: To identify abnormal haemoglobin variants and quantify haemoglobin levels.

Findings:

Beta-thalassaemia Major: Absent or reduced **HbA** (normal adult haemoglobin), increased **HbF** (fetal haemoglobin), and **HbA2**.

Beta-thalassaemia Minor: Increased **HbA2** and sometimes increased **HbF**.

Alpha-thalassaemia: Electrophoresis is typically normal or may show slightly increased HbA2 or HbF.

D) Genetic Testing:

Purpose: To confirm the specific mutation in the **HBB gene** (for beta-thalassaemia) or the **HBA genes** (for alpha-thalassaemia).

Findings: Identification of deletions or mutations in the alpha- or beta-globin genes, confirming the diagnosis.

E) Serum Ferritin and Iron Studies:

Purpose: To assess iron stores and rule out iron deficiency anaemia, which can mimic thalassaemia.

Findings:

Normal or Elevated Ferritin: Iron levels are typically normal or elevated due to increased absorption in response to chronic anaemia.

F) Bilirubin:

Purpose: To assess for haemolysis.

Findings: Elevated **unconjugated bilirubin** due to increased red blood cell breakdown.

4. Explanation of Investigations

a) Haemoglobin Electrophoresis:

Procedure: A blood sample is analysed to separate and quantify different types of haemoglobin.

Interpretation: Beta-thalassaemia is diagnosed by a reduction in HbA with an increase in **HbF** and **HbA2**. Alpha-thalassaemia typically shows normal results on electrophoresis and requires genetic testing for confirmation.

5. Diagnostic Criteria for Thalassaemia

The diagnosis of thalassaemia is based on a combination of clinical findings, blood tests, and genetic testing:

Microcytic, Hypochromic Anaemia: Low MCV and MCH on FBC, with or without significant symptoms.

Abnormal Haemoglobin Electrophoresis:

Beta-thalassaemia: Reduced or absent HbA, increased HbF and HbA2.

Alpha-thalassaemia: Normal or mildly altered results.

Genetic Testing: Identification of mutations or deletions in the HBB or HBA genes, confirming the type of thalassaemia.

6. First-Line Therapy According to Guidelines

The treatment of thalassaemia depends on the severity of the disease and focuses on managing anaemia, preventing complications, and improving quality of life. **NICE guidelines** and other clinical protocols recommend the following management strategies:

A) Thalassaemia Major:

Regular Blood Transfusions:

Frequency: Every 3-4 weeks to maintain haemoglobin levels above 90-100 g/L.

Outcome: Prevents complications of anaemia, such as poor growth, skeletal abnormalities, and heart failure.

Iron Chelation Therapy:

Indication: To prevent **iron overload**, which results from chronic transfusions.

Agents:

Deferasirox: Oral iron chelator.

Deferoxamine: Subcutaneous or intravenous iron chelator.

Outcome: Reduces iron deposition in organs such as the heart, liver, and pancreas, preventing complications like cardiomyopathy, cirrhosis, and diabetes.

Folic Acid Supplementation:

Dose: 1 mg/day.

Purpose: To support red blood cell production and prevent folate deficiency, which is common in chronic haemolysis.

Splenectomy (in certain cases):

Indication: For patients with hypersplenism causing severe anaemia or increased transfusion requirements.

Outcome: Reduces the need for frequent transfusions but increases the risk of infections.

Bone Marrow Transplantation (BMT):

Indication: Considered curative for thalassaemia major, particularly in younger patients with an HLA-matched sibling donor.

Outcome: Can eliminate the need for transfusions and chelation therapy in successful cases.

B) Thalassaemia Intermedia:

Blood Transfusions (as needed):

Indication: For patients with worsening anaemia or complications such as heart failure or pulmonary hypertension.

Outcome: Improves symptoms and prevents complications.

Iron Chelation Therapy:

Indication: For patients requiring intermittent transfusions who develop iron overload.

Hydroxyurea (in some cases):

Mechanism: Increases fetal haemoglobin (HbF) production, reducing the severity of anaemia.

Use: May be considered in some patients with thalassaemia intermedia.

C) Thalassaemia Minor:

No specific treatment is required for thalassaemia minor, as it is usually asymptomatic. Patients should be counselled on the genetic risk of passing the condition to offspring.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Splenectomy: Should be avoided unless absolutely necessary due to the increased risk of post-splenectomy infections (especially with encapsulated bacteria).

Iron Supplementation: Contraindicated in patients with thalassaemia unless there is clear evidence of iron deficiency, as these patients are prone to iron overload.

B) Second-Line Therapy:

Luspatercept (for transfusion-dependent thalassaemia):

Mechanism: Promotes erythroid maturation, reducing the need for blood transfusions.

Indication: Approved for use in patients with beta-thalassaemia who require regular transfusions.

Gene Therapy (experimental):

Mechanism: Involves introducing a functional beta-globin gene into the patient's hematopoietic stem cells.

Outcome: A promising future therapy that may reduce or eliminate the need for blood transfusions.

8. Routine Monitoring and Follow-Up

A) Full Blood Count (FBC):

Frequency: Every 3-6 months for patients with thalassaemia intermedia or minor, and more frequently for those requiring regular transfusions.

Purpose: To monitor haemoglobin levels and response to treatment.

B) Serum Ferritin:

Frequency: Every 3-6 months in transfusion-dependent patients.

Purpose: To monitor for iron overload and adjust chelation therapy as needed.

C) Liver Function Tests (LFTs):

Frequency: Every 6-12 months.

Purpose: To assess for iron-related liver damage.

D) Cardiac and Endocrine Monitoring:

Frequency: Annually, including echocardiography and endocrine assessments (e.g., glucose tolerance, thyroid function) to detect complications of iron overload.

9. Complications of Thalassaemia

A) Iron Overload:

Cause: Chronic transfusions lead to excess iron deposition in the heart, liver, and pancreas.

Management: Iron chelation therapy with deferasirox or deferoxamine.

B) Heart Failure:

Cause: Iron deposition in the myocardium leads to cardiomyopathy and heart failure.

Management: Regular monitoring with echocardiograms and aggressive iron chelation therapy.

C) Growth Retardation and Endocrine Disorders:

Cause: Chronic anaemia and iron overload can affect growth and cause hypogonadism, diabetes, and hypothyroidism.

Management: Endocrine evaluation and hormone replacement therapy as needed.

D) Bone Deformities:

Cause: Marrow expansion due to ineffective erythropoiesis.

Management: Blood transfusions to suppress bone marrow activity and prevent deformities.

Summary of Key Points for Thalassaemia

Thalassaemia is a genetic disorder characterised by defective production of haemoglobin, leading to chronic haemolytic anaemia and varying degrees of clinical severity.

Diagnosis is based on a **microcytic, hypochromic anaemia**, abnormal red blood cells on blood film, and **haemoglobin electrophoresis**.

Treatment for **thalassaemia major** includes regular **blood transfusions**, **iron chelation therapy**, and, in some cases, **bone marrow transplantation**.

Monitoring focuses on managing anaemia, preventing iron overload, and screening for complications such as cardiac and endocrine disorders.

231. Haemolytic Anaemia

1. Detailed Definition of Haemolytic Anaemia

Haemolytic anaemia refers to a condition where **red blood cells (RBCs)** are destroyed prematurely, leading to a shortage of circulating RBCs and consequent anaemia. The normal lifespan of an RBC is around 120 days, but in haemolytic anaemia, RBCs are destroyed faster than they can be produced by the bone marrow. The causes of haemolytic anaemia are diverse and can be classified into **intrinsic** (problems within the RBC) and **extrinsic** (external factors affecting the RBC) categories.

Types of Haemolytic Anaemia:

Intrinsic (Inherited): Defects within the red blood cells themselves, such as **hereditary spherocytosis**, **G6PD deficiency**, **sickle cell disease**, and **thalassaemia**.

Extrinsic (Acquired): External factors that lead to RBC destruction, including **autoimmune haemolytic anaemia (AIHA)**, **mechanical destruction** (e.g., prosthetic heart valves), **infections** (e.g., malaria), and **drug-induced haemolysis**.

2. Common Presenting Complaints and Symptoms of Haemolytic Anaemia

Symptoms of haemolytic anaemia vary depending on the severity and speed of onset but are typically related to both **anaemia** and **haemolysis**.

A) Symptoms of Anaemia:

Fatigue: General tiredness and reduced exercise tolerance.

Pallor: Pale skin, particularly noticeable in the mucous membranes (e.g., inside the mouth).

Shortness of Breath: Exertional dyspnoea due to reduced oxygen-carrying capacity.

Tachycardia: Increased heart rate as a compensatory response to low oxygen levels.

B) Symptoms of Haemolysis:

Jaundice: Yellowing of the skin and eyes due to elevated bilirubin levels from the breakdown of haemoglobin.

Dark Urine: Haemoglobinuria, particularly in cases of intravascular haemolysis.

Splenomegaly: Enlargement of the spleen due to increased destruction of RBCs.

Gallstones: Chronic haemolysis may lead to the formation of **pigment gallstones**.

C) Additional Symptoms in Specific Causes:

Painful Crises: In sickle cell disease, patients may present with painful episodes due to vaso-occlusion.

Cold-Induced Symptoms: In cold agglutinin disease (a type of autoimmune haemolytic anaemia), symptoms like **acrocyanosis** and **Raynaud's phenomenon** may be triggered by cold exposure.

3. First-Line Investigations for Haemolytic Anaemia

The diagnosis of haemolytic anaemia requires a combination of blood tests to assess anaemia, identify haemolysis, and investigate the underlying cause.

A) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels, RBC count, and reticulocyte count.

Findings:

Anaemia: Reduced haemoglobin levels, with normocytic or macrocytic red blood cells depending on the cause.

Reticulocytosis: Elevated reticulocyte count due to increased bone marrow response to anaemia.

B) Blood Film:

Purpose: To examine the morphology of red blood cells.

Findings:

Spherocytes: Seen in hereditary spherocytosis and autoimmune haemolytic anaemia (AIHA).

Sickle Cells: Seen in sickle cell disease.

Schistocytes: Fragmented red cells seen in **mechanical haemolysis** (e.g., from heart valves or disseminated intravascular coagulation [DIC]).

C) Bilirubin:

Purpose: To assess for haemolysis.

Findings: Elevated **unconjugated bilirubin** due to the increased breakdown of RBCs.

D) Lactate Dehydrogenase (LDH):

Purpose: To measure the extent of cell destruction.

Findings: Elevated LDH is a marker of increased red blood cell destruction.

E) Haptoglobin:

Purpose: To assess for intravascular haemolysis.

Findings: **Decreased haptoglobin** levels, as haptoglobin binds free haemoglobin from lysed red blood cells.

F) Direct Antiglobulin Test (DAT or Coombs' Test):

Purpose: To detect antibodies or complement bound to the surface of red blood cells.

Findings:

Positive DAT: Confirms autoimmune haemolytic anaemia, detecting either IgG antibodies or complement on red blood cells.

G) Haemoglobin Electrophoresis (if inherited haemoglobinopathy is suspected):

Purpose: To detect abnormal types of haemoglobin.

Findings: Abnormal haemoglobin (e.g., HbS in sickle cell disease, or reduced HbA in thalassaemia).

4. Explanation of Investigations

a) Direct Antiglobulin Test (DAT or Coombs' Test):

Procedure: A blood sample is taken and exposed to anti-human antibodies (Coombs reagent) to detect if antibodies or complement proteins are bound to RBCs.

Interpretation: A positive DAT indicates immune-mediated destruction of RBCs, confirming autoimmune haemolytic anaemia.

5. Diagnostic Criteria for Haemolytic Anaemia

The diagnosis of haemolytic anaemia is based on evidence of haemolysis, anaemia, and identification of the underlying cause. The criteria include:

Anaemia: Low haemoglobin with signs of haemolysis (jaundice, dark urine, splenomegaly).

Reticulocytosis: Elevated reticulocyte count due to increased RBC production in response to haemolysis.

Markers of Haemolysis:

Elevated Bilirubin (unconjugated).

Elevated LDH.

Decreased Haptoglobin.

Positive DAT (for autoimmune haemolytic anaemia).

Abnormal Red Cell Morphology: On blood film, such as spherocytes, schistocytes, or sickle cells.

6. First-Line Therapy According to Guidelines

The treatment of haemolytic anaemia depends on the underlying cause and severity of the condition. **NICE guidelines** and other expert recommendations guide treatment.

A) Autoimmune Haemolytic Anaemia (AIHA):

Corticosteroids:

First-line therapy for warm AIHA.

Dose: Prednisolone 1 mg/kg/day, tapered based on response.

Mechanism: Suppresses the immune system to reduce antibody production and haemolysis.

Rituximab (if corticosteroids are ineffective):

Mechanism: Monoclonal antibody targeting CD20 on B-cells, reducing autoantibody production.

Splenectomy (for refractory cases):

Mechanism: Removes the spleen, which is responsible for the destruction of antibody-coated red blood cells.

B) Sickle Cell Disease:

Hydroxyurea:

Dose: 15-35 mg/kg/day.

Mechanism: Increases production of fetal haemoglobin (HbF), which reduces sickling of RBCs.

Blood Transfusions (for severe anaemia or acute complications like stroke).

Pain Management:

NSAIDs and opioids during vaso-occlusive crises.

C) Hereditary Spherocytosis:

Splenectomy:

Indication: Considered in severe cases with recurrent haemolysis or significant splenomegaly.

Folic Acid Supplementation:

Dose: 1 mg/day to support increased red blood cell production.

D) G6PD Deficiency:

Avoid Triggers:

Avoid oxidative stressors such as certain drugs (e.g., sulfonamides, antimalarials), infections, and fava beans.

Supportive Care:

Blood transfusions may be needed in severe cases of haemolysis.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Corticosteroids: Use cautiously in patients with infections, diabetes, or osteoporosis due to potential exacerbation of these conditions.

Splenectomy: Should be avoided unless absolutely necessary due to the increased risk of infections post-splenectomy.

B) Second-Line Therapy:

Immunosuppressive Agents:

Azathioprine or **cyclophosphamide** for autoimmune haemolytic anaemia unresponsive to steroids and rituximab.

Bone Marrow Transplantation:

For severe hereditary haemolytic anaemias (e.g., sickle cell disease or thalassaemia) that are refractory to standard treatments.

8. Routine Monitoring and Follow-Up

A) Full Blood Count and Reticulocyte Count:

Frequency: Every 3-6 months or more frequently during active haemolysis.

Purpose: To monitor anaemia and response to treatment.

B) Liver Function Tests (Bilirubin):

Purpose: To assess for ongoing haemolysis and monitor liver function.

C) Direct Antiglobulin Test (DAT):

Frequency: Repeated in autoimmune haemolytic anaemia if there is a concern for relapse.

9. Complications of Haemolytic Anaemia

A) Gallstones:

Cause: Chronic haemolysis increases bilirubin production, leading to the formation of pigment gallstones.

Management: Cholecystectomy may be required in symptomatic cases.

B) Splenomegaly and Hypersplenism:

Cause: Chronic haemolysis causes splenic enlargement and increased destruction of blood cells.

Management: Splenectomy may be considered if hypersplenism causes pancytopenia.

C) Iron Overload:

Cause: Recurrent blood transfusions can lead to iron deposition in organs.

Management: Iron chelation therapy (e.g., deferasirox or deferoxamine) is required to prevent organ damage.

Summary of Key Points for Haemolytic Anaemia

Haemolytic anaemia results from the premature destruction of red blood cells, leading to anaemia and elevated markers of haemolysis.

Diagnosis involves evidence of haemolysis (reticulocytosis, elevated bilirubin, LDH, decreased haptoglobin) and identification of the underlying cause (e.g., positive DAT in autoimmune haemolytic anaemia).

Treatment is tailored to the underlying cause, with **steroids** and **rituximab** for autoimmune haemolytic anaemia, **hydroxyurea** for sickle cell disease, and **splenectomy** in hereditary spherocytosis.

Monitoring involves regular blood tests to assess for anaemia and haemolysis, and vigilance for complications such as **gallstones**, **splenomegaly**, and **iron overload**.

232. Haemolytic Disease of the Newborn (HDN)

1. Detailed Definition of Haemolytic Disease of the Newborn (HDN)

Haemolytic disease of the newborn (HDN), also known as **erythroblastosis fetalis**, is a condition that occurs when the **maternal immune system** produces antibodies against the red blood cells (RBCs) of the fetus. This leads to **immune-mediated haemolysis** of fetal RBCs,

resulting in **anaemia**, **jaundice**, and, in severe cases, **hydrops fetalis** (fetal heart failure with fluid accumulation).

HDN typically occurs when there is an **incompatibility** between the blood group of the mother and the fetus, most commonly related to **Rhesus (Rh) incompatibility**. The most common forms are:

RhD incompatibility: Occurs when an **RhD-negative** mother carries an **RhD-positive** fetus. The mother's immune system may produce anti-D antibodies that attack the fetus's RhD-positive red blood cells.

ABO incompatibility: Occurs when the mother has blood group O and the fetus has blood group A, B, or AB, leading to the production of antibodies (anti-A or anti-B) that attack the fetal RBCs.

2. Common Presenting Complaints and Symptoms of HDN

The severity of symptoms depends on the degree of haemolysis and the timing of onset. In some cases, HDN presents before birth, while in others, symptoms appear after delivery.

A) Prenatal Symptoms (identified via ultrasound or maternal testing):

Hydrops Fetalis: Severe anaemia leads to fetal heart failure and fluid accumulation in tissues, manifesting as skin oedema, pleural effusion, pericardial effusion, and ascites.

Fetal Anaemia: May present as fetal distress, detected by abnormal fetal heart rate or decreased fetal movements.

Hepatosplenomegaly: Due to increased erythropoiesis in the liver and spleen in response to anaemia.

B) Postnatal Symptoms:

Jaundice: Yellowing of the skin and eyes due to elevated **unconjugated bilirubin** levels from RBC destruction. Typically appears within the first 24 hours of life.

Anaemia: Pale skin, lethargy, and tachycardia due to a reduced number of circulating RBCs.

Hepatosplenomegaly: Enlargement of the liver and spleen due to increased RBC destruction and production.

Kernicterus: Neurological damage caused by high levels of **unconjugated bilirubin** crossing the blood-brain barrier, potentially leading to seizures, lethargy, or long-term motor and cognitive impairment.

3. First-Line Investigations for Haemolytic Disease of the Newborn

Several laboratory and imaging studies are required to assess haemolysis, detect maternal-fetal blood incompatibility, and monitor the severity of anaemia and hyperbilirubinaemia.

A) Maternal Antibody Screening:

Purpose: To detect maternal antibodies that may target fetal red blood cells.

Findings: A positive **indirect antiglobulin test (IAT)** or **indirect Coombs' test** confirms the presence of antibodies in maternal blood, such as **anti-D** in RhD incompatibility.

B) Fetal Ultrasound (Prenatal):

Purpose: To assess for signs of **hydrops fetalis** and fetal distress.

Findings: Ascites, pleural effusion, pericardial effusion, or skin oedema, which are indicative of hydrops fetalis.

C) Fetal Blood Sampling (Cordocentesis):

Purpose: To directly measure fetal haemoglobin levels, assess the degree of anaemia, and guide management.

Findings: Low fetal haemoglobin indicates severe anaemia requiring intervention.

D) Full Blood Count (FBC) and Reticulocyte Count (Postnatal):

Purpose: To assess the degree of anaemia and red blood cell production in the newborn.

Findings:

Anaemia: Reduced haemoglobin levels.

Reticulocytosis: Elevated reticulocyte count due to increased bone marrow response to haemolysis.

E) Direct Antiglobulin Test (DAT or Direct Coombs' Test) (Postnatal):

Purpose: To detect antibodies bound to the surface of the newborn's RBCs.

Findings: A **positive DAT** confirms antibody-mediated haemolysis, typically seen in Rh or ABO incompatibility.

F) Bilirubin Levels (Postnatal):

Purpose: To assess the degree of hyperbilirubinaemia and risk of kernicterus.

Findings: Elevated **unconjugated bilirubin** levels due to RBC breakdown.

4. Explanation of Investigations

a) Direct Antiglobulin Test (DAT):

Procedure: A sample of the newborn's blood is mixed with Coombs reagent, which binds to antibodies or complement attached to RBCs.

Interpretation: A **positive DAT** indicates that maternal antibodies are present on the surface of the newborn's RBCs, confirming immune-mediated haemolysis.

5. Diagnostic Criteria for Haemolytic Disease of the Newborn

The diagnosis of HDN is confirmed by the presence of the following criteria:

Maternal-Fetal Blood Group Incompatibility:

RhD incompatibility (mother RhD-negative, fetus RhD-positive) or ABO incompatibility (mother O, fetus A, B, or AB).

Positive Direct Antiglobulin Test (DAT): Confirms the presence of maternal antibodies bound to the newborn's red blood cells.

Evidence of Haemolysis:

Anaemia: Low haemoglobin levels.

Reticulocytosis: Elevated reticulocyte count.

Hyperbilirubinaemia: Elevated unconjugated bilirubin.

Exclusion of Other Causes: Rule out non-immune causes of neonatal jaundice and anaemia.

6. First-Line Therapy According to Guidelines

Management of HDN depends on the severity of anaemia and hyperbilirubinaemia, with an emphasis on preventing complications such as kernicterus and heart failure. **NICE guidelines** and other clinical protocols recommend the following treatments:

A) Prenatal Management (in severe cases):**Intrauterine Transfusion (IUT):**

Indication: For fetuses with severe anaemia (e.g., haemoglobin <10 g/dL) detected via cordocentesis or ultrasound signs of hydrops.

Procedure: Transfusion of compatible blood directly into the fetal circulation.

Outcome: Corrects fetal anaemia and prolongs pregnancy, reducing the risk of hydrops and intrauterine death.

Early Delivery:

Indication: Considered in cases where severe anaemia or hydrops fetalis persists despite intrauterine transfusions.

Outcome: Allows postnatal treatment to be initiated.

B) Postnatal Management:**Phototherapy:**

Indication: For newborns with elevated bilirubin levels to prevent kernicterus.

Mechanism: Blue light converts unconjugated bilirubin into water-soluble isomers that can be excreted without needing conjugation by the liver.

Outcome: Reduces bilirubin levels and prevents neurological complications.

Exchange Transfusion:

Indication: For severe hyperbilirubinaemia or ongoing haemolysis unresponsive to phototherapy.

Procedure: Replaces the newborn's blood with compatible donor blood to rapidly reduce bilirubin and remove circulating antibodies.

Outcome: Corrects anaemia and hyperbilirubinaemia, reducing the risk of kernicterus.

Intravenous Immunoglobulin (IVIG):

Indication: To reduce haemolysis in cases of significant antibody-mediated haemolysis.

Mechanism: IVIG blocks Fc receptors on macrophages, reducing antibody-mediated destruction of RBCs.

Dose: 0.5-1 g/kg, repeated if necessary.

Outcome: Reduces the need for exchange transfusion and lowers the risk of severe haemolysis.

Blood Transfusion:

Indication: For newborns with severe anaemia.

Outcome: Corrects anaemia and improves oxygen delivery to tissues.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Phototherapy: Should be used cautiously in infants with **bronze baby syndrome**, a rare condition in cholestatic jaundiced infants where bilirubin builds up in the skin.

B) Second-Line Therapy:

Repeated Exchange Transfusions:

Indication: For ongoing haemolysis and hyperbilirubinaemia that do not respond to the initial treatment.

Long-Term Transfusions (for anaemia):

Indication: In severe cases of prolonged haemolysis where the newborn develops chronic anaemia requiring repeated transfusions.

8. Routine Monitoring and Follow-Up

A) Bilirubin Levels:

Frequency: Monitored every 4-6 hours during phototherapy and after exchange transfusion to assess treatment efficacy and prevent rebound hyperbilirubinaemia.

Target: Keep bilirubin below the levels associated with kernicterus based on age and risk factors.

B) Haemoglobin Levels:

Frequency: Monitored daily in the first few days of life and less frequently thereafter.

Purpose: To assess for the resolution of anaemia and monitor for delayed anaemia after treatment.

C) Neurological Monitoring:

Purpose: To assess for signs of kernicterus (e.g., lethargy, hypotonia, poor feeding, seizures) and monitor long-term neurodevelopment in affected infants.

9. Complications of Haemolytic Disease of the Newborn

A) Kernicterus:

Cause: Excessive **unconjugated bilirubin** crosses the blood-brain barrier and deposits in the basal ganglia.

Symptoms: Lethargy, hypotonia, poor feeding, high-pitched crying, seizures, and long-term developmental delays.

Management: Requires urgent phototherapy or exchange transfusion to prevent permanent neurological damage.

B) Hydrops Fetalis:

Cause: Severe fetal anaemia leading to heart failure and fluid accumulation in fetal tissues.

Management: Intrauterine transfusions and early delivery if detected prenatally.

C) Delayed Anaemia:

Cause: Persistence of maternal antibodies in the newborn's circulation can cause delayed haemolysis, leading to anaemia after the initial postnatal period.

Management: May require blood transfusions in the weeks following birth.

Summary of Key Points for Haemolytic Disease of the Newborn (HDN)

Haemolytic disease of the newborn (HDN) results from **maternal antibodies** crossing the placenta and attacking fetal red blood cells, leading to haemolysis, anaemia, and hyperbilirubinaemia.

Diagnosis is confirmed with **blood group testing**, **maternal antibody screening**, and a **positive direct antiglobulin test (DAT)** in the newborn.

Management includes **phototherapy**, **exchange transfusions**, and **intravenous immunoglobulin (IVIG)** to prevent complications such as **kernicterus** and **hydrops fetalis**.

Monitoring involves frequent assessment of **bilirubin** and **haemoglobin** levels to guide treatment and prevent long-term complications.

233. Haemophilia

1. Detailed Definition of Haemophilia

Haemophilia is an inherited **bleeding disorder** characterised by **deficient or defective clotting factors**, leading to an inability to form proper blood clots and resulting in prolonged bleeding episodes. There are two major types of haemophilia:

Haemophilia A: Caused by a deficiency of **factor VIII**.

Haemophilia B (also known as **Christmas disease**): Caused by a deficiency of **factor IX**.

Haemophilia is an **X-linked recessive disorder**, meaning it primarily affects males, while females can be carriers. Severity is classified based on the level of clotting factor activity:

Severe: <1% factor activity.

Moderate: 1-5% factor activity.

Mild: 5-40% factor activity.

2. Common Presenting Complaints and Symptoms of Haemophilia

The hallmark of haemophilia is **prolonged bleeding**, which can occur spontaneously or after trauma, surgery, or injury. The severity of symptoms depends on the degree of clotting factor deficiency.

A) Common Bleeding Manifestations:

Haemarthrosis (bleeding into joints): Most common presentation in severe haemophilia. Patients may present with:

Joint Swelling: Particularly in the knees, elbows, and ankles.

Pain and Stiffness: Due to recurrent bleeding into the joints, leading to inflammation and degeneration of the joint (haemophilic arthropathy).

Muscle Haematomas: Large, painful collections of blood within muscles, which can compress nerves and blood vessels.

Prolonged Bleeding After Injury or Surgery: Even minor trauma can cause excessive and prolonged bleeding.

Mucosal Bleeding: Epistaxis (nosebleeds), gum bleeding, and prolonged bleeding after tooth extractions are common.

Haematuria: Blood in the urine can occur in some patients.

B) Life-Threatening Bleeding:

Intracranial Haemorrhage: Spontaneous or trauma-induced bleeding within the brain, a major cause of morbidity and mortality in haemophilia.

Gastrointestinal Bleeding: Blood in stools or vomit.

Retroperitoneal Bleeding: Bleeding into the abdominal cavity, which can cause abdominal pain and lead to shock.

3. First-Line Investigations for Haemophilia

The diagnosis of haemophilia is based on a combination of **clotting tests** and **factor assays** to identify and quantify the specific clotting factor deficiency.

A) Activated Partial Thromboplastin Time (aPTT):

Purpose: To assess the intrinsic pathway of the clotting cascade.

Findings: **Prolonged aPTT** in haemophilia A and B due to factor VIII or IX deficiency. The **prothrombin time (PT)** is typically normal.

B) Factor VIII and Factor IX Assays:

Purpose: To measure the levels of factor VIII (for haemophilia A) and factor IX (for haemophilia B).

Findings:

Low Factor VIII Activity: Confirms haemophilia A.

Low Factor IX Activity: Confirms haemophilia B.

The severity of haemophilia is determined based on the percentage of clotting factor activity:

Severe: <1% activity.

Moderate: 1-5% activity.

Mild: 5-40% activity.

C) Genetic Testing:

Purpose: To identify mutations in the **F8 gene** (factor VIII deficiency) or **F9 gene** (factor IX deficiency).

Findings: Confirm the genetic mutation responsible for haemophilia. This is particularly important for carrier detection in female relatives.

D) Bleeding Time and Platelet Count:

Purpose: To assess for other causes of bleeding.

Findings: Bleeding time and platelet count are typically **normal** in haemophilia, as it is a coagulation factor deficiency, not a platelet disorder.

4. Explanation of Investigations

a) Factor VIII/IX Assays:

Procedure: A blood sample is taken to measure the activity of factor VIII or factor IX. The activity is measured as a percentage of the normal factor level.

Interpretation: Low factor VIII or IX activity confirms the diagnosis of haemophilia A or B, respectively.

5. Diagnostic Criteria for Haemophilia

The diagnosis of haemophilia is based on the following criteria:

Prolonged aPTT: Indicates a deficiency in the intrinsic clotting pathway.

Low Factor VIII or Factor IX Levels: Factor VIII deficiency confirms haemophilia A, while factor IX deficiency confirms haemophilia B.

Family History: A family history of bleeding disorders supports the diagnosis, although spontaneous mutations can occur in 30% of cases.

Genetic Testing: Can be used to confirm the specific mutation in the **F8** or **F9** gene.

6. First-Line Therapy According to Guidelines

The treatment of haemophilia involves **replacement therapy** with the deficient clotting factor to prevent and control bleeding episodes. **NICE guidelines** recommend a **prophylactic** or **on-demand** approach depending on the severity of haemophilia.

A) Factor Replacement Therapy:

Factor VIII Concentrate (for Haemophilia A):

Dose: 25-50 IU/kg depending on the severity of the bleed and body weight.

Mechanism: Replaces the missing factor VIII, allowing normal clot formation.

Frequency: Can be given **on-demand** for bleeding episodes or **prophylactically** in severe haemophilia to prevent spontaneous bleeds.

Factor IX Concentrate (for Haemophilia B):

Dose: 30-50 IU/kg depending on the severity of the bleed.

Mechanism: Replaces the missing factor IX, promoting normal clotting.

Extended Half-Life Factor Products:

Newer clotting factor concentrates that last longer in the bloodstream, reducing the frequency of infusions, particularly for prophylaxis.

B) Desmopressin (DDAVP):

Indication: Used in **mild haemophilia A** to temporarily increase factor VIII levels by releasing stored factor VIII from endothelial cells.

Dose: 0.3 mcg/kg intravenously or subcutaneously.

Mechanism: Stimulates the release of factor VIII and von Willebrand factor.

Outcome: Useful for minor procedures or mild bleeding episodes in patients with mild haemophilia A.

C) Antifibrinolytics (e.g., Tranexamic Acid):

Indication: To prevent or reduce bleeding, particularly after dental procedures or surgery.

Dose: 10-15 mg/kg, given orally or intravenously.

Mechanism: Inhibits fibrinolysis (breakdown of clots), helping to stabilise clots.

Outcome: Can be used alongside factor replacement therapy.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Desmopressin: Should be avoided in patients with severe haemophilia A or haemophilia B, as it does not increase factor IX levels. It is also contraindicated in patients with a history of cardiovascular disease or hyponatraemia due to the risk of fluid retention.

B) Second-Line Therapy:

Bypassing Agents (for patients with inhibitors):

Recombinant Factor VIIa or Activated Prothrombin Complex Concentrates (aPCC):

Indication: For patients who develop inhibitors (antibodies) to factor VIII or IX.

Mechanism: Bypass the need for factor VIII or IX by promoting clot formation through alternative pathways.

Emicizumab (for Haemophilia A):

Mechanism: A bispecific monoclonal antibody that mimics the function of factor VIII, allowing clot formation in patients with haemophilia A.

Use: Particularly useful in patients with inhibitors to factor VIII.

8. Routine Monitoring and Follow-Up

A) Factor Levels:

Frequency: Regular monitoring during prophylaxis or after treatment for bleeding episodes to ensure adequate factor levels.

Purpose: To adjust dosing and ensure effective management of bleeding risk.

B) Joint Monitoring:

Purpose: To assess for early signs of **haemophilic arthropathy** (joint damage) due to repeated joint bleeds. This may include physical examinations, joint ultrasounds, or MRIs.

C) Inhibitor Testing:

Frequency: Periodic testing for **inhibitors** (antibodies) against factor VIII or IX, especially in patients on regular factor replacement therapy.

Purpose: To detect and manage the development of inhibitors, which reduce the effectiveness of replacement therapy.

9. Complications of Haemophilia

A) Joint Damage (Haemophilic Arthropathy):

Cause: Recurrent haemarthrosis leads to chronic inflammation, joint damage, and deformity.

Management: Regular prophylactic factor replacement to prevent bleeds and early intervention with physiotherapy.

B) Inhibitor Development:

Cause: Some patients, particularly those with severe haemophilia, may develop **inhibitors** (antibodies) against factor VIII or IX, making replacement therapy ineffective.

Management: Requires the use of **bypassing agents** or **immune tolerance therapy** to eliminate the inhibitor.

C) Intracranial Haemorrhage:

Cause: Spontaneous or trauma-induced bleeding in the brain is a life-threatening complication.

Management: Immediate factor replacement and neurosurgical intervention if needed.

Summary of Key Points for Haemophilia

Haemophilia is a genetic bleeding disorder caused by a deficiency in **factor VIII** (haemophilia A) or **factor IX** (haemophilia B), leading to prolonged bleeding.

Diagnosis is confirmed by prolonged **aPTT** and low factor VIII or IX levels, with genetic testing to confirm the specific mutation.

Management involves **factor replacement therapy** (on-demand or prophylactic) to prevent and control bleeding episodes. **Desmopressin** may be used in mild haemophilia A.

Monitoring includes regular assessment of factor levels, joint health, and inhibitor development, with attention to preventing complications such as **haemophilic arthropathy** and **intracranial haemorrhage**.

234. Haemorrhagic Disease of the Newborn (Vitamin K Deficiency Bleeding - VKDB)

1. Detailed Definition of Haemorrhagic Disease of the Newborn

Haemorrhagic Disease of the Newborn (HDN), now referred to as **Vitamin K Deficiency Bleeding (VKDB)**, is a bleeding disorder that occurs in newborns due to insufficient levels of **vitamin K**. Vitamin K is essential for the synthesis of **clotting factors II, VII, IX, and X**. Newborns have naturally low levels of vitamin K because of limited placental transfer, low levels in breast milk, and immature liver function. Without adequate vitamin K, the clotting factors remain inactive, leading to an increased risk of bleeding.

VKDB can be classified into three types based on the timing of presentation:

Early VKDB: Occurs within the first 24 hours of life, typically in infants of mothers on medications such as anticonvulsants or antibiotics.

Classic VKDB: Occurs between 2 to 7 days after birth and is the most common type, particularly in exclusively breastfed infants.

Late VKDB: Occurs between 2 weeks and 6 months of life, mainly in breastfed infants who did not receive prophylactic vitamin K at birth.

2. Common Presenting Complaints and Symptoms of VKDB

The symptoms of VKDB depend on the severity of the bleeding and when it occurs. Bleeding can be spontaneous or result from minor trauma or procedures.

A) Classic VKDB (2-7 days):

Gastrointestinal Bleeding: Blood-stained vomit or black tarry stools (melaena).

Umbilical Bleeding: Persistent bleeding from the umbilical stump.

Cutaneous Bleeding: Bruising or purpura, particularly around the head and face after delivery.

Epistaxis: Nosebleeds.

Prolonged Bleeding After Procedures: Bleeding following circumcision or venipuncture.

B) Late VKDB (2 weeks to 6 months):

Intracranial Haemorrhage: Presenting with signs of increased intracranial pressure such as lethargy, irritability, vomiting, seizures, or bulging fontanelle. This is the most severe and life-threatening presentation.

Gastrointestinal or Mucosal Bleeding: Continued or recurrent bleeding from the gastrointestinal tract or mucous membranes.

Ecchymosis: Large bruises over the body.

C) Early VKDB (<24 hours):

Severe Bleeding: Early onset bleeding due to maternal medications (e.g., anticonvulsants, warfarin) affecting the fetus, leading to severe, life-threatening bleeding, such as intracranial or intra-abdominal haemorrhage.

3. First-Line Investigations for VKDB

The diagnosis of VKDB is clinical, supported by coagulation studies indicating vitamin K deficiency and its impact on clotting factor synthesis.

A) Coagulation Studies:

Prothrombin Time (PT):

Purpose: To assess the extrinsic and common pathways of the clotting cascade.

Findings: **Prolonged PT** due to decreased levels of vitamin K-dependent clotting factors (II, VII, IX, and X).

Activated Partial Thromboplastin Time (aPTT):

Purpose: To assess the intrinsic and common pathways of the clotting cascade.

Findings: aPTT may be **prolonged**, though this is less sensitive than PT in detecting vitamin K deficiency.

B) Platelet Count:

Purpose: To exclude thrombocytopenia as a cause of bleeding.

Findings: **Normal platelet count** is typical in VKDB, indicating that bleeding is due to clotting factor deficiency rather than platelet abnormalities.

C) Clotting Factor Assays:

Purpose: To directly measure the levels of vitamin K-dependent clotting factors (II, VII, IX, and X).

Findings: **Low levels** of these clotting factors confirm vitamin K deficiency.

D) Imaging Studies:

Cranial Ultrasound or CT Scan (if intracranial haemorrhage is suspected):

Purpose: To assess for the presence of bleeding in the brain.

Findings: May reveal **intracranial haemorrhage**, which is a serious complication of late VKDB.

4. Explanation of Investigations

a) Prothrombin Time (PT):

Procedure: A blood sample is tested to measure how long it takes for blood to clot by evaluating the function of the extrinsic and common clotting pathways.

Interpretation: A prolonged PT in the context of normal platelet count and a history of insufficient vitamin K prophylaxis suggests VKDB.

5. Diagnostic Criteria for VKDB

The diagnosis of VKDB is made based on clinical presentation, coagulation studies, and response to vitamin K administration. The following criteria are used:

Prolonged PT: Reflecting the deficiency of vitamin K-dependent clotting factors.

Normal Platelet Count: To rule out other causes of bleeding such as thrombocytopenia.

Response to Vitamin K: Bleeding and coagulation abnormalities rapidly improve after the administration of vitamin K.

History: The absence of vitamin K prophylaxis or risk factors (e.g., exclusive breastfeeding, maternal medications affecting vitamin K metabolism).

6. First-Line Therapy According to Guidelines

NICE guidelines recommend that all newborns receive prophylactic **vitamin K** to prevent VKDB. In cases where VKDB develops, immediate treatment is required to correct clotting abnormalities and stop bleeding.

A) Vitamin K Administration:

Vitamin K Prophylaxis (prevention):

Indication: Given to all newborns shortly after birth to prevent VKDB.

Dose:

Intramuscular (IM): 1 mg given as a single dose at birth (preferred method).

Oral: 2 mg at birth, followed by further doses at 7 days and 1 month (less effective than IM).

Outcome: Significantly reduces the risk of both early and late VKDB.

Vitamin K Therapy (for treatment of VKDB):

Dose: 1-5 mg intravenously (IV) or intramuscularly (IM).

Mechanism: Replenishes the body's vitamin K stores, allowing for the synthesis of clotting factors.

Outcome: Rapid correction of coagulation abnormalities, with improvement in PT and resolution of bleeding within hours.

B) Fresh Frozen Plasma (FFP):

Indication: For severe bleeding or in cases where immediate correction of clotting factors is needed (e.g., intracranial haemorrhage).

Dose: 10-20 mL/kg.

Mechanism: Provides clotting factors II, VII, IX, and X to support coagulation.

Outcome: Immediate, temporary correction of clotting deficiencies until vitamin K takes effect.

C) Blood Transfusion:

Indication: For severe anaemia or haemodynamic instability due to blood loss.

Outcome: Restores circulating blood volume and oxygen-carrying capacity.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Oral Vitamin K in Severe Bleeding: Oral vitamin K is not effective for acute, severe bleeding because it takes longer to correct clotting deficiencies compared to intravenous or intramuscular administration.

B) Second-Line Therapy:

Prothrombin Complex Concentrate (PCC):

Indication: Used in cases of severe VKDB when FFP is not available or sufficient.

Mechanism: Contains high concentrations of clotting factors II, VII, IX, and X.

Outcome: Provides rapid correction of clotting factor deficiencies in life-threatening bleeding.

8. Routine Monitoring and Follow-Up

A) Coagulation Studies:

Frequency: Repeat testing every few hours after vitamin K administration to ensure improvement in PT and aPTT.

Purpose: To monitor the response to therapy and ensure coagulation abnormalities are resolving.

B) Neurological Monitoring:

Purpose: In infants with suspected or confirmed intracranial haemorrhage, regular neurological assessments are needed to detect signs of increased intracranial pressure or other complications.

C) Long-Term Follow-Up:

Purpose: Late VKDB can have long-term consequences, particularly if intracranial haemorrhage occurs. Regular developmental assessments may be needed for infants who experienced significant bleeding episodes.

9. Complications of VKDB

A) Intracranial Haemorrhage:

Cause: Bleeding into the brain due to severe vitamin K deficiency, particularly in late VKDB.

Management: Immediate administration of vitamin K and fresh frozen plasma (FFP), with neurosurgical intervention if needed.

Outcome: Can lead to long-term neurological deficits, developmental delays, or death if not treated promptly.

B) Severe Anaemia and Shock:

Cause: Massive blood loss from gastrointestinal or internal bleeding.

Management: Blood transfusion and volume resuscitation, along with correction of the clotting defect.

C) Permanent Neurological Impairment:

Cause: Untreated or severe intracranial haemorrhage can cause irreversible brain damage.

Management: Early intervention with vitamin K and supportive care to prevent long-term complications.

Summary of Key Points for Haemorrhagic Disease of the Newborn (VKDB)

VKDB (Vitamin K Deficiency Bleeding) occurs in newborns due to inadequate levels of **vitamin K**, leading to a deficiency in **clotting factors II, VII, IX, and X**, and resulting in bleeding.

Diagnosis is confirmed by **prolonged PT**, normal platelet count, and rapid response to vitamin K administration.

Prevention involves routine **vitamin K prophylaxis** (IM or oral) given to all newborns at birth.

Treatment of VKDB includes **vitamin K administration** and, in severe cases, **fresh frozen plasma (FFP)** or **prothrombin complex concentrate (PCC)** for immediate clotting support.

Monitoring involves regular coagulation studies and neurological assessments, particularly in cases with suspected intracranial haemorrhage.

235. High INR and Bleeding

1. Detailed Definition of High INR and Bleeding

International Normalised Ratio (INR) is a standardised measurement used to assess the time it takes for blood to clot, particularly in patients on **warfarin** or other **vitamin K antagonists** (VKAs). A **high INR** indicates that the blood is taking too long to clot, which increases the risk of **bleeding**.

The target INR range varies based on the indication for anticoagulation, typically between **2.0 and 3.0** for conditions like **atrial fibrillation** or **venous thromboembolism (VTE)**. A high INR (>3.0) increases the risk of **spontaneous bleeding** and **life-threatening haemorrhages**.

Causes of elevated INR include:

Excessive warfarin dose.

Drug interactions (e.g., antibiotics, amiodarone, NSAIDs).

Liver disease.

Nutritional deficiencies (e.g., vitamin K deficiency).

Alcohol consumption.

2. Common Presenting Complaints and Symptoms of High INR and Bleeding

Patients with a high INR are at increased risk of bleeding, which can present in a variety of ways depending on the severity and location of the bleeding.

A) Mild to Moderate Bleeding:

Epistaxis: Recurrent or prolonged nosebleeds.

Gingival Bleeding: Bleeding from the gums.

Easy Bruising: Unexplained or extensive bruises, even after minor trauma.

Haematuria: Blood in the urine, presenting as pink, red, or brown urine.

Menorrhagia: Heavy menstrual bleeding in women.

B) Severe or Life-Threatening Bleeding:

Gastrointestinal Bleeding: Vomiting blood (haematemesis), black tarry stools (melaena), or bright red blood per rectum.

Intracranial Haemorrhage: Symptoms include severe headache, confusion, vomiting, seizures, or sudden neurological deficits like weakness, speech difficulty, or altered consciousness.

Retroperitoneal Bleeding: Abdominal or back pain, often associated with significant blood loss.

Haemarthrosis: Bleeding into joints, causing pain, swelling, and restricted movement.

Ocular Bleeding: Vision changes, floaters, or bleeding in the eye.

3. First-Line Investigations for High INR and Bleeding

Several tests are necessary to assess the severity of bleeding, identify the cause of the elevated INR, and guide management.

A) International Normalised Ratio (INR):

Purpose: To measure the time it takes for blood to clot.

Findings: An INR >3.0 increases the risk of bleeding, while an INR >5.0 is considered a major risk for spontaneous bleeding. INR >9.0 is a medical emergency requiring immediate reversal.

B) Full Blood Count (FBC):

Purpose: To assess haemoglobin levels and platelet count.

Findings: Low haemoglobin may indicate significant blood loss, while platelet count is usually normal in isolated anticoagulant-related bleeding.

C) Liver Function Tests (LFTs):

Purpose: To assess for liver dysfunction, which can lead to increased INR due to reduced synthesis of clotting factors.

Findings: Abnormal LFTs may indicate underlying liver disease contributing to a prolonged INR.

D) Renal Function Tests:

Purpose: To evaluate kidney function, especially in patients on medications that affect warfarin metabolism.

Findings: Impaired renal function may exacerbate warfarin toxicity.

E) Coagulation Studies:

Prothrombin Time (PT) and Activated Partial Thromboplastin Time (aPTT):

Purpose: To assess the extrinsic (PT) and intrinsic (aPTT) clotting pathways.

Findings: Prolonged PT in the context of elevated INR confirms a defect in the extrinsic pathway due to warfarin or vitamin K deficiency. aPTT may also be prolonged in severe cases of anticoagulant overdose.

F) Imaging Studies (if indicated):

CT Brain (if intracranial haemorrhage is suspected):

Purpose: To assess for signs of intracranial bleeding.

Findings: Presence of blood in the brain parenchyma, subarachnoid space, or ventricles.

Upper or Lower GI Endoscopy (if gastrointestinal bleeding is suspected):

Purpose: To identify the source of gastrointestinal bleeding (e.g., peptic ulcer, varices).

Findings: Visualisation of active bleeding, ulcers, or erosions.

4. Explanation of Investigations

a) International Normalised Ratio (INR):

Procedure: A blood sample is tested to determine how long it takes for blood to clot. INR is calculated based on the patient's prothrombin time (PT) compared to a normal control.

Interpretation: An elevated INR indicates prolonged clotting time and increased bleeding risk. An INR >5.0 is associated with a higher risk of bleeding, while an INR >9.0 is a critical value requiring urgent intervention.

5. Diagnostic Criteria for High INR and Bleeding

The diagnosis of high INR with bleeding is confirmed based on:

Elevated INR: INR >3.0, with increasing bleeding risk as the INR rises above 5.0.

Clinical Evidence of Bleeding: Visible bleeding or bleeding confirmed by imaging or endoscopy (e.g., intracranial or gastrointestinal haemorrhage).

History of Anticoagulant Use: Most cases of elevated INR occur in patients on warfarin or other vitamin K antagonists.

Exclusion of Other Causes of Bleeding: Rule out other causes such as thrombocytopenia, liver disease, or coagulopathies unrelated to warfarin.

6. First-Line Therapy According to Guidelines

Management of high INR with bleeding depends on the **INR level**, **presence of bleeding**, and the severity of the situation. **NICE guidelines** recommend the following approach for warfarin reversal:

A) For INR 4.5-10 Without Bleeding:

Omit Warfarin:

Withhold warfarin and recheck INR in 24-48 hours.

Low-Dose Oral Vitamin K (1-2 mg):

Consider for INR >6.0 to reduce INR more rapidly, especially if the patient is at risk of bleeding.

B) For INR >10 Without Bleeding:

Vitamin K 2-5 mg Orally or Intravenously:

Oral Vitamin K: Recheck INR in 24 hours; if still elevated, give another dose.

Intravenous Vitamin K: Preferred if faster INR reduction is needed.

Outcome: Vitamin K promotes clotting factor production in the liver and reverses the effects of warfarin over several hours.

C) For High INR with Bleeding:

Stop Warfarin:

Immediately stop warfarin therapy.

Prothrombin Complex Concentrate (PCC):

Dose: 25-50 IU/kg, depending on the INR and severity of bleeding.

Mechanism: Contains clotting factors II, VII, IX, and X, providing rapid reversal of warfarin-induced coagulopathy.

Outcome: PCC works within minutes, rapidly restoring clotting ability.

Fresh Frozen Plasma (FFP) (if PCC is unavailable):

Dose: 15-20 mL/kg.

Mechanism: Contains clotting factors to help reverse anticoagulation, though it is less effective and slower than PCC.

Outcome: Provides temporary correction of coagulation defects.

Intravenous Vitamin K (5-10 mg):

Mechanism: Promotes the synthesis of clotting factors in the liver, taking several hours to exert its effect.

Outcome: Slower than PCC but essential for longer-term INR correction.

D) Supportive Care:

Transfusion: If the patient has significant anaemia due to bleeding (e.g., haemoglobin <70-80 g/L).

Monitor INR and Haemoglobin Levels: Repeat INR and haemoglobin every 6-12 hours to ensure effective reversal and stabilisation of the patient.

7. Common Contraindications and Second-Line Therapy

A) Contraindications:

Subcutaneous Vitamin K: Should not be used as it is absorbed unpredictably, leading to delayed or inadequate INR correction.

Oral Vitamin K: Should be avoided in patients with severe or life-threatening bleeding, as the onset of action is slower than intravenous administration.

B) Second-Line Therapy:

Recombinant Activated Factor VII (rFVIIa):

Indication: For patients with life-threatening bleeding who do not respond to PCC or FFP.

Mechanism: Activates the clotting cascade directly, bypassing the need for vitamin K-dependent factors.

Outcome: Provides rapid but temporary haemostatic control.

Surgical Intervention:

Indication: For cases of ongoing or uncontrollable bleeding (e.g., gastrointestinal perforation or intracranial haemorrhage).

Outcome: Surgery may be needed to stop the source of bleeding and stabilise the patient.

8. Routine Monitoring and Follow-Up

A) INR Monitoring:

Frequency: Repeat INR every 6-12 hours after initiating reversal therapy to ensure effective correction. INR should then be monitored daily until it stabilises within the target range.

B) Haemoglobin and Platelet Counts:

Purpose: To assess for ongoing bleeding or the need for transfusion.

C) Liver Function Tests:

Frequency: Monitor periodically in patients with liver disease or impaired liver function, as this can affect clotting factor production and contribute to elevated INR.

9. Complications of High INR and Bleeding

A) Intracranial Haemorrhage:

Cause: Severe elevation of INR, particularly in elderly patients or those with a history of head trauma.

Management: Requires immediate reversal of INR and neurosurgical intervention if indicated.

B) Gastrointestinal Haemorrhage:

Cause: High INR can lead to upper or lower gastrointestinal bleeding, particularly in patients with peptic ulcers or oesophageal varices.

Management: Endoscopic intervention, transfusions, and rapid INR correction.

C) Anaemia and Shock:

Cause: Severe blood loss from uncontrolled bleeding.

Management: Transfusions and volume resuscitation, along with correction of the underlying coagulopathy.

Summary of Key Points for High INR and Bleeding

High INR results in an increased risk of **bleeding**, especially in patients on **warfarin** or other **vitamin K antagonists**.

Diagnosis is confirmed by **elevated INR** and evidence of bleeding, with **INR >5.0** indicating a high risk of bleeding and **INR >9.0** representing a medical emergency.

Management includes withholding warfarin, administering **vitamin K**, and using **prothrombin complex concentrate (PCC)** or **fresh frozen plasma (FFP)** to rapidly reverse coagulopathy in severe cases.

Monitoring involves regular INR and haemoglobin checks, with attention to preventing complications like **intracranial haemorrhage** and **gastrointestinal bleeding**.

236. Hyposplenism and Splenectomy

1. Detailed Definition of Hyposplenism and Splenectomy

Hyposplenism refers to reduced or absent splenic function, while **splenectomy** is the surgical removal of the spleen. Both conditions result in impaired immune function, particularly in defending against encapsulated bacteria, because the spleen plays a crucial role in filtering blood, producing antibodies, and removing pathogens like bacteria and damaged red blood cells.

Hyposplenism can occur due to various conditions, such as **sickle cell disease**, **coeliac disease**, or **rheumatoid arthritis**, where the spleen becomes non-functional (functional asplenia).

Splenectomy can be performed for various reasons, including trauma, haematological disorders (e.g., **hereditary spherocytosis**, **idiopathic thrombocytopenic purpura**), or splenic tumours.

The spleen is important for:

Phagocytosis of encapsulated bacteria (e.g., **Streptococcus pneumoniae**, **Haemophilus influenzae**, **Neisseria meningitidis**).

Antibody production, particularly IgM.

Filtration of damaged or old red blood cells.

2. Common Presenting Complaints and Symptoms of Hyposplenism and Splenectomy

After splenectomy or in cases of hyposplenism, patients are at increased risk of infections and may present with the following:

A) Increased Risk of Infections:

Recurrent Infections: Particularly from encapsulated bacteria (e.g., **pneumonia**, **meningitis**, **septicaemia**).

Overwhelming Post-Splenectomy Infection (OPSI): A life-threatening condition characterised by rapid onset of sepsis, typically due to **Streptococcus pneumoniae**, **Neisseria meningitidis**, or **Haemophilus influenzae**. It often presents with:

High fever, chills, and rigors.

Rapid onset of septic shock (hypotension, tachycardia, confusion, multi-organ failure).

Disseminated intravascular coagulation (DIC) and petechiae.

B) Haematological Changes:

Thrombocytosis: Increased platelet count is common after splenectomy, due to the loss of the spleen's role in platelet sequestration.

Howell-Jolly Bodies: Small, round inclusions of DNA remnants in red blood cells, seen on a blood film in hyposplenism or post-splenectomy.

Target Cells: Abnormal red blood cells seen in patients without splenic function.

C) Other Symptoms:

Mild Anaemia: Due to the reduced clearance of old or damaged red blood cells.

Fatigue: Due to a combination of anaemia and recurrent infections.

3. First-Line Investigations for Hyposplenism and Splenectomy

A variety of tests can help assess splenic function and the patient's risk of complications following splenectomy or in hyposplenism.

A) Full Blood Count (FBC):

Purpose: To assess for thrombocytosis and the presence of red cell abnormalities.

Findings:

Thrombocytosis: Increased platelet count, especially after splenectomy.

Mild Anaemia: May be present if there is ineffective erythropoiesis or haemolysis.

Howell-Jolly Bodies: Indicate absent or reduced splenic function.

B) Blood Film:

Purpose: To assess red blood cell morphology and look for signs of hyposplenism.

Findings:

Howell-Jolly Bodies: DNA remnants in red blood cells.

Target Cells: Abnormal red blood cells.

Pappenheimer Bodies: Iron-containing inclusions in red blood cells.

C) Platelet Count:

Purpose: To monitor for **thrombocytosis** after splenectomy, which can increase the risk of thrombosis.

Findings: Platelet count often rises after splenectomy but should be monitored to prevent thrombotic complications.

D) Immunological Tests (if indicated):

Purpose: To assess immune function, particularly antibody production.

Findings: Reduced **IgM** levels and impaired opsonisation of encapsulated organisms in severe hyposplenism.

4. Explanation of Investigations

a) Blood Film:

Procedure: A blood smear is stained and examined under a microscope to look for specific red blood cell abnormalities that indicate splenic dysfunction.

Interpretation: The presence of **Howell-Jolly bodies** or **target cells** indicates that the spleen is not effectively filtering the blood and removing defective red blood cells.

5. Diagnostic Criteria for Hyposplenism and Splenectomy

The diagnosis of hyposplenism or splenectomy is typically based on clinical history (i.e., a history of splenectomy) and the presence of the following features:
